percent-sign	'%'	ampersand	'&'
apostrophe	'\''	left-parenthesis	'('
right-parenthesis	')'	asterisk	'*'
plus-sign	'+'	comma	','
hyphen	'-'	hyphen-minus	'-'
period	'.'	full-stop	'.'
slash	'/'	solidus	'/'
zero	'0'	one	'1'
two	'2'	three	'3'
four	'4'	five	'5'
six	'6'	seven	'7'
eight	'8'	nine	'9'
colon	':'	semicolon	';'
less-than-sign	'<'	equals-sign	'='
greater-than-sign	'>'	question-mark	'?'
commercial-at	'@'	left-square-bracket	'['
backslash	'\"'	reverse-solidus	'\"'
right-square-bracket	']'	circumflex	'^'
circumflex-accent	'^'	underscore	'_'

low-line	'_'	grave-accent	'`'
left-brace	'{'	left-curly-bracket	'{'
vertical-line	' '	right-brace	'}'
right-curly-bracket	'}'	tilde	'~'
DEL	177		

```
mysql> SELECT '~' REGEXP '[[.~.]]';      -> 1
mysql> SELECT '~' REGEXP '[[.tilde.]]';  -> 1
```

- `[=character_class=]`

Within a bracket expression (written using `[` and `]`), `[=character_class=]` represents an equivalence class. It matches all characters with the same collation value, including itself. For example, if `o` and `(+)` are the members of an equivalence class, then `[[=o=]]`, `[[=(+)=]]`, and `[o(+)]` are all synonymous. An equivalence class may not be used as an endpoint of a range.

- `[:character_class:]`

Within a bracket expression (written using `[` and `]`), `[:character_class:]` represents a character class that matches all characters belonging to that class. The following table lists the standard class names. These names stand for the character classes defined in the [ctype\(3\)](#) manual page. A particular locale may provide other class names. A character class may not be used as an endpoint of a range.

<code>alnum</code>	Alphanumeric characters
<code>alpha</code>	Alphabetic characters
<code>blank</code>	Whitespace characters
<code>cntrl</code>	Control characters
<code>digit</code>	Digit characters
<code>graph</code>	Graphic characters
<code>lower</code>	Lowercase alphabetic characters
<code>print</code>	Graphic or space characters
<code>punct</code>	Punctuation characters
<code>space</code>	Space, tab, newline, and carriage return
<code>upper</code>	Uppercase alphabetic characters
<code>xdigit</code>	Hexadecimal digit characters

```
mysql> SELECT 'justalnums' REGEXP '[[[:alnum:]]+];      -> 1
mysql> SELECT '!!!' REGEXP '[[[:alnum:]]+];            -> 0
```

- `[:<:]]`, `[:>:]]`

These markers stand for word boundaries. They match the beginning and end of words, respectively. A word is a sequence of word characters that is not preceded by or followed by word characters. A word character is an alphanumeric character in the `alnum` class or an underscore (`_`).

```
mysql> SELECT 'a word a' REGEXP '[:<:]word[:>:]]';    -> 1
mysql> SELECT 'a xword a' REGEXP '[:<:]word[:>:]]';    -> 0
```

To use a literal instance of a special character in a regular expression, precede it by two backslash (`\`) characters. The MySQL parser interprets one of the backslashes, and the regular expression library interprets the other. For example, to match the string `1+2` that contains the special `+` character, only the last of the following regular expressions is the correct one:

```
mysql> SELECT '1+2' REGEXP '1+2';      -> 0
mysql> SELECT '1+2' REGEXP '1\+2';     -> 0
mysql> SELECT '1+2' REGEXP '1\\+2';     -> 1
```

11.5. Numeric Functions

Name	Description
ABS()	Return the absolute value
ACOS()	Return the arc cosine
ASIN()	Return the arc sine
ATAN2(), ATAN()	Return the arc tangent of the two arguments
ATAN()	Return the arc tangent
/	Division operator
CEILING(), CEIL()	Return the smallest integer value not less than the argument
COS()	Return the cosine
COT()	Return the cotangent
CRC32() (v4.1.0)	Compute a cyclic redundancy check value
DEGREES()	Convert radians to degrees
DIV (v4.1.0)	Integer division
EXP()	Raise to the power of
FLOOR()	Return the largest integer value not greater than the argument
MOD()	Return the remainder
LN()	Return the natural logarithm of the argument
LOG10()	Return the base-10 logarithm of the argument
LOG2()	Return the base-2 logarithm of the argument
LOG()	Return the natural logarithm of the first argument
-	Minus operator
%	Modulo operator
PI()	Return the value of pi
+	Addition operator
POW(), POWER()	Return the argument raised to the specified power
RADIANS()	Return argument converted to radians
RAND()	Return a random floating-point value
ROUND()	Round the argument
SIGN()	Return the sign of the argument
SIN()	Return the sine of the argument
SQRT()	Return the square root of the argument
TAN()	Return the tangent of the argument
*	Times operator
TRUNCATE()	Truncate to specified number of decimal places
-	Change the sign of the argument

11.5.1. Arithmetic Operators

Name	Description
/	Division operator
DIV (v4.1.0)	Integer division
-	Minus operator
%	Modulo operator
+	Addition operator

Name	Description
*	Times operator
-	Change the sign of the argument

The usual arithmetic operators are available. The precision of the result is determined according to the following rules:

- Note that in the case of `-`, `+`, and `*`, the result is calculated with `BIGINT` (64-bit) precision if both arguments are integers.
- If one of the arguments is an unsigned integer, and the other argument is also an integer, the result is an unsigned integer.
- If any of the operands of a `+`, `-`, `/`, `*`, `%` is a real or string value, then the precision of the result is the precision of the argument with the maximum precision.
- In multiplication and division, the precision of the result when using two exact values is the precision of the first argument + the value of the `div_precision_increment` global variable. For example, the expression `5.05 / 0.0014` would have a precision of six decimal places (`3607.142857`).

These rules are applied for each operation, such that nested calculations imply the precision of each component. Hence, `(14620 / 9432456) / (24250 / 9432456)`, would resolve first to `(0.0014) / (0.0026)`, with the final result having 8 decimal places (`0.57692308`).

Because of these rules and the method they are applied, care should be taken to ensure that components and sub-components of a calculation use the appropriate level of precision. See [Section 11.9, “Cast Functions and Operators”](#).

- `+`

Addition:

```
mysql> SELECT 3+5;
-> 8
```

- `-`

Subtraction:

```
mysql> SELECT 3-5;
-> -2
```

- `-`

Unary minus. This operator changes the sign of the argument.

```
mysql> SELECT - 2;
-> -2
```

Note

If this operator is used with a `BIGINT`, the return value is also a `BIGINT`. This means that you should avoid using `-` on integers that may have the value of -2^{63} .

- `*`

Multiplication:

```
mysql> SELECT 3*5;
-> 15
mysql> SELECT 18014398509481984*18014398509481984.0;
-> 324518553658426726783156020576256.0
mysql> SELECT 18014398509481984*18014398509481984;
-> 0
```

The result of the last expression is incorrect because the result of the integer multiplication exceeds the 64-bit range of **BIGINT** calculations. (See [Section 10.2, “Numeric Types”](#).)

- /

Division:

```
mysql> SELECT 3/5;
-> 0.60
```

Division by zero produces a **NULL** result:

```
mysql> SELECT 102/(1-1);
-> NULL
```

A division is calculated with **BIGINT** arithmetic only if performed in a context where its result is converted to an integer.

- DIV

Integer division. Similar to **FLOOR()**, but is safe with **BIGINT** values.

```
mysql> SELECT 5 DIV 2;
-> 2
```

- N % M

Modulo operation. Returns the remainder of *N* divided by *M*. For more information, see the description for the **MOD()** function in [Section 11.5.2, “Mathematical Functions”](#).

11.5.2. Mathematical Functions

Name	Description
ABS()	Return the absolute value
ACOS()	Return the arc cosine
ASIN()	Return the arc sine
ATAN2(), ATAN()	Return the arc tangent of the two arguments
ATAN()	Return the arc tangent
CEILING(), CEIL()	Return the smallest integer value not less than the argument
COS()	Return the cosine
COT()	Return the cotangent
CRC32() (v4.1.0)	Compute a cyclic redundancy check value
DEGREES()	Convert radians to degrees
EXP()	Raise to the power of
FLOOR()	Return the largest integer value not greater than the argument
MOD()	Return the remainder
LN()	Return the natural logarithm of the argument
LOG10()	Return the base-10 logarithm of the argument
LOG2()	Return the base-2 logarithm of the argument
LOG()	Return the natural logarithm of the first argument
PI()	Return the value of pi
POW(), POWER()	Return the argument raised to the specified power
RADIANS()	Return argument converted to radians
RAND()	Return a random floating-point value

Name	Description
ROUND()	Round the argument
SIGN()	Return the sign of the argument
SIN()	Return the sine of the argument
SQRT()	Return the square root of the argument
TAN()	Return the tangent of the argument
TRUNCATE()	Truncate to specified number of decimal places

All mathematical functions return **NULL** in the event of an error.

- [ABS\(X\)](#)

Returns the absolute value of *X*.

```
mysql> SELECT ABS(2);
-> 2
mysql> SELECT ABS(-32);
-> 32
```

This function is safe to use with **BIGINT** values.

- [ACOS\(X\)](#)

Returns the arc cosine of *X*, that is, the value whose cosine is *X*. Returns **NULL** if *X* is not in the range **-1** to **1**.

```
mysql> SELECT ACOS(1);
-> 0
mysql> SELECT ACOS(1.0001);
-> NULL
mysql> SELECT ACOS(0);
-> 1.5707963267949
```

- [ASIN\(X\)](#)

Returns the arc sine of *X*, that is, the value whose sine is *X*. Returns **NULL** if *X* is not in the range **-1** to **1**.

```
mysql> SELECT ASIN(0.2);
-> 0.20135792079033
mysql> SELECT ASIN('foo');
```

```
+-----+
| ASIN('foo') |
+-----+
| 0 |
+-----+
1 row in set, 1 warning (0.00 sec)
```

```
mysql> SHOW WARNINGS;
```

```
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1292 | Truncated incorrect DOUBLE value: 'foo' |
+-----+-----+-----+
```

- [ATAN\(X\)](#)

Returns the arc tangent of *X*, that is, the value whose tangent is *X*.

```
mysql> SELECT ATAN(2);
-> 1.1071487177941
mysql> SELECT ATAN(-2);
-> -1.1071487177941
```

- [ATAN\(Y,X\)](#), [ATAN2\(Y,X\)](#)

Returns the arc tangent of the two variables *X* and *Y*. It is similar to calculating the arc tangent of *Y* / *X*, except that the signs of

both arguments are used to determine the quadrant of the result.

```
mysql> SELECT ATAN(-2,2);
-> -0.78539816339745
mysql> SELECT ATAN2(PI(),0);
-> 1.5707963267949
```

- **CEILING(*X*)**, **CEIL(*X*)**

Returns the smallest integer value not less than *X*. **CEILING()** and **CEIL()** are synonymous.

```
mysql> SELECT CEILING(1.23);
-> 2
mysql> SELECT CEIL(-1.23);
-> -1
```

For exact-value numeric arguments, the return value has an exact-value numeric type. For string or floating-point arguments, the return value has a floating-point type.

- **COS(*X*)**

Returns the cosine of *X*, where *X* is given in radians.

```
mysql> SELECT COS(PI());
-> -1
```

- **COT(*X*)**

Returns the cotangent of *X*.

```
mysql> SELECT COT(12);
-> -1.5726734063977
mysql> SELECT COT(0);
-> NULL
```

- **CRC32(*expr*)**

Computes a cyclic redundancy check value and returns a 32-bit unsigned value. The result is **NULL** if the argument is **NULL**. The argument is expected to be a string and (if possible) is treated as one if it is not.

```
mysql> SELECT CRC32('MySQL');
-> 3259397556
mysql> SELECT CRC32('mysql');
-> 2501908538
```

- **DEGREES(*X*)**

Returns the argument *X*, converted from radians to degrees.

```
mysql> SELECT DEGREES(PI());
-> 180
mysql> SELECT DEGREES(PI() / 2);
-> 90
```

- **EXP(*X*)**

Returns the value of *e* (the base of natural logarithms) raised to the power of *X*.

```
mysql> SELECT EXP(2);
-> 7.3890560989307
mysql> SELECT EXP(-2);
-> 0.13533528323661
mysql> SELECT EXP(0);
-> 1
```

- **FLOOR(*X*)**

Returns the largest integer value not greater than *X*.

```
mysql> SELECT FLOOR(1.23);
-> 1
mysql> SELECT FLOOR(-1.23);
-> -2
```

For exact-value numeric arguments, the return value has an exact-value numeric type. For string or floating-point arguments, the return value has a floating-point type.

- **FORMAT(*X*, *D*)**

Formats the number *X* to a format like '*#, ###, ###.##*', rounded to *D* decimal places, and returns the result as a string. For details, see [Section 11.4, “String Functions”](#).

- **LN(*X*)**

Returns the natural logarithm of *X*; that is, the base-*e* logarithm of *X*.

```
mysql> SELECT LN(2);
-> 0.69314718055995
mysql> SELECT LN(-2);
-> NULL
```

This function is synonymous with **LOG(*X*)**.

- **LOG(*X*), LOG(*B*, *X*)**

If called with one parameter, this function returns the natural logarithm of *X*.

```
mysql> SELECT LOG(2);
-> 0.69314718055995
mysql> SELECT LOG(-2);
-> NULL
```

If called with two parameters, this function returns the logarithm of *X* for an arbitrary base *B*.

```
mysql> SELECT LOG(2, 65536);
-> 16
mysql> SELECT LOG(10, 100);
-> 2
```

LOG(*B*, *X*) is equivalent to **LOG(*X*) / LOG(*B*)**.

- **LOG2(*X*)**

Returns the base-2 logarithm of *X*.

```
mysql> SELECT LOG2(65536);
-> 16
mysql> SELECT LOG2(-100);
-> NULL
```

LOG2() is useful for finding out how many bits a number requires for storage. This function is equivalent to the expression **LOG(*X*) / LOG(2)**.

- **LOG10(*X*)**

Returns the base-10 logarithm of *X*.

```
mysql> SELECT LOG10(2);
-> 0.30102999566398
mysql> SELECT LOG10(100);
-> 2
mysql> SELECT LOG10(-100);
-> NULL
```

LOG10(*X*) is equivalent to **LOG(10, *X*)**.

- **MOD(*N*, *M*), *N* % *M*, *N* MOD *M***

Modulo operation. Returns the remainder of N divided by M .

```
mysql> SELECT MOD(234, 10);
-> 4
mysql> SELECT 253 % 7;
-> 1
mysql> SELECT MOD(29,9);
-> 2
mysql> SELECT 29 MOD 9;
-> 2
```

This function is safe to use with **BIGINT** values.

MOD() also works on values that have a fractional part and returns the exact remainder after division:

```
mysql> SELECT MOD(34.5,3);
-> 1.5
```

MOD(N , 0) returns **NULL**.

- **PI()**

Returns the value of π (pi). The default number of decimal places displayed is seven, but MySQL uses the full double-precision value internally.

```
mysql> SELECT PI();
-> 3.141593
mysql> SELECT PI()+0.00000000000000000000;
-> 3.141592653589793116
```

- **POW(X , Y), POWER(X , Y)**

Returns the value of X raised to the power of Y .

```
mysql> SELECT POW(2,2);
-> 4
mysql> SELECT POW(2, -2);
-> 0.25
```

- **RADIANS(X)**

Returns the argument X , converted from degrees to radians. (Note that π radians equals 180 degrees.)

```
mysql> SELECT RADIANS(90);
-> 1.5707963267949
```

- **RAND(), RAND(N)**

Returns a random floating-point value v in the range $0 \leq v < 1.0$. If a constant integer argument N is specified, it is used as the seed value, which produces a repeatable sequence of column values.

```
mysql> SELECT RAND();
-> 0.9233482386203
mysql> SELECT RAND(20);
-> 0.15888261251047
mysql> SELECT RAND(20);
-> 0.15888261251047
mysql> SELECT RAND();
-> 0.63553050033332
mysql> SELECT RAND();
-> 0.70100469486881
mysql> SELECT RAND(20);
-> 0.15888261251047
```

With a constant initializer, the seed is initialized once when the statement is compiled, prior to execution. As of MySQL 5.1.16, if a non-constant initializer (such as a column name) is used as the argument, the seed is initialized with the value for each invocation of **RAND()**. (One implication of this is that for equal argument values, **RAND()** will return the same value each time.) From MySQL 5.1.3 to 5.1.15, non-constant arguments are disallowed. Before that, the effect of using a non-constant argument is undefined.

To obtain a random integer R in the range $i \leq R < j$, use the expression `FLOOR( $i$  + RAND() * ( $j$  -  $i$ ))`. For example, to obtain a random integer in the range the range $7 \leq R < 12$, you could use the following statement:

```
SELECT FLOOR(7 + (RAND() * 5));
```

You cannot use a column with `RAND()` values in an `ORDER BY` clause, because `ORDER BY` would evaluate the column multiple times. However, you can retrieve rows in random order like this:

```
mysql> SELECT * FROM tbl_name ORDER BY RAND();
```

`ORDER BY RAND()` combined with `LIMIT` is useful for selecting a random sample from a set of rows:

```
mysql> SELECT * FROM table1, table2 WHERE a=b AND c<d -> ORDER BY RAND() LIMIT 1000;
```

Note that `RAND()` in a `WHERE` clause is re-evaluated every time the `WHERE` is executed.

`RAND()` is not meant to be a perfect random generator, but instead is a fast way to generate *ad hoc* random numbers which is portable between platforms for the same MySQL version.

- **ROUND(X), ROUND(X , D)**

Rounds the argument X to D decimal places. The rounding algorithm depends on the data type of X . D defaults to 0 if not specified. D can be negative to cause D digits left of the decimal point of the value X to become zero.

```
mysql> SELECT ROUND(-1.23);
-> -1
mysql> SELECT ROUND(-1.58);
-> -2
mysql> SELECT ROUND(1.58);
-> 2
mysql> SELECT ROUND(1.298, 1);
-> 1.3
mysql> SELECT ROUND(1.298, 0);
-> 1
mysql> SELECT ROUND(23.298, -1);
-> 20
```

The return type is the same type as that of the first argument (assuming that it is integer, double, or decimal). This means that for an integer argument, the result is an integer (no decimal places):

```
mysql> SELECT ROUND(150.000,2), ROUND(150,2);
+-----+-----+
| ROUND(150.000,2) | ROUND(150,2) |
+-----+-----+
| 150.00 | 150 |
+-----+-----+
```

`ROUND()` uses the precision math library for exact-value arguments when the first argument is a decimal value:

- For exact-value numbers, `ROUND()` uses the “round half up” or “round toward nearest” rule: A value with a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negative. (In other words, it is rounded away from zero.) A value with a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative.
- For approximate-value numbers, the result depends on the C library. On many systems, this means that `ROUND()` uses the “round to nearest even” rule: A value with any fractional part is rounded to the nearest even integer.

The following example shows how rounding differs for exact and approximate values:

```
mysql> SELECT ROUND(2.5), ROUND(25E-1);
+-----+-----+
| ROUND(2.5) | ROUND(25E-1) |
+-----+-----+
| 3 | 2 |
+-----+-----+
```

For more information, see [Chapter 24, Precision Math](#).

- **SIGN(*X*)**

Returns the sign of the argument as **-1**, **0**, or **1**, depending on whether *X* is negative, zero, or positive.

```
mysql> SELECT SIGN(-32);
-> -1
mysql> SELECT SIGN(0);
-> 0
mysql> SELECT SIGN(234);
-> 1
```

- **SIN(*X*)**

Returns the sine of *X*, where *X* is given in radians.

```
mysql> SELECT SIN(PI());
-> 1.2246063538224e-16
mysql> SELECT ROUND(SIN(PI()));
-> 0
```

- **SQRT(*X*)**

Returns the square root of a non-negative number *X*.

```
mysql> SELECT SQRT(4);
-> 2
mysql> SELECT SQRT(20);
-> 4.4721359549996
mysql> SELECT SQRT(-16);
-> NULL
```

- **TAN(*X*)**

Returns the tangent of *X*, where *X* is given in radians.

```
mysql> SELECT TAN(PI());
-> -1.2246063538224e-16
mysql> SELECT TAN(PI()+1);
-> 1.5574077246549
```

- **TRUNCATE(*X*, *D*)**

Returns the number *X*, truncated to *D* decimal places. If *D* is **0**, the result has no decimal point or fractional part. *D* can be negative to cause *D* digits left of the decimal point of the value *X* to become zero.

```
mysql> SELECT TRUNCATE(1.223,1);
-> 1.2
mysql> SELECT TRUNCATE(1.999,1);
-> 1.9
mysql> SELECT TRUNCATE(1.999,0);
-> 1
mysql> SELECT TRUNCATE(-1.999,1);
-> -1.9
mysql> SELECT TRUNCATE(122,-2);
-> 100
mysql> SELECT TRUNCATE(10.28*100,0);
-> 1028
```

All numbers are rounded toward zero.

11.6. Date and Time Functions

This section describes the functions that can be used to manipulate temporal values. See [Section 10.3, “Date and Time Types”](#), for a description of the range of values each date and time type has and the valid formats in which values may be specified.

Name	Description
ADDDATE() (v4.1.1)	Add dates
ADDTIME() (v4.1.1)	Add time

Name	Description
CONVERT_TZ() (v4.1.3)	Convert from one timezone to another
CURDATE()	Return the current date
CURRENT_DATE() , CURRENT_DATE	Synonyms for CURDATE()
CURRENT_TIME() , CURRENT_TIME	Synonyms for CURTIME()
CURRENT_TIMESTAMP() , CURRENT_TIMESTAMP	Synonyms for NOW()
CURTIME()	Return the current time
DATE_ADD()	Add two dates
DATE_FORMAT()	Format date as specified
DATE_SUB()	Subtract two dates
DATE() (v4.1.1)	Extract the date part of a date or datetime expression
DATEDIFF() (v4.1.1)	Subtract two dates
DAY() (v4.1.1)	Synonym for DAYOFMONTH()
DAYNAME() (v4.1.21)	Return the name of the weekday
DAYOFMONTH()	Return the day of the month (1-31)
DAYOFWEEK()	Return the weekday index of the argument
DAYOFYEAR()	Return the day of the year (1-366)
EXTRACT	Extract part of a date
FROM_DAYS()	Convert a day number to a date
FROM_UNIXTIME()	Format date as a UNIX timestamp
GET_FORMAT() (v4.1.1)	Return a date format string
HOUR()	Extract the hour
LAST_DAY (v4.1.1)	Return the last day of the month for the argument
LOCALTIME() , LOCALTIME	Synonym for NOW()
LOCALTIMESTAMP , LOCALTIMESTAMP() (v4.0.6)	Synonym for NOW()
MAKEDATE() (v4.1.1)	Create a date from the year and day of year
MAKETIME (v4.1.1)	MAKETIME()
MICROSECOND() (v4.1.1)	Return the microseconds from argument
MINUTE()	Return the minute from the argument
MONTH()	Return the month from the date passed
MONTHNAME() (v4.1.21)	Return the name of the month
NOW()	Return the current date and time
PERIOD_ADD()	Add a period to a year-month
PERIOD_DIFF()	Return the number of months between periods
QUARTER()	Return the quarter from a date argument
SEC_TO_TIME()	Converts seconds to 'HH:MM:SS' format
SECOND()	Return the second (0-59)
STR_TO_DATE() (v4.1.1)	Convert a string to a date
SUBDATE()	When invoked with three arguments a synonym for DATE_SUB()
SUBTIME() (v4.1.1)	Subtract times
SYSDATE()	Return the time at which the function executes
TIME_FORMAT()	Format as time
TIME_TO_SEC()	Return the argument converted to seconds
TIME() (v4.1.1)	Extract the time portion of the expression passed

Name	Description
TIMEDIFF() (v4.1.1)	Subtract time
TIMESTAMP() (v4.1.1)	With a single argument, this function returns the date or datetime expression. With two arguments, the sum of the arguments
TIMESTAMPADD() (v5.0.0)	Add an interval to a datetime expression
TIMESTAMPDIFF() (v5.0.0)	Subtract an interval from a datetime expression
TO_DAYS()	Return the date argument converted to days
UNIX_TIMESTAMP()	Return a UNIX timestamp
UTC_DATE() (v4.1.1)	Return the current UTC date
UTC_TIME() (v4.1.1)	Return the current UTC time
UTC_TIMESTAMP() (v4.1.1)	Return the current UTC date and time
WEEK()	Return the week number
WEEKDAY()	Return the weekday index
WEEKOFYEAR() (v4.1.1)	Return the calendar week of the date (1-53)
YEAR()	Return the year
YEARWEEK()	Return the year and week

Here is an example that uses date functions. The following query selects all rows with a [date_col](#) value from within the last 30 days:

```
mysql> SELECT something FROM tbl_name
-> WHERE DATE_SUB(CURDATE(),INTERVAL 30 DAY) <= date_col;
```

Note that the query also selects rows with dates that lie in the future.

Functions that expect date values usually accept datetime values and ignore the time part. Functions that expect time values usually accept datetime values and ignore the date part.

Functions that return the current date or time each are evaluated only once per query at the start of query execution. This means that multiple references to a function such as [NOW\(\)](#) within a single query always produce the same result (for our purposes a single query also includes a call to a stored routine or trigger and all sub-routines called by that routine/trigger). This principle also applies to [CURDATE\(\)](#), [CURTIME\(\)](#), [UTC_DATE\(\)](#), [UTC_TIME\(\)](#), [UTC_TIMESTAMP\(\)](#), and to any of their synonyms.

The [CURRENT_TIMESTAMP\(\)](#), [CURRENT_TIME\(\)](#), [CURRENT_DATE\(\)](#), and [FROM_UNIXTIME\(\)](#) functions return values in the connection's current time zone, which is available as the value of the [time_zone](#) system variable. In addition, [UNIX_TIMESTAMP\(\)](#) assumes that its argument is a datetime value in the current time zone. See [Section 5.10.8, “MySQL Server Time Zone Support”](#).

Some date functions can be used with “zero” dates or incomplete dates such as '2001-11-00', whereas others cannot. Functions that extract parts of dates typically work with incomplete dates. For example:

```
mysql> SELECT DAYOFMONTH('2001-11-00'), MONTH('2005-00-00');
-> 0, 0
```

Other functions expect complete dates and return [NULL](#) for incomplete dates. These include functions that perform date arithmetic or that map parts of dates to names. For example:

```
mysql> SELECT DATE_ADD('2006-05-00',INTERVAL 1 DAY);
-> NULL
mysql> SELECT DAYNAME('2006-05-00');
-> NULL
```

- [ADDDATE\(date,INTERVAL expr unit\)](#), [ADDDATE\(expr,days\)](#)

When invoked with the [INTERVAL](#) form of the second argument, [ADDDATE\(\)](#) is a synonym for [DATE_ADD\(\)](#). The related function [SUBDATE\(\)](#) is a synonym for [DATE_SUB\(\)](#). For information on the [INTERVAL unit](#) argument, see the discussion for [DATE_ADD\(\)](#).

```
mysql> SELECT DATE_ADD('1998-01-02', INTERVAL 31 DAY);
-> '1998-02-02'
```

```
mysql> SELECT ADDDATE('1998-01-02', INTERVAL 31 DAY);
-> '1998-02-02'
```

When invoked with the *days* form of the second argument, MySQL treats it as an integer number of days to be added to *expr*.

```
mysql> SELECT ADDDATE('1998-01-02', 31);
-> '1998-02-02'
```

- **ADDTIME(*expr1*,*expr2*)**

ADDTIME() adds *expr2* to *expr1* and returns the result. *expr1* is a time or datetime expression, and *expr2* is a time expression.

```
mysql> SELECT ADDTIME('1997-12-31 23:59:59.999999',
-> '1 1:1:1.000002');
-> '1998-01-02 01:01:01.000001'
mysql> SELECT ADDTIME('01:00:00.999999', '02:00:00.999998');
-> '03:00:01.999997'
```

- **CONVERT_TZ(*dt*,*from_tz*,*to_tz*)**

CONVERT_TZ() converts a datetime value *dt* from the time zone given by *from_tz* to the time zone given by *to_tz* and returns the resulting value. Time zones are specified as described in [Section 5.10.8, “MySQL Server Time Zone Support”](#). This function returns **NULL** if the arguments are invalid.

If the value falls out of the supported range of the **TIMESTAMP** type when converted from *from_tz* to UTC, no conversion occurs. The **TIMESTAMP** range is described in [Section 10.1.2, “Overview of Date and Time Types”](#).

```
mysql> SELECT CONVERT_TZ('2004-01-01 12:00:00', 'GMT', 'MET');
-> '2004-01-01 13:00:00'
mysql> SELECT CONVERT_TZ('2004-01-01 12:00:00', '+00:00', '+10:00');
-> '2004-01-01 22:00:00'
```

Note

To use named time zones such as **'MET'** or **'Europe/Moscow'**, the time zone tables must be properly set up. See [Section 5.10.8, “MySQL Server Time Zone Support”](#), for instructions.

Before MySQL 5.1.17, if you intend to use **CONVERT_TZ()** while other tables are locked with **LOCK TABLES**, you must also lock the **mysql.time_zone_name** table. See [Section 12.4.5, “LOCK TABLES and UNLOCK TABLES Syntax”](#).

- **CURDATE()**

Returns the current date as a value in **'YYYY-MM-DD'** or **YYYYMMDD** format, depending on whether the function is used in a string or numeric context.

```
mysql> SELECT CURDATE();
-> '1997-12-15'
mysql> SELECT CURDATE() + 0;
-> 19971215
```

- **CURRENT_DATE, CURRENT_DATE()**

CURRENT_DATE and **CURRENT_DATE()** are synonyms for **CURDATE()**.

- **CURTIME()**

Returns the current time as a value in **'HH:MM:SS'** or **HHMMSS** format, depending on whether the function is used in a string or numeric context. The value is expressed in the current time zone.

```
mysql> SELECT CURTIME();
-> '23:50:26'
mysql> SELECT CURTIME() + 0;
-> 235026
```

- **CURRENT_TIME, CURRENT_TIME()**

`CURRENT_TIME` and `CURRENT_TIME()` are synonyms for `CURTIME()`.

- `CURRENT_TIMESTAMP`, `CURRENT_TIMESTAMP()`

`CURRENT_TIMESTAMP` and `CURRENT_TIMESTAMP()` are synonyms for `NOW()`.

- `DATE(expr)`

Extracts the date part of the date or datetime expression *expr*.

```
mysql> SELECT DATE('2003-12-31 01:02:03');
-> '2003-12-31'
```

- `DATEDIFF(expr1,expr2)`

`DATEDIFF()` returns *expr1* – *expr2* expressed as a value in days from one date to the other. *expr1* and *expr2* are date or date-and-time expressions. Only the date parts of the values are used in the calculation.

```
mysql> SELECT DATEDIFF('1997-12-31 23:59:59','1997-12-30');
-> 1
mysql> SELECT DATEDIFF('1997-11-30 23:59:59','1997-12-31');
-> -31
```

- `DATE_ADD(date,INTERVAL expr unit)`, `DATE_SUB(date,INTERVAL expr unit)`

These functions perform date arithmetic. *date* is a `DATETIME` or `DATE` value specifying the starting date. *expr* is an expression specifying the interval value to be added or subtracted from the starting date. *expr* is a string; it may start with a '-' for negative intervals. *unit* is a keyword indicating the units in which the expression should be interpreted.

The `INTERVAL` keyword and the *unit* specifier are not case sensitive.

The following table shows the expected form of the *expr* argument for each *unit* value.

<i>unit</i> Value	Expected <i>expr</i> Format
<code>MICROSECOND</code>	<code>MICROSECONDS</code>
<code>SECOND</code>	<code>SECONDS</code>
<code>MINUTE</code>	<code>MINUTES</code>
<code>HOURL</code>	<code>HOURS</code>
<code>DAY</code>	<code>DAYS</code>
<code>WEEK</code>	<code>WEEKS</code>
<code>MONTH</code>	<code>MONTHS</code>
<code>QUARTER</code>	<code>QUARTERS</code>
<code>YEAR</code>	<code>YEARS</code>
<code>SECOND_MICROSECOND</code>	<code>'SECONDS.MICROSECONDS'</code>
<code>MINUTE_MICROSECOND</code>	<code>'MINUTES.MICROSECONDS'</code>
<code>MINUTE_SECOND</code>	<code>'MINUTES:SECONDS'</code>
<code>HOURL_MICROSECOND</code>	<code>'HOURS.MICROSECONDS'</code>
<code>HOURL_SECOND</code>	<code>'HOURS:MINUTES:SECONDS'</code>
<code>HOURL_MINUTE</code>	<code>'HOURS:MINUTES'</code>
<code>DAY_MICROSECOND</code>	<code>'DAYS.MICROSECONDS'</code>
<code>DAY_SECOND</code>	<code>'DAYS HOURS:MINUTES:SECONDS'</code>
<code>DAY_MINUTE</code>	<code>'DAYS HOURS:MINUTES'</code>
<code>DAY_HOUR</code>	<code>'DAYS HOURS'</code>
<code>YEAR_MONTH</code>	<code>'YEARS-MONTHS'</code>

MySQL allows any punctuation delimiter in the *expr* format. Those shown in the table are the suggested delimiters. If the *date* argument is a *DATE* value and your calculations involve only *YEAR*, *MONTH*, and *DAY* parts (that is, no time parts), the result is a *DATE* value. Otherwise, the result is a *DATETIME* value.

Date arithmetic also can be performed using *INTERVAL* together with the *+* or *-* operator:

```
date + INTERVAL expr unit
date - INTERVAL expr unit
```

INTERVAL expr unit is allowed on either side of the *+* operator if the expression on the other side is a date or datetime value. For the *-* operator, *INTERVAL expr unit* is allowed only on the right side, because it makes no sense to subtract a date or datetime value from an interval.

```
mysql> SELECT '1997-12-31 23:59:59' + INTERVAL 1 SECOND;
-> '1998-01-01 00:00:00'
mysql> SELECT INTERVAL 1 DAY + '1997-12-31';
-> '1998-01-01'
mysql> SELECT '1998-01-01' - INTERVAL 1 SECOND;
-> '1997-12-31 23:59:59'
mysql> SELECT DATE_ADD('1997-12-31 23:59:59',
-> INTERVAL 1 SECOND);
-> '1998-01-01 00:00:00'
mysql> SELECT DATE_ADD('1997-12-31 23:59:59',
-> INTERVAL 1 DAY);
-> '1998-01-01 23:59:59'
mysql> SELECT DATE_ADD('1997-12-31 23:59:59',
-> INTERVAL '1:1' MINUTE_SECOND);
-> '1998-01-01 00:01:00'
mysql> SELECT DATE_SUB('1998-01-01 00:00:00',
-> INTERVAL '1 1:1:1' DAY_SECOND);
-> '1997-12-30 22:58:59'
mysql> SELECT DATE_ADD('1998-01-01 00:00:00',
-> INTERVAL '-1 10' DAY_HOUR);
-> '1997-12-30 14:00:00'
mysql> SELECT DATE_SUB('1998-01-02', INTERVAL 31 DAY);
-> '1997-12-02'
mysql> SELECT DATE_ADD('1992-12-31 23:59:59.000002',
-> INTERVAL '1.999999' SECOND_MICROSECOND);
-> '1993-01-01 00:00:01.000001'
```

If you specify an interval value that is too short (does not include all the interval parts that would be expected from the *unit* keyword), MySQL assumes that you have left out the leftmost parts of the interval value. For example, if you specify a *unit* of *DAY_SECOND*, the value of *expr* is expected to have days, hours, minutes, and seconds parts. If you specify a value like *'1:10'*, MySQL assumes that the days and hours parts are missing and the value represents minutes and seconds. In other words, *'1:10' DAY_SECOND* is interpreted in such a way that it is equivalent to *'1:10' MINUTE_SECOND*. This is analogous to the way that MySQL interprets *TIME* values as representing elapsed time rather than as a time of day.

If you add to or subtract from a date value something that contains a time part, the result is automatically converted to a datetime value:

```
mysql> SELECT DATE_ADD('1999-01-01', INTERVAL 1 DAY);
-> '1999-01-02'
mysql> SELECT DATE_ADD('1999-01-01', INTERVAL 1 HOUR);
-> '1999-01-01 01:00:00'
```

If you add *MONTH*, *YEAR_MONTH*, or *YEAR* and the resulting date has a day that is larger than the maximum day for the new month, the day is adjusted to the maximum days in the new month:

```
mysql> SELECT DATE_ADD('1998-01-30', INTERVAL 1 MONTH);
-> '1998-02-28'
```

Date arithmetic operations require complete dates and do not work with incomplete dates such as *'2006-07-00'* or badly malformed dates:

```
mysql> SELECT DATE_ADD('2006-07-00', INTERVAL 1 DAY);
-> NULL
mysql> SELECT '2005-03-32' + INTERVAL 1 MONTH;
-> NULL
```

- *DATE_FORMAT(date, format)*

Formats the *date* value according to the *format* string.

The following specifiers may be used in the *format* string. The ‘%’ character is required before format specifier characters.

Specifier	Description
%a	Abbreviated weekday name (Sun..Sat)
%b	Abbreviated month name (Jan..Dec)
%c	Month, numeric (0..12)
%D	Day of the month with English suffix (0th, 1st, 2nd, 3rd, ...)
%d	Day of the month, numeric (00..31)
%e	Day of the month, numeric (0..31)
%f	Microseconds (000000..999999)
%H	Hour (00..23)
%h	Hour (01..12)
%I	Hour (01..12)
%i	Minutes, numeric (00..59)
%j	Day of year (001..366)
%k	Hour (0..23)
%l	Hour (1..12)
%M	Month name (January..December)
%m	Month, numeric (00..12)
%p	AM or PM
%r	Time, 12-hour (hh:mm:ss followed by AM or PM)
%S	Seconds (00..59)
%s	Seconds (00..59)
%T	Time, 24-hour (hh:mm:ss)
%U	Week (00..53), where Sunday is the first day of the week
%u	Week (00..53), where Monday is the first day of the week
%V	Week (01..53), where Sunday is the first day of the week; used with %X
%v	Week (01..53), where Monday is the first day of the week; used with %x
%W	Weekday name (Sunday..Saturday)
%w	Day of the week (0=Sunday..6=Saturday)
%X	Year for the week where Sunday is the first day of the week, numeric, four digits; used with %V
%x	Year for the week, where Monday is the first day of the week, numeric, four digits; used with %v
%Y	Year, numeric, four digits
%y	Year, numeric (two digits)
%%	A literal ‘%’ character
%x	x, for any ‘x’ not listed above

Ranges for the month and day specifiers begin with zero due to the fact that MySQL allows the storing of incomplete dates such as '2004-00-00'.

As of MySQL 5.1.12, the language used for day and month names and abbreviations is controlled by the value of the `lc_time_names` system variable (Section 5.10.9, “MySQL Server Locale Support”).

As of MySQL 5.1.15, `DATE_FORMAT()` returns a string with a character set and collation given by `character_set_connection` and `collation_connection` so that it can return month and weekday names containing non-ASCII characters. Before 5.1.15, the return value is a binary string.

```
mysql> SELECT DATE_FORMAT('1997-10-04 22:23:00', '%W %M %Y');
-> 'Saturday October 1997'
mysql> SELECT DATE_FORMAT('1997-10-04 22:23:00', '%H:%i:%s');
-> '22:23:00'
mysql> SELECT DATE_FORMAT('1997-10-04 22:23:00',
                          '%D %y %a %d %m %b %j');
-> '4th 97 Sat 04 10 Oct 277'
mysql> SELECT DATE_FORMAT('1997-10-04 22:23:00',
                          '%H %k %I %r %T %S %w');
-> '22 22 10 10:23:00 PM 22:23:00 00 6'
mysql> SELECT DATE_FORMAT('1999-01-01', '%X %V');
-> '1998 52'
mysql> SELECT DATE_FORMAT('2006-06-00', '%d');
-> '00'
```

- `DATE_SUB(date, INTERVAL expr unit)`

See `DATE_ADD()`.

- `DAY(date)`

`DAY()` is a synonym for `DAYOFMONTH()`.

- `DAYNAME(date)`

Returns the name of the weekday for *date*. As of MySQL 5.1.12, the language used for the name is controlled by the value of the `lc_time_names` system variable (Section 5.10.9, “MySQL Server Locale Support”).

```
mysql> SELECT DAYNAME('1998-02-05');
-> 'Thursday'
```

- `DAYOFMONTH(date)`

Returns the day of the month for *date*, in the range 0 to 31.

```
mysql> SELECT DAYOFMONTH('1998-02-03');
-> 3
```

- `DAYOFWEEK(date)`

Returns the weekday index for *date* (1 = Sunday, 2 = Monday, ..., 7 = Saturday). These index values correspond to the ODBC standard.

```
mysql> SELECT DAYOFWEEK('1998-02-03');
-> 3
```

- `DAYOFYEAR(date)`

Returns the day of the year for *date*, in the range 1 to 366.

```
mysql> SELECT DAYOFYEAR('1998-02-03');
-> 34
```

- `EXTRACT(unit FROM date)`

The `EXTRACT()` function uses the same kinds of unit specifiers as `DATE_ADD()` or `DATE_SUB()`, but extracts parts from the date rather than performing date arithmetic.

```
mysql> SELECT EXTRACT(YEAR FROM '1999-07-02');
-> 1999
mysql> SELECT EXTRACT(YEAR_MONTH FROM '1999-07-02 01:02:03');
-> 199907
mysql> SELECT EXTRACT(DAY_MINUTE FROM '1999-07-02 01:02:03');
-> 20102
mysql> SELECT EXTRACT(MICROSECOND
                      FROM '2003-01-02 10:30:00.000123');
-> 123
```

- `FROM_DAYS(N)`

Given a day number *N*, returns a **DATE** value.

```
mysql> SELECT FROM_DAYS(729669);
-> '1997-10-07'
```

Use **FROM_DAYS()** with caution on old dates. It is not intended for use with values that precede the advent of the Gregorian calendar (1582). See [Section 11.7, “What Calendar Is Used By MySQL?”](#).

- **FROM_UNIXTIME(*unix_timestamp*), FROM_UNIXTIME(*unix_timestamp*, *format*)**

Returns a representation of the *unix_timestamp* argument as a value in 'YYYY-MM-DD HH:MM:SS' or YYYYMMDDHHMMSS format, depending on whether the function is used in a string or numeric context. The value is expressed in the current time zone. *unix_timestamp* is an internal timestamp value such as is produced by the **UNIX_TIMESTAMP()** function.

If *format* is given, the result is formatted according to the *format* string, which is used the same way as listed in the entry for the **DATE_FORMAT()** function.

```
mysql> SELECT FROM_UNIXTIME(875996580);
-> '1997-10-04 22:23:00'
mysql> SELECT FROM_UNIXTIME(875996580) + 0;
-> 19971004222300
mysql> SELECT FROM_UNIXTIME(UNIX_TIMESTAMP(),
-> '%Y %D %M %h:%i:%s %x');
-> '2003 6th August 06:22:58 2003'
```

Note: If you use **UNIX_TIMESTAMP()** and **FROM_UNIXTIME()** to convert between **TIMESTAMP** values and Unix timestamp values, the conversion is lossy because the mapping is not one-to-one in both directions. For details, see the description of the **UNIX_TIMESTAMP()** function.

- **GET_FORMAT(DATE|TIME|DATETIME, 'EUR'|'USA'|'JIS'|'ISO'|'INTERNAL')**

Returns a format string. This function is useful in combination with the **DATE_FORMAT()** and the **STR_TO_DATE()** functions.

The possible values for the first and second arguments result in several possible format strings (for the specifiers used, see the table in the **DATE_FORMAT()** function description). ISO format refers to ISO 9075, not ISO 8601.

Function Call	Result
GET_FORMAT(DATE, 'USA')	'%m.%d.%Y'
GET_FORMAT(DATE, 'JIS')	'%Y-%m-%d'
GET_FORMAT(DATE, 'ISO')	'%Y-%m-%d'
GET_FORMAT(DATE, 'EUR')	'%d.%m.%Y'
GET_FORMAT(DATE, 'INTERNAL')	'%Y%m%d'
GET_FORMAT(DATETIME, 'USA')	'%Y-%m-%d %H.%i.%s'
GET_FORMAT(DATETIME, 'JIS')	'%Y-%m-%d %H:%i:%s'
GET_FORMAT(DATETIME, 'ISO')	'%Y-%m-%d %H:%i:%s'
GET_FORMAT(DATETIME, 'EUR')	'%Y-%m-%d %H.%i.%s'
GET_FORMAT(DATETIME, 'INTERNAL')	'%Y%m%d%H%i%s'
GET_FORMAT(TIME, 'USA')	'%h:%i:%s %p'
GET_FORMAT(TIME, 'JIS')	'%H:%i:%s'
GET_FORMAT(TIME, 'ISO')	'%H:%i:%s'
GET_FORMAT(TIME, 'EUR')	'%H.%i.%s'
GET_FORMAT(TIME, 'INTERNAL')	'%H%i%s'

TIMESTAMP can also be used as the first argument to **GET_FORMAT()**, in which case the function returns the same values as for **DATETIME**.

```
mysql> SELECT DATE_FORMAT('2003-10-03', GET_FORMAT(DATE, 'EUR'));
-> '03.10.2003'
```

```
mysql> SELECT STR_TO_DATE('10.31.2003',GET_FORMAT(DATE,'USA'));
-> '2003-10-31'
```

- **HOUR(*time*)**

Returns the hour for *time*. The range of the return value is 0 to 23 for time-of-day values. However, the range of **TIME** values actually is much larger, so **HOUR** can return values greater than 23.

```
mysql> SELECT HOUR('10:05:03');
-> 10
mysql> SELECT HOUR('272:59:59');
-> 272
```

- **LAST_DAY(*date*)**

Takes a date or datetime value and returns the corresponding value for the last day of the month. Returns **NULL** if the argument is invalid.

```
mysql> SELECT LAST_DAY('2003-02-05');
-> '2003-02-28'
mysql> SELECT LAST_DAY('2004-02-05');
-> '2004-02-29'
mysql> SELECT LAST_DAY('2004-01-01 01:01:01');
-> '2004-01-31'
mysql> SELECT LAST_DAY('2003-03-32');
-> NULL
```

- **LOCALTIME, LOCALTIME()**

LOCALTIME and **LOCALTIME()** are synonyms for **NOW()**.

- **LOCALTIMESTAMP, LOCALTIMESTAMP()**

LOCALTIMESTAMP and **LOCALTIMESTAMP()** are synonyms for **NOW()**.

- **MAKEDATE(*year*,*dayofyear*)**

Returns a date, given year and day-of-year values. *dayofyear* must be greater than 0 or the result is **NULL**.

```
mysql> SELECT MAKEDATE(2001,31), MAKEDATE(2001,32);
-> '2001-01-31', '2001-02-01'
mysql> SELECT MAKEDATE(2001,365), MAKEDATE(2004,365);
-> '2001-12-31', '2004-12-30'
mysql> SELECT MAKEDATE(2001,0);
-> NULL
```

- **MAKETIME(*hour*,*minute*,*second*)**

Returns a time value calculated from the *hour*, *minute*, and *second* arguments.

```
mysql> SELECT MAKETIME(12,15,30);
-> '12:15:30'
```

- **MICROSECOND(*expr*)**

Returns the microseconds from the time or datetime expression *expr* as a number in the range from 0 to 999999.

```
mysql> SELECT MICROSECOND('12:00:00.123456');
-> 123456
mysql> SELECT MICROSECOND('1997-12-31 23:59:59.000010');
-> 10
```

- **MINUTE(*time*)**

Returns the minute for *time*, in the range 0 to 59.

```
mysql> SELECT MINUTE('98-02-03 10:05:03');
-> 5
```

- **MONTH(*date*)**

Returns the month for *date*, in the range 0 to 12.

```
mysql> SELECT MONTH('1998-02-03');
-> 2
```

- **MONTHNAME(*date*)**

Returns the full name of the month for *date*. As of MySQL 5.1.12, the language used for the name is controlled by the value of the `lc_time_names` system variable (Section 5.10.9, “MySQL Server Locale Support”).

```
mysql> SELECT MONTHNAME('1998-02-05');
-> 'February'
```

- **NOW()**

Returns the current date and time as a value in 'YYYY-MM-DD HH:MM:SS' or YYYYMMDDHHMMSS format, depending on whether the function is used in a string or numeric context. The value is expressed in the current time zone.

```
mysql> SELECT NOW();
-> '1997-12-15 23:50:26'
mysql> SELECT NOW() + 0;
-> 19971215235026
```

NOW() returns a constant time that indicates the time at which the statement began to execute. (Within a stored routine or trigger, **NOW()** returns the time at which the routine or triggering statement began to execute.) This differs from the behavior for **SYS-DATE()**, which returns the exact time at which it executes.

```
mysql> SELECT NOW(), SLEEP(2), NOW();
+-----+-----+-----+
| NOW()          | SLEEP(2) | NOW()          |
+-----+-----+-----+
| 2006-04-12 13:47:36 |          0 | 2006-04-12 13:47:36 |
+-----+-----+-----+

mysql> SELECT SYSDATE(), SLEEP(2), SYSDATE();
+-----+-----+-----+
| SYSDATE()      | SLEEP(2) | SYSDATE()      |
+-----+-----+-----+
| 2006-04-12 13:47:44 |          0 | 2006-04-12 13:47:46 |
+-----+-----+-----+
```

See the description for **SYS-DATE()** for additional information about the differences between the two functions.

- **PERIOD_ADD(*P*, *N*)**

Adds *N* months to period *P* (in the format **YYMM** or **YYYYMM**). Returns a value in the format **YYYYMM**. Note that the period argument *P* is *not* a date value.

```
mysql> SELECT PERIOD_ADD(9801,2);
-> 199803
```

- **PERIOD_DIFF(*P1*, *P2*)**

Returns the number of months between periods *P1* and *P2*. *P1* and *P2* should be in the format **YYMM** or **YYYYMM**. Note that the period arguments *P1* and *P2* are *not* date values.

```
mysql> SELECT PERIOD_DIFF(9802,199703);
-> 11
```

- **QUARTER(*date*)**

Returns the quarter of the year for *date*, in the range 1 to 4.

```
mysql> SELECT QUARTER('98-04-01');
-> 2
```

- `SECOND(time)`

Returns the second for *time*, in the range 0 to 59.

```
mysql> SELECT SECOND('10:05:03');
-> 3
```

- `SEC_TO_TIME(seconds)`

Returns the *seconds* argument, converted to hours, minutes, and seconds, as a `TIME` value. The range of the result is constrained to that of the `TIME` data type. A warning occurs if the argument corresponds to a value outside that range.

```
mysql> SELECT SEC_TO_TIME(2378);
-> '00:39:38'
mysql> SELECT SEC_TO_TIME(2378) + 0;
-> 3938
```

- `STR_TO_DATE(str, format)`

This is the inverse of the `DATE_FORMAT()` function. It takes a string *str* and a format string *format*. `STR_TO_DATE()` returns a `DATETIME` value if the format string contains both date and time parts, or a `DATE` or `TIME` value if the string contains only date or time parts.

The date, time, or datetime values contained in *str* should be given in the format indicated by *format*. For the specifiers that can be used in *format*, see the `DATE_FORMAT()` function description. If *str* contains an illegal date, time, or datetime value, `STR_TO_DATE()` returns `NULL`. An illegal value also produces a warning.

Range checking on the parts of date values is as described in [Section 10.3.1, “The DATETIME, DATE, and TIMESTAMP Types”](#). This means, for example, that “zero” dates or dates with part values of 0 are allowed unless the SQL mode is set to disallow such values.

```
mysql> SELECT STR_TO_DATE('00/00/0000', '%m/%d/%Y');
-> '0000-00-00'
mysql> SELECT STR_TO_DATE('04/31/2004', '%m/%d/%Y');
-> '2004-04-31'
```

Note

You cannot use format `"%X%V"` to convert a year-week string to a date because the combination of a year and week does not uniquely identify a year and month if the week crosses a month boundary. To convert a year-week to a date, then you should also specify the weekday:

```
mysql> SELECT STR_TO_DATE('200442 Monday', '%X%V %W');
-> '2004-10-18'
```

- `SUBDATE(date, INTERVAL expr unit), SUBDATE(expr, days)`

When invoked with the `INTERVAL` form of the second argument, `SUBDATE()` is a synonym for `DATE_SUB()`. For information on the `INTERVAL unit` argument, see the discussion for `DATE_ADD()`.

```
mysql> SELECT DATE_SUB('1998-01-02', INTERVAL 31 DAY);
-> '1997-12-02'
mysql> SELECT SUBDATE('1998-01-02', INTERVAL 31 DAY);
-> '1997-12-02'
```

The second form allows the use of an integer value for *days*. In such cases, it is interpreted as the number of days to be subtracted from the date or datetime expression *expr*.

```
mysql> SELECT SUBDATE('1998-01-02 12:00:00', 31);
-> '1997-12-02 12:00:00'
```

- `SUBTIME(expr1, expr2)`

`SUBTIME()` returns *expr1* – *expr2* expressed as a value in the same format as *expr1*. *expr1* is a time or datetime expression, and *expr2* is a time expression.

```
mysql> SELECT SUBTIME('1997-12-31 23:59:59.999999', '1 1:1:1.000002');
```

```
mysql> -> '1997-12-30 22:58:58.999997'
mysql> SELECT SUBTIME('01:00:00.999999', '02:00:00.999998');
mysql> -> '-00:59:59.999999'
```

- **`SYSDATE()`**

Returns the current date and time as a value in 'YYYY-MM-DD HH:MM:SS' or YYYYMMDDHHMMSS format, depending on whether the function is used in a string or numeric context.

`SYSDATE()` returns the time at which it executes. This differs from the behavior for **`NOW()`**, which returns a constant time that indicates the time at which the statement began to execute. (Within a stored routine or trigger, **`NOW()`** returns the time at which the routine or triggering statement began to execute.)

```
mysql> SELECT NOW(), SLEEP(2), NOW();
+-----+-----+-----+
| NOW() | SLEEP(2) | NOW() |
+-----+-----+-----+
| 2006-04-12 13:47:36 | 0 | 2006-04-12 13:47:36 |
+-----+-----+-----+

mysql> SELECT SYSDATE(), SLEEP(2), SYSDATE();
+-----+-----+-----+
| SYSDATE() | SLEEP(2) | SYSDATE() |
+-----+-----+-----+
| 2006-04-12 13:47:44 | 0 | 2006-04-12 13:47:46 |
+-----+-----+-----+
```

In addition, the **`SET TIMESTAMP`** statement affects the value returned by **`NOW()`** but not by **`SYSDATE()`**. This means that timestamp settings in the binary log have no effect on invocations of **`SYSDATE()`**.

Because **`SYSDATE()`** can return different values even within the same statement, and is not affected by **`SET TIMESTAMP`**, it is non-deterministic and therefore unsafe for replication if statement-based binary logging is used. If that is a problem, you can use row-based logging, or start the server with the **`--sysdate-is-now`** option to cause **`SYSDATE()`** to be an alias for **`NOW()`**. The non-deterministic nature of **`SYSDATE()`** also means that indexes cannot be used for evaluating expressions that refer to it.

- **`TIME(expr)`**

Extracts the time part of the time or datetime expression *expr* and returns it as a string.

```
mysql> SELECT TIME('2003-12-31 01:02:03');
mysql> -> '01:02:03'
mysql> SELECT TIME('2003-12-31 01:02:03.000123');
mysql> -> '01:02:03.000123'
```

- **`TIMEDIFF(expr1,expr2)`**

`TIMEDIFF()` returns *expr1* – *expr2* expressed as a time value. *expr1* and *expr2* are time or date-and-time expressions, but both must be of the same type.

```
mysql> SELECT TIMEDIFF('2000:01:01 00:00:00',
mysql> -> '2000:01:01 00:00:00.000001');
mysql> -> '-00:00:00.000001'
mysql> SELECT TIMEDIFF('1997-12-31 23:59:59.000001',
mysql> -> '1997-12-30 01:01:01.000002');
mysql> -> '46:58:57.999999'
```

- **`TIMESTAMP(expr)`, `TIMESTAMP(expr1,expr2)`**

With a single argument, this function returns the date or datetime expression *expr* as a datetime value. With two arguments, it adds the time expression *expr2* to the date or datetime expression *expr1* and returns the result as a datetime value.

```
mysql> SELECT TIMESTAMP('2003-12-31');
mysql> -> '2003-12-31 00:00:00'
mysql> SELECT TIMESTAMP('2003-12-31 12:00:00','12:00:00');
mysql> -> '2004-01-01 00:00:00'
```

- **`TIMESTAMPADD(unit,interval,datetime_expr)`**

Adds the integer expression *interval* to the date or datetime expression *datetime_expr*. The unit for *interval* is given by the *unit* argument, which should be one of the following values: **`FRAC_SECOND`**, **`SECOND`**, **`MINUTE`**, **`HOURL`**, **`DAY`**, **`WEEK`**,

, `QUARTER`, or `YEAR`.

The *unit* value may be specified using one of keywords as shown, or with a prefix of `SQL_TSI_`. For example, `DAY` and `SQL_TSI_DAY` both are legal.

```
mysql> SELECT TIMESTAMPADD(MINUTE,1,'2003-01-02');
-> '2003-01-02 00:01:00'
mysql> SELECT TIMESTAMPADD(WEEK,1,'2003-01-02');
-> '2003-01-09'
```

- `TIMESTAMPDIFF(unit,datetime_expr1,datetime_expr2)`

Returns the integer difference between the date or datetime expressions *datetime_expr1* and *datetime_expr2*. The unit for the result is given by the *unit* argument. The legal values for *unit* are the same as those listed in the description of the `TIMESTAMPADD()` function.

```
mysql> SELECT TIMESTAMPDIFF(MONTH,'2003-02-01','2003-05-01');
-> 3
mysql> SELECT TIMESTAMPDIFF(YEAR,'2002-05-01','2001-01-01');
-> -1
```

- `TIME_FORMAT(time,format)`

This is used like the `DATE_FORMAT()` function, but the *format* string may contain format specifiers only for hours, minutes, and seconds. Other specifiers produce a `NULL` value or `0`.

If the *time* value contains an hour part that is greater than 23, the `%H` and `%k` hour format specifiers produce a value larger than the usual range of 0..23. The other hour format specifiers produce the hour value modulo 12.

```
mysql> SELECT TIME_FORMAT('100:00:00','%H %k %h %I %l');
-> '100 100 04 04 4'
```

- `TIME_TO_SEC(time)`

Returns the *time* argument, converted to seconds.

```
mysql> SELECT TIME_TO_SEC('22:23:00');
-> 80580
mysql> SELECT TIME_TO_SEC('00:39:38');
-> 2378
```

- `TO_DAYS(date)`

Given a date *date*, returns a day number (the number of days since year 0).

```
mysql> SELECT TO_DAYS(950501);
-> 728779
mysql> SELECT TO_DAYS('1997-10-07');
-> 729669
```

`TO_DAYS()` is not intended for use with values that precede the advent of the Gregorian calendar (1582), because it does not take into account the days that were lost when the calendar was changed. For dates before 1582 (and possibly a later year in other locales), results from this function are not reliable. See [Section 11.7, “What Calendar Is Used By MySQL?”](#), for details.

Remember that MySQL converts two-digit year values in dates to four-digit form using the rules in [Section 10.3, “Date and Time Types”](#). For example, `'1997-10-07'` and `'97-10-07'` are seen as identical dates:

```
mysql> SELECT TO_DAYS('1997-10-07'), TO_DAYS('97-10-07');
-> 729669, 729669
```

- `UNIX_TIMESTAMP()`, `UNIX_TIMESTAMP(date)`

If called with no argument, returns a Unix timestamp (seconds since `'1970-01-01 00:00:00'` UTC) as an unsigned integer. If `UNIX_TIMESTAMP()` is called with a *date* argument, it returns the value of the argument as seconds since `'1970-01-01 00:00:00'` UTC. *date* may be a `DATE` string, a `DATETIME` string, a `TIMESTAMP`, or a number in the format `YYMMDD` or `YYYYMMDD`. The server interprets *date* as a value in the current time zone and converts it to an internal value in UTC. Clients can set their time zone as described in [Section 5.10.8, “MySQL Server Time Zone Support”](#).

```
mysql> SELECT UNIX_TIMESTAMP();
-> 882226357
mysql> SELECT UNIX_TIMESTAMP('1997-10-04 22:23:00');
-> 875996580
```

When `UNIX_TIMESTAMP` is used on a `TIMESTAMP` column, the function returns the internal timestamp value directly, with no implicit “string-to-Unix-timestamp” conversion. If you pass an out-of-range date to `UNIX_TIMESTAMP()`, it returns `0`.

Note: If you use `UNIX_TIMESTAMP()` and `FROM_UNIXTIME()` to convert between `TIMESTAMP` values and Unix timestamp values, the conversion is lossy because the mapping is not one-to-one in both directions. For example, due to conventions for local time zone changes, it is possible for two `UNIX_TIMESTAMP()` to map two `TIMESTAMP` values to the same Unix timestamp value. `FROM_UNIXTIME()` will map that value back to only one of the original `TIMESTAMP` values. Here is an example, using `TIMESTAMP` values in the CET time zone:

```
mysql> SELECT UNIX_TIMESTAMP('2005-03-27 03:00:00');
+-----+
| UNIX_TIMESTAMP('2005-03-27 03:00:00') |
+-----+
| 1111885200 |
+-----+
mysql> SELECT UNIX_TIMESTAMP('2005-03-27 02:00:00');
+-----+
| UNIX_TIMESTAMP('2005-03-27 02:00:00') |
+-----+
| 1111885200 |
+-----+
mysql> SELECT FROM_UNIXTIME(1111885200);
+-----+
| FROM_UNIXTIME(1111885200) |
+-----+
| 2005-03-27 03:00:00 |
+-----+
```

If you want to subtract `UNIX_TIMESTAMP()` columns, you might want to cast the result to signed integers. See [Section 11.9, “Cast Functions and Operators”](#).

- `UTC_DATE, UTC_DATE()`

Returns the current UTC date as a value in 'YYYY-MM-DD' or YYYYMMDD format, depending on whether the function is used in a string or numeric context.

```
mysql> SELECT UTC_DATE(), UTC_DATE() + 0;
-> '2003-08-14', 20030814
```

- `UTC_TIME, UTC_TIME()`

Returns the current UTC time as a value in 'HH:MM:SS' or HHMMSS format, depending on whether the function is used in a string or numeric context.

```
mysql> SELECT UTC_TIME(), UTC_TIME() + 0;
-> '18:07:53', 180753
```

- `UTC_TIMESTAMP, UTC_TIMESTAMP()`

Returns the current UTC date and time as a value in 'YYYY-MM-DD HH:MM:SS' or YYYYMMDDHHMMSS format, depending on whether the function is used in a string or numeric context.

```
mysql> SELECT UTC_TIMESTAMP(), UTC_TIMESTAMP() + 0;
-> '2003-08-14 18:08:04', 20030814180804
```

- `WEEK(date[,mode])`

This function returns the week number for *date*. The two-argument form of `WEEK()` allows you to specify whether the week starts on Sunday or Monday and whether the return value should be in the range from `0` to `53` or from `1` to `53`. If the *mode* argument is omitted, the value of the `default_week_format` system variable is used. See [Section 5.2.3, “System Variables”](#).

The following table describes how the *mode* argument works.

	First day		

Mode	of week	Range	Week 1 is the first week ...
0	Sunday	0-53	with a Sunday in this year
1	Monday	0-53	with more than 3 days this year
2	Sunday	1-53	with a Sunday in this year
3	Monday	1-53	with more than 3 days this year
4	Sunday	0-53	with more than 3 days this year
5	Monday	0-53	with a Monday in this year
6	Sunday	1-53	with more than 3 days this year
7	Monday	1-53	with a Monday in this year

```
mysql> SELECT WEEK('1998-02-20');
-> 7
mysql> SELECT WEEK('1998-02-20',0);
-> 7
mysql> SELECT WEEK('1998-02-20',1);
-> 8
mysql> SELECT WEEK('1998-12-31',1);
-> 53
```

Note that if a date falls in the last week of the previous year, MySQL returns 0 if you do not use 2, 3, 6, or 7 as the optional *mode* argument:

```
mysql> SELECT YEAR('2000-01-01'), WEEK('2000-01-01',0);
-> 2000, 0
```

One might argue that MySQL should return 52 for the `WEEK()` function, because the given date actually occurs in the 52nd week of 1999. We decided to return 0 instead because we want the function to return “the week number in the given year.” This makes use of the `WEEK()` function reliable when combined with other functions that extract a date part from a date.

If you would prefer the result to be evaluated with respect to the year that contains the first day of the week for the given date, use 0, 2, 5, or 7 as the optional *mode* argument.

```
mysql> SELECT WEEK('2000-01-01',2);
-> 52
```

Alternatively, use the `YEARWEEK()` function:

```
mysql> SELECT YEARWEEK('2000-01-01');
-> 199952
mysql> SELECT MID(YEARWEEK('2000-01-01'),5,2);
-> '52'
```

- `WEEKDAY(date)`

Returns the weekday index for *date* (0 = Monday, 1 = Tuesday, ... 6 = Sunday).

```
mysql> SELECT WEEKDAY('1998-02-03 22:23:00');
-> 1
mysql> SELECT WEEKDAY('1997-11-05');
-> 2
```

- `WEEKOFYEAR(date)`

Returns the calendar week of the date as a number in the range from 1 to 53. `WEEKOFYEAR()` is a compatibility function that is equivalent to `WEEK(date,3)`.

```
mysql> SELECT WEEKOFYEAR('1998-02-20');
-> 8
```

- `YEAR(date)`

Returns the year for *date*, in the range 1000 to 9999, or 0 for the “zero” date.

```
mysql> SELECT YEAR('98-02-03');
-> 1998
```

- **YEARWEEK(*date*), YEARWEEK(*date*,*mode*)**

Returns year and week for a date. The *mode* argument works exactly like the *mode* argument to **WEEK()**. The year in the result may be different from the year in the date argument for the first and the last week of the year.

```
mysql> SELECT YEARWEEK('1987-01-01');
-> 198653
```

Note that the week number is different from what the **WEEK()** function would return (0) for optional arguments 0 or 1, as **WEEK()** then returns the week in the context of the given year.

11.7. What Calendar Is Used By MySQL?

MySQL uses what is known as a *proleptic Gregorian calendar*.

Every country that has switched from the Julian to the Gregorian calendar has had to discard at least ten days during the switch. To see how this works, consider the month of October 1582, when the first Julian-to-Gregorian switch occurred:

Monday	Tuesday	Wednesday	Thursday	Friday	Saturday	Sunday
1	2	3	4	15	16	17
18	19	20	21	22	23	24
25	26	27	28	29	30	31

There are no dates between October 4 and October 15. This discontinuity is called the *cutover*. Any dates before the cutover are Julian, and any dates following the cutover are Gregorian. Dates during a cutover are non-existent.

A calendar applied to dates when it wasn't actually in use is called *proleptic*. Thus, if we assume there was never a cutover and Gregorian rules always rule, we have a proleptic Gregorian calendar. This is what is used by MySQL, as is required by standard SQL. For this reason, dates prior to the cutover stored as MySQL **DATE** or **DATETIME** values must be adjusted to compensate for the difference. It is important to realize that the cutover did not occur at the same time in all countries, and that the later it happened, the more days were lost. For example, in Great Britain, it took place in 1752, when Wednesday September 2 was followed by Thursday September 14. Russia remained on the Julian calendar until 1918, losing 13 days in the process, and what is popularly referred to as its “October Revolution” occurred in November according to the Gregorian calendar.

11.8. Full-Text Search Functions

```
MATCH (col1,col2,...) AGAINST (expr [search_modifier])
search_modifier:
{
  IN BOOLEAN MODE
  | IN NATURAL LANGUAGE MODE
  | IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION
  | WITH QUERY EXPANSION
}
```

MySQL has support for full-text indexing and searching:

- A full-text index in MySQL is an index of type **FULLTEXT**.
- Full-text indexes can be used only with **MyISAM** tables, and can be created only for **CHAR**, **VARCHAR**, or **TEXT** columns.
- A **FULLTEXT** index definition can be given in the **CREATE TABLE** statement when a table is created, or added later using **ALTER TABLE** or **CREATE INDEX**.

- For large datasets, it is much faster to load your data into a table that has no `FULLTEXT` index and then create the index after that, than to load data into a table that has an existing `FULLTEXT` index.

Full-text searching is performed using `MATCH() ... AGAINST` syntax. `MATCH()` takes a comma-separated list that names the columns to be searched. `AGAINST` takes a string to search for, and an optional modifier that indicates what type of search to perform. The search string must be a literal string, not a variable or a column name. There are three types of full-text searches:

- A boolean search interprets the search string using the rules of a special query language. The string contains the words to search for. It can also contain operators that specify requirements such that a word must be present or absent in matching rows, or that it should be weighted higher or lower than usual. Common words such as “some” or “then” are stopwords and do not match if present in the search string. The `IN BOOLEAN MODE` modifier specifies a boolean search. For more information, see [Section 11.8.1, “Boolean Full-Text Searches”](#).
- A natural language search interprets the search string as a phrase in natural human language (a phrase in free text). There are no special operators. The stopword list applies. In addition, words that are present in more than 50% of the rows are considered common and do not match. Full-text searches are natural language searches if the `IN NATURAL LANGUAGE MODE` modifier is given or if no modifier is given.
- A query expansion search is a modification of a natural language search. The search string is used to perform a natural language search. Then words from the most relevant rows returned by the search are added to the search string and the search is done again. The query returns the rows from the second search. The `IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION` or `WITH QUERY EXPANSION` modifier specifies a query expansion search. For more information, see [Section 11.8.2, “Full-Text Searches with Query Expansion”](#).

The `IN NATURAL LANGUAGE MODE` and `IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION` modifiers were added in MySQL 5.1.7.

Constraints on full-text searching are listed in [Section 11.8.4, “Full-Text Restrictions”](#).

```
mysql> CREATE TABLE articles (
->   id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
->   title VARCHAR(200),
->   body TEXT,
->   FULLTEXT (title,body)
-> );
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO articles (title,body) VALUES
-> ('MySQL Tutorial','DBMS stands for DataBase ...'),
-> ('How To Use MySQL Well','After you went through a ...'),
-> ('Optimizing MySQL','In this tutorial we will show ...'),
-> ('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),
-> ('MySQL vs. YourSQL','In the following database comparison ...'),
-> ('MySQL Security','When configured properly, MySQL ...');
Query OK, 6 rows affected (0.00 sec)
Records: 6  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM articles
-> WHERE MATCH (title,body)
-> AGAINST ('database' IN NATURAL LANGUAGE MODE);
+----+-----+-----+
| id | title                | body                |
+----+-----+-----+
| 5  | MySQL vs. YourSQL    | In the following database comparison ... |
| 1  | MySQL Tutorial       | DBMS stands for DataBase ... |
+----+-----+-----+
2 rows in set (0.00 sec)
```

The `MATCH()` function performs a natural language search for a string against a *text collection*. A collection is a set of one or more columns included in a `FULLTEXT` index. The search string is given as the argument to `AGAINST()`. For each row in the table, `MATCH()` returns a relevance value; that is, a similarity measure between the search string and the text in that row in the columns named in the `MATCH()` list.

By default, the search is performed in case-insensitive fashion. However, you can perform a case-sensitive full-text search by using a binary collation for the indexed columns. For example, a column that uses the `latin1` character set of can be assigned a collation of `latin1_bin` to make it case sensitive for full-text searches.

When `MATCH()` is used in a `WHERE` clause, as in the example shown earlier, the rows returned are automatically sorted with the highest relevance first. Relevance values are non-negative floating-point numbers. Zero relevance means no similarity. Relevance is

computed based on the number of words in the row, the number of unique words in that row, the total number of words in the collection, and the number of documents (rows) that contain a particular word.

To simply count matches, you could use a query like this:

```
mysql> SELECT COUNT(*) FROM articles
-> WHERE MATCH (title,body)
-> AGAINST ('database' IN NATURAL LANGUAGE MODE);
+-----+
| COUNT(*) |
+-----+
|          2 |
+-----+
1 row in set (0.00 sec)
```

However, you might find it quicker to rewrite the query as follows:

```
mysql> SELECT
-> COUNT(IF(MATCH (title,body) AGAINST ('database' IN NATURAL LANGUAGE MODE), 1, NULL))
-> AS count
-> FROM articles;
+-----+
| count |
+-----+
|          2 |
+-----+
1 row in set (0.03 sec)
```

The first query sorts the results by relevance whereas the second does not. However, the second query performs a full table scan and the first does not. The first may be faster if the search matches few rows; otherwise, the second may be faster because it would read many rows anyway.

For natural-language full-text searches, it is a requirement that the columns named in the `MATCH()` function be the same columns included in some `FULLTEXT` index in your table. For the preceding query, note that the columns named in the `MATCH()` function (`title` and `body`) are the same as those named in the definition of the `article` table's `FULLTEXT` index. If you wanted to search the `title` or `body` separately, you would need to create separate `FULLTEXT` indexes for each column.

It is also possible to perform a boolean search or a search with query expansion. These search types are described in [Section 11.8.1, “Boolean Full-Text Searches”](#), and [Section 11.8.2, “Full-Text Searches with Query Expansion”](#).

A full-text search that uses an index can name columns only from a single table in the `MATCH()` clause because an index cannot span multiple tables. A boolean search can be done in the absence of an index (albeit more slowly), in which case it is possible to name columns from multiple tables.

The preceding example is a basic illustration that shows how to use the `MATCH()` function where rows are returned in order of decreasing relevance. The next example shows how to retrieve the relevance values explicitly. Returned rows are not ordered because the `SELECT` statement includes neither `WHERE` nor `ORDER BY` clauses:

```
mysql> SELECT id, MATCH (title,body)
-> AGAINST ('Tutorial' IN NATURAL LANGUAGE MODE) AS score
-> FROM articles;
+-----+
| id | score |
+-----+
| 1 | 0.65545833110809 |
| 2 | 0 |
| 3 | 0.66266459226608 |
| 4 | 0 |
| 5 | 0 |
| 6 | 0 |
+-----+
6 rows in set (0.00 sec)
```

The following example is more complex. The query returns the relevance values and it also sorts the rows in order of decreasing relevance. To achieve this result, you should specify `MATCH()` twice: once in the `SELECT` list and once in the `WHERE` clause. This causes no additional overhead, because the MySQL optimizer notices that the two `MATCH()` calls are identical and invokes the full-text search code only once.

```
mysql> SELECT id, body, MATCH (title,body) AGAINST
-> ('Security implications of running MySQL as root'
-> IN NATURAL LANGUAGE MODE) AS score
-> FROM articles WHERE MATCH (title,body) AGAINST
-> ('Security implications of running MySQL as root'
-> IN NATURAL LANGUAGE MODE);
+-----+-----+-----+
| id | body | MATCH (title,body) AGAINST
```

id	body	score
4	1. Never run mysqld as root. 2. ...	1.5219271183014
6	When configured properly, MySQL ...	1.3114095926285

2 rows in set (0.00 sec)

The MySQL **FULLTEXT** implementation regards any sequence of true word characters (letters, digits, and underscores) as a word. That sequence may also contain apostrophes (''), but not more than one in a row. This means that `aaa'bbb` is regarded as one word, but `aaa'bbb` is regarded as two words. Apostrophes at the beginning or the end of a word are stripped by the **FULLTEXT** parser; `'aaa'bbb` would be parsed as `aaa'bbb`.

The **FULLTEXT** parser determines where words start and end by looking for certain delimiter characters; for example, ' ' (space), ',', (comma), and '.' (period). If words are not separated by delimiters (as in, for example, Chinese), the **FULLTEXT** parser cannot determine where a word begins or ends. To be able to add words or other indexed terms in such languages to a **FULLTEXT** index, you must preprocess them so that they are separated by some arbitrary delimiter such as ''.

In MySQL 5.1, it is possible to write a plugin that replaces the built-in full-text parser. For details, see [Section 28.2, “The MySQL Plugin Interface”](#). For example parser plugin source code, see the [plugin/fulltext](#) directory of a MySQL source distribution.

Some words are ignored in full-text searches:

- Any word that is too short is ignored. The default minimum length of words that are found by full-text searches is four characters.
- Words in the stopword list are ignored. A stopword is a word such as “the” or “some” that is so common that it is considered to have zero semantic value. There is a built-in stopword list, but it can be overwritten by a user-defined list.

The default stopword list is given in [Section 11.8.3, “Full-Text Stopwords”](#). The default minimum word length and stopword list can be changed as described in [Section 11.8.5, “Fine-Tuning MySQL Full-Text Search”](#).

Every correct word in the collection and in the query is weighted according to its significance in the collection or query. Consequently, a word that is present in many documents has a lower weight (and may even have a zero weight), because it has lower semantic value in this particular collection. Conversely, if the word is rare, it receives a higher weight. The weights of the words are combined to compute the relevance of the row.

Such a technique works best with large collections (in fact, it was carefully tuned this way). For very small tables, word distribution does not adequately reflect their semantic value, and this model may sometimes produce bizarre results. For example, although the word “MySQL” is present in every row of the `articles` table shown earlier, a search for the word produces no results:

```
mysql> SELECT * FROM articles
-> WHERE MATCH (title,body)
-> AGAINST ('MySQL' IN NATURAL LANGUAGE MODE);
Empty set (0.00 sec)
```

The search result is empty because the word “MySQL” is present in at least 50% of the rows. As such, it is effectively treated as a stopword. For large datasets, this is the most desirable behavior: A natural language query should not return every second row from a 1GB table. For small datasets, it may be less desirable.

A word that matches half of the rows in a table is less likely to locate relevant documents. In fact, it most likely finds plenty of irrelevant documents. We all know this happens far too often when we are trying to find something on the Internet with a search engine. It is with this reasoning that rows containing the word are assigned a low semantic value for *the particular dataset in which they occur*. A given word may exceed the 50% threshold in one dataset but not another.

The 50% threshold has a significant implication when you first try full-text searching to see how it works: If you create a table and insert only one or two rows of text into it, every word in the text occurs in at least 50% of the rows. As a result, no search returns any results. Be sure to insert at least three rows, and preferably many more. Users who need to bypass the 50% limitation can use the boolean search mode; see [Section 11.8.1, “Boolean Full-Text Searches”](#).

11.8.1. Boolean Full-Text Searches

MySQL can perform boolean full-text searches using the `IN BOOLEAN MODE` modifier:

```
mysql> SELECT * FROM articles WHERE MATCH (title,body)
-> AGAINST ('+MySQL -YourSQL' IN BOOLEAN MODE);
+-----+-----+
| id | title | body |
+-----+-----+
+-----+-----+
+-----+-----+
```

3	Optimizing MySQL	In this tutorial we will show ...
4	1001 MySQL Tricks	1. Never run mysqld as root. 2. ...
6	MySQL Security	When configured properly, MySQL ...

The `+` and `-` operators indicate that a word is required to be present or absent, respectively, for a match to occur. Thus, this query retrieves all the rows that contain the word “MySQL” but that do *not* contain the word “YourSQL”.

Boolean full-text searches have these characteristics:

- They do not use the 50% threshold.
- They do not automatically sort rows in order of decreasing relevance. You can see this from the preceding query result: The row with the highest relevance is the one that contains “MySQL” twice, but it is listed last, not first.
- They can work even without a `FULLTEXT` index, although a search executed in this fashion would be quite slow.
- The minimum and maximum word length full-text parameters apply.
- The stopword list applies.

The boolean full-text search capability supports the following operators:

- `+`

A leading plus sign indicates that this word *must* be present in each row that is returned.

- `-`

A leading minus sign indicates that this word must *not* be present in any of the rows that are returned.

Note: The `-` operator acts only to exclude rows that are otherwise matched by other search terms. Thus, a boolean-mode search that contains only terms preceded by `-` returns an empty result. It does not return “all rows except those containing any of the excluded terms.”

- (no operator)

By default (when neither `+` nor `-` is specified) the word is optional, but the rows that contain it are rated higher. This mimics the behavior of `MATCH() ... AGAINST()` without the `IN BOOLEAN MODE` modifier.

- `>` `<`

These two operators are used to change a word's contribution to the relevance value that is assigned to a row. The `>` operator increases the contribution and the `<` operator decreases it. See the example following this list.

- `( )`

Parentheses group words into subexpressions. Parenthesized groups can be nested.

- `~`

A leading tilde acts as a negation operator, causing the word's contribution to the row's relevance to be negative. This is useful for marking “noise” words. A row containing such a word is rated lower than others, but is not excluded altogether, as it would be with the `-` operator.

- `*`

The asterisk serves as the truncation (or wildcard) operator. Unlike the other operators, it should be *appended* to the word to be affected. Words match if they begin with the word preceding the `*` operator.

If a stopword or too-short word is specified with the truncation operator, it will not be stripped from a boolean query. For example, a search for `'+word +stopword*'` will likely return fewer rows than a search for `'+word +stopword'` because the former query remains as is and requires `stopword*` to be present in a document. The latter query is transformed to `+word`.

- `"`

A phrase that is enclosed within double quote (`"`) characters matches only rows that contain the phrase *literally, as it was typed*. The full-text engine splits the phrase into words, performs a search in the `FULLTEXT` index for the words. Non-word characters need not be matched exactly: Phrase searching requires only that matches contain exactly the same words as the phrase and in the same order. For example, `"test phrase"` matches `"test, phrase"`.

If the phrase contains no words that are in the index, the result is empty. For example, if all words are either stopwords or shorter than the minimum length of indexed words, the result is empty.

The following examples demonstrate some search strings that use boolean full-text operators:

- `'apple banana'`

Find rows that contain at least one of the two words.

- `'+apple +juice'`

Find rows that contain both words.

- `'+apple macintosh'`

Find rows that contain the word “apple”, but rank rows higher if they also contain “macintosh”.

- `'+apple -macintosh'`

Find rows that contain the word “apple” but not “macintosh”.

- `'+apple ~macintosh'`

Find rows that contain the word “apple”, but if the row also contains the word “macintosh”, rate it lower than if row does not. This is “softer” than a search for `'+apple -macintosh'`, for which the presence of “macintosh” causes the row not to be returned at all.

- `'+apple +(>turnover <strudel)'`

Find rows that contain the words “apple” and “turnover”, or “apple” and “strudel” (in any order), but rank “apple turnover” higher than “apple strudel”.

- `'apple*'`

Find rows that contain words such as “apple”, “apples”, “applesauce”, or “applet”.

- `'"some words"'`

Find rows that contain the exact phrase “some words” (for example, rows that contain “some words of wisdom” but not “some noise words”). Note that the `"` characters that enclose the phrase are operator characters that delimit the phrase. They are not the quotes that enclose the search string itself.

11.8.2. Full-Text Searches with Query Expansion

Full-text search supports query expansion (and in particular, its variant “blind query expansion”). This is generally useful when a search phrase is too short, which often means that the user is relying on implied knowledge that the full-text search engine lacks. For example, a user searching for “database” may really mean that “MySQL”, “Oracle”, “DB2”, and “RDBMS” all are phrases that should match “databases” and should be returned, too. This is implied knowledge.

Blind query expansion (also known as automatic relevance feedback) is enabled by adding `WITH QUERY EXPANSION` or `IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION` following the search phrase. It works by performing the search twice, where the search phrase for the second search is the original search phrase concatenated with the few most highly relevant documents from the first search. Thus, if one of these documents contains the word “databases” and the word “MySQL”, the second search finds the documents that contain the word “MySQL” even if they do not contain the word “database”. The following example shows this difference:

```
mysql> SELECT * FROM articles
```

```

-> WHERE MATCH (title,body)
-> AGAINST ('database' IN NATURAL LANGUAGE MODE);
+-----+-----+-----+
| id | title | body |
+-----+-----+-----+
| 5 | MySQL vs. YourSQL | In the following database comparison ... |
| 1 | MySQL Tutorial | DBMS stands for DataBase ... |
+-----+-----+-----+
2 rows in set (0.00 sec)

mysql> SELECT * FROM articles
-> WHERE MATCH (title,body)
-> AGAINST ('database' WITH QUERY EXPANSION);
+-----+-----+-----+
| id | title | body |
+-----+-----+-----+
| 1 | MySQL Tutorial | DBMS stands for DataBase ... |
| 5 | MySQL vs. YourSQL | In the following database comparison ... |
| 3 | Optimizing MySQL | In this tutorial we will show ... |
+-----+-----+-----+
3 rows in set (0.00 sec)

```

Another example could be searching for books by Georges Simenon about Maigret, when a user is not sure how to spell “Maigret”. A search for “Megre and the reluctant witnesses” finds only “Maigret and the Reluctant Witnesses” without query expansion. A search with query expansion finds all books with the word “Maigret” on the second pass.

Note

Because blind query expansion tends to increase noise significantly by returning non-relevant documents, it is meaningful to use only when a search phrase is rather short.

11.8.3. Full-Text Stopwords

The following table shows the default list of full-text stopwords.

a's	able	about	above	according

11.8.4. Full-Text Restrictions

- Full-text searches are supported for [MyISAM](#) tables only.

- Full-text searches can be used with most multi-byte character sets. The exception is that for Unicode, the `utf8` character set can be used, but not the `ucs2` character set.
- Ideographic languages such as Chinese and Japanese do not have word delimiters. Therefore, the `FULLTEXT` parser *cannot determine where words begin and end in these and other such languages*. The implications of this and some workarounds for the problem are described in [Section 11.8, “Full-Text Search Functions”](#).
- Although the use of multiple character sets within a single table is supported, all columns in a `FULLTEXT` index must use the same character set and collation.
- The `MATCH()` column list must match exactly the column list in some `FULLTEXT` index definition for the table, unless this `MATCH()` is `IN BOOLEAN MODE`. Boolean-mode searches can be done on non-indexed columns, although they are likely to be slow.
- The argument to `AGAINST()` must be a constant string.

11.8.5. Fine-Tuning MySQL Full-Text Search

MySQL's full-text search capability has few user-tunable parameters. You can exert more control over full-text searching behavior if you have a MySQL source distribution because some changes require source code modifications. See [Section 2.9, “MySQL Installation Using a Source Distribution”](#).

Note that full-text search is carefully tuned for the most effectiveness. Modifying the default behavior in most cases can actually decrease effectiveness. *Do not alter the MySQL sources unless you know what you are doing.*

Most full-text variables described in this section must be set at server startup time. A server restart is required to change them; they cannot be modified while the server is running.

Some variable changes require that you rebuild the `FULLTEXT` indexes in your tables. Instructions for doing this are given at the end of this section.

- The minimum and maximum lengths of words to be indexed are defined by the `ft_min_word_len` and `ft_max_word_len` system variables. (See [Section 5.2.3, “System Variables”](#).) The default minimum value is four characters; the default maximum is version dependent. If you change either value, you must rebuild your `FULLTEXT` indexes. For example, if you want three-character words to be searchable, you can set the `ft_min_word_len` variable by putting the following lines in an option file:

```
[mysqld]
ft_min_word_len=3
```

Then you must restart the server and rebuild your `FULLTEXT` indexes. Note particularly the remarks regarding `myisamchk` in the instructions following this list.

- To override the default stopword list, set the `ft_stopword_file` system variable. (See [Section 5.2.3, “System Variables”](#).) The variable value should be the pathname of the file containing the stopword list, or the empty string to disable stopword filtering. After changing the value of this variable or the contents of the stopword file, restart the server and rebuild your `FULLTEXT` indexes.

The stopword list is free-form. That is, you may use any non-alphanumeric character such as newline, space, or comma to separate stopwords. Exceptions are the underscore character (`'_'`) and a single apostrophe (`' '`) which are treated as part of a word. The character set of the stopword list is the server's default character set; see [Section 9.3.1, “Server Character Set and Collation”](#).

- The 50% threshold for natural language searches is determined by the particular weighting scheme chosen. To disable it, look for the following line in `storage/myisam/ftdefs.h`:

```
#define GWS_IN_USE GWS_PROB
```

Change that line to this:

```
#define GWS_IN_USE GWS_FREQ
```

Then recompile MySQL. There is no need to rebuild the indexes in this case. **Note:** By making this change, you *severely* decrease MySQL's ability to provide adequate relevance values for the `MATCH()` function. If you really need to search for such common words, it would be better to search using `IN BOOLEAN MODE` instead, which does not observe the 50% threshold.

- To change the operators used for boolean full-text searches, set the `ft_boolean_syntax` system variable. This variable can be changed while the server is running, but you must have the `SUPER` privilege to do so. No rebuilding of indexes is necessary in this case. See [Section 5.2.3, “System Variables”](#), which describes the rules governing how to set this variable.
- If you want to change the set of characters that are considered word characters, you can do so in two ways. Suppose that you want to treat the hyphen character ('-') as a word character. Use either of these methods:
 - Modify the MySQL source: In `storage/myisam/ftdefs.h`, see the `true_word_char()` and `misc_word_char()` macros. Add '-' to one of those macros and recompile MySQL.
 - Modify a character set file: This requires no recompilation. The `true_word_char()` macro uses a “character type” table to distinguish letters and numbers from other characters. You can edit the `<ctype><map>` contents in one of the character set XML files to specify that '-' is a “letter.” Then use the given character set for your `FULLTEXT` indexes.

After making the modification, you must rebuild the indexes for each table that contains any `FULLTEXT` indexes.

If you modify full-text variables that affect indexing (`ft_min_word_len`, `ft_max_word_len`, or `ft_stopword_file`), or if you change the stopwords file itself, you must rebuild your `FULLTEXT` indexes after making the changes and restarting the server. To rebuild the indexes in this case, it is sufficient to do a `QUICK` repair operation:

```
mysql> REPAIR TABLE tbl_name QUICK;
```

Each table that contains any `FULLTEXT` index must be repaired as just shown. Otherwise, queries for the table may yield incorrect results, and modifications to the table will cause the server to see the table as corrupt and in need of repair.

Note that if you use `myisamchk` to perform an operation that modifies table indexes (such as repair or analyze), the `FULLTEXT` indexes are rebuilt using the *default* full-text parameter values for minimum word length, maximum word length, and stopwords file unless you specify otherwise. This can result in queries failing.

The problem occurs because these parameters are known only by the server. They are not stored in `MyISAM` index files. To avoid the problem if you have modified the minimum or maximum word length or stopwords file values used by the server, specify the same `ft_min_word_len`, `ft_max_word_len`, and `ft_stopword_file` values to `myisamchk` that you use for `mysqld`. For example, if you have set the minimum word length to 3, you can repair a table with `myisamchk` like this:

```
shell> myisamchk --recover --ft_min_word_len=3 tbl_name.MYI
```

To ensure that `myisamchk` and the server use the same values for full-text parameters, place each one in both the `[mysqld]` and `[myisamchk]` sections of an option file:

```
[mysqld]
ft_min_word_len=3

[myisamchk]
ft_min_word_len=3
```

An alternative to using `myisamchk` is to use the `REPAIR TABLE`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, or `ALTER TABLE` statements. These statements are performed by the server, which knows the proper full-text parameter values to use.

11.9. Cast Functions and Operators

Name	Description
<code>BINARY</code>	Cast a string to a binary string
<code>CAST()</code>	Cast a value as a certain type

- `BINARY`

The `BINARY` operator casts the string following it to a binary string. This is an easy way to force a column comparison to be done byte by byte rather than character by character. This causes the comparison to be case sensitive even if the column isn't defined as `BINARY` or `BLOB`. `BINARY` also causes trailing spaces to be significant.

```
mysql> SELECT 'a' = 'A';
```

```
mysql> -> 1
mysql> SELECT BINARY 'a' = 'A';
mysql> -> 0
mysql> SELECT 'a' = 'a ';
mysql> -> 1
mysql> SELECT BINARY 'a' = 'a ';
mysql> -> 0
```

In a comparison, **BINARY** affects the entire operation; it can be given before either operand with the same result.

BINARY *str* is shorthand for **CAST(str AS BINARY)**.

Note that in some contexts, if you cast an indexed column to **BINARY**, MySQL is not able to use the index efficiently.

- **CAST(expr AS type)**, **CONVERT(expr, type)**, **CONVERT(expr USING transcoding_name)**

The **CAST()** and **CONVERT()** functions take a value of one type and produce a value of another type.

The *type* can be one of the following values:

- **BINARY[(N)]**
- **CHAR[(N)]**
- **DATE**
- **DATETIME**
- **DECIMAL**
- **SIGNED [INTEGER]**
- **TIME**
- **UNSIGNED [INTEGER]**

BINARY produces a string with the **BINARY** data type. See [Section 10.4.2, “The BINARY and VARBINARY Types”](#) for a description of how this affects comparisons. If the optional length *N* is given, **BINARY(N)** causes the cast to use no more than *N* bytes of the argument. Values shorter than *N* bytes are padded with **0x00** bytes to a length of *N*.

CHAR(N) causes the cast to use no more than *N* characters of the argument.

CAST() and **CONVERT(... USING ...)** are standard SQL syntax. The non-**USING** form of **CONVERT()** is ODBC syntax.

CONVERT() with **USING** is used to convert data between different character sets. In MySQL, transcoding names are the same as the corresponding character set names. For example, this statement converts the string **'abc'** in the default character set to the corresponding string in the **utf8** character set:

```
SELECT CONVERT('abc' USING utf8);
```

Normally, you cannot compare a **BLOB** value or other binary string in case-insensitive fashion because binary strings have no character set, and thus no concept of lettercase. To perform a case-insensitive comparison, use the **CONVERT()** function to convert the value to a non-binary string. If the character set of the result has a case-insensitive collation, the **LIKE** operation is not case sensitive:

```
SELECT 'A' LIKE CONVERT(blob_col USING latin1) FROM tbl_name;
```

To use a different character set, substitute its name for **latin1** in the preceding statement. To ensure that a case-insensitive collation is used, specify a **COLLATE** clause following the **CONVERT()** call.

CONVERT() can be used more generally for comparing strings that are represented in different character sets.

The cast functions are useful when you want to create a column with a specific type in a **CREATE ... SELECT** statement:

```
CREATE TABLE new_table SELECT CAST('2000-01-01' AS DATE);
```

The functions also can be useful for sorting [ENUM](#) columns in lexical order. Normally, sorting of [ENUM](#) columns occurs using the internal numeric values. Casting the values to [CHAR](#) results in a lexical sort:

```
SELECT enum_col FROM tbl_name ORDER BY CAST(enum_col AS CHAR);
```

`CAST(str AS BINARY)` is the same thing as `BINARY str`. `CAST(expr AS CHAR)` treats the expression as a string with the default character set.

`CAST()` also changes the result if you use it as part of a more complex expression such as `CONCAT('Date: ', CAST(NOW() AS DATE))`.

You should not use `CAST()` to extract data in different formats but instead use string functions like `LEFT()` or `EXTRACT()`. See [Section 11.6, “Date and Time Functions”](#).

To cast a string to a numeric value in numeric context, you normally do not have to do anything other than to use the string value as though it were a number:

```
mysql> SELECT 1+'1';
-> 2
```

If you use a number in string context, the number automatically is converted to a [BINARY](#) string.

```
mysql> SELECT CONCAT('hello you ',2);
-> 'hello you 2'
```

MySQL supports arithmetic with both signed and unsigned 64-bit values. If you are using numeric operators (such as `+` or `-`) and one of the operands is an unsigned integer, the result is unsigned. You can override this by using the [SIGNED](#) and [UNSIGNED](#) cast operators to cast the operation to a signed or unsigned 64-bit integer, respectively.

```
mysql> SELECT CAST(1-2 AS UNSIGNED)
-> 18446744073709551615
mysql> SELECT CAST(CAST(1-2 AS UNSIGNED) AS SIGNED);
-> -1
```

Note that if either operand is a floating-point value, the result is a floating-point value and is not affected by the preceding rule. (In this context, [DECIMAL](#) column values are regarded as floating-point values.)

```
mysql> SELECT CAST(1 AS UNSIGNED) - 2.0;
-> -1.0
```

If you are using a string in an arithmetic operation, this is converted to a floating-point number.

If you convert a “zero” date string to a date, `CONVERT()` and `CAST()` return [NULL](#) and produce a warning when the [NO_ZERO_DATE](#) SQL mode is enabled.

11.10. XML Functions

Name	Description
ExtractValue() (v5.1.5)	Extracts a value from an XML string using XPath notation
UpdateXML() (v5.1.5)	Return replaced XML fragment

This section discusses XML and related functionality in MySQL.

Note

It is possible to obtain XML-formatted output from MySQL in the `mysql` and `mysqldump` clients by invoking them with the `--xml` option. See [Section 7.8, “mysql — The MySQL Command-Line Tool”](#), and [Section 7.13, “mysqldump — A Database Backup Program”](#).

Beginning with MySQL 5.1.5, two functions providing basic XPath (XML Path Language) capabilities are available.

Note

These functions remain under development. We continue to improve these and other aspects of XML and XPath functionality in MySQL 5.1 and onwards. You may discuss these, ask questions about them, and obtain help from other users with them in the [MySQL XML User Forum](#).

Beginning with MySQL 5.1.20, user variables in the XPath expressions used with these functions are supported in two forms, whose notations differ according to whether they are weakly or strongly checked (see also [Bug#26518](#)):

- **Weak checking.** Variables using the syntax `$@variable_name` are not checked. No warnings or errors are issued by the server if a variable has the wrong type or has previously been assigned a value. This also means the user is fully responsible for any typographical errors, since no warnings will be given if (for example) `$@myvairable` is used where `$@myvariable` was intended.
- **Strong checking.** Variables using the syntax `$variable_name` can be declared and used with these functions when they are called inside stored procedures. Such variables are local to the stored procedure in which they are defined, and are strongly checked for type and value.

Expressions containing user-defined variables of either sort must otherwise (except for notation) conform to the rules for XPath expressions containing variables as given in the XPath specification.

- `ExtractValue(xml_frag, xpath_expr)`

`ExtractValue()` takes two string arguments, a fragment of XML markup `xml_frag` and an XPath expression `xpath_expr` (also known as a *locator*); it returns the text (CDATA) of the first text node which is a child of the element(s) matched by the XPath expression. It is the equivalent of performing a match using the `xpath_expr` after appending `/text()`. In other words, `ExtractValue('<a><b>Sakila</b></a>', '/a/b')` and `ExtractValue('<a><b>Sakila</b></a>', '/a/b/text()')` produce the same result.

If multiple matches are found, then the content of the first child text node of each matching element is returned (in the order matched) as a single, space-delimited string.

If no matching text node is found for the (augmented) expression — for whatever reason, as long as `xpth_expr` is valid, and `xml_frag` is well-formed — an empty string is returned. No distinction is made between a match on an empty element and no match at all. This is by design.

If you need to determine whether no matching element was found in `xml_frag` or such an element was found but contained no child text nodes, you should test the result of an expression that uses the XPath `count()` function. For example, both of these statements return an empty string, as shown here:

```
mysql> SELECT ExtractValue('<a><b></a>', '/a/b');
+-----+
| ExtractValue('<a><b></a>', '/a/b') |
+-----+
|                                     |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a><c></a>', '/a/b');
+-----+
| ExtractValue('<a><c></a>', '/a/b') |
+-----+
|                                     |
+-----+
1 row in set (0.00 sec)
```

However, you can determine whether there was actually a matching element using the following:

```
mysql> SELECT ExtractValue('<a><b></a>', 'count(/a/b)');
+-----+
| ExtractValue('<a><b></a>', 'count(/a/b)') |
+-----+
| 1 |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a><c></a>', 'count(/a/b)');
+-----+
| ExtractValue('<a><c></a>', 'count(/a/b)') |
+-----+
| 0 |
+-----+
1 row in set (0.01 sec)
```

Important

`ExtractValue()` returns only `CDATA`, and does not return any tags that might be contained within a matching tag, nor any of their content (see the result returned as `val1` in the following example).

```
mysql> SELECT
-> ExtractValue('<a>ccc<b>ddd</b></a>', '/a') AS val1,
-> ExtractValue('<a>ccc<b>ddd</b></a>', '/a/b') AS val2,
-> ExtractValue('<a>ccc<b>ddd</b></a>', '//b') AS val3,
-> ExtractValue('<a>ccc<b>ddd</b></a>', '/b') AS val4,
-> ExtractValue('<a>ccc<b>ddd</b><b>eee</b></a>', '//b') AS val5;

+-----+-----+-----+-----+-----+
| val1 | val2 | val3 | val4 | val5 |
+-----+-----+-----+-----+-----+
| ccc  | ddd  | ddd  |      | ddd eee |
+-----+-----+-----+-----+-----+
```

Beginning with MySQL 5.1.8, this function uses the current SQL collation for making comparisons with `contains()`. (Previously, binary — that is, case-sensitive — comparison was always used.)

Beginning with MySQL 5.1.12, `NULL` is returned if `xml_frag` is invalid XML, and a warning is generated, as shown in this example:

```
mysql> SELECT ExtractValue('<a>c</a><b>', '//a');
+-----+
| ExtractValue('<a>c</a><b>', '//a') |
+-----+
| NULL                               |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message
+-----+-----+-----+
| Warning | 1523 | Incorrect XML value: 'parse error at line 1 pos 11: END-OF-INPUT unexpected ('>' wanted)'
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a>c</a><b/>', '//a');
+-----+
| ExtractValue('<a>c</a><b/>', '//a') |
+-----+
| c                                   |
+-----+
1 row in set (0.00 sec)
```

Prior to MySQL 5.1.12, an empty string was returned in such cases. ([Bug#18201](#))

- `UpdateXML(xml_target, xpath_expr, new_xml)`

This function replaces a single portion of a given fragment of XML markup `xml_target` with a new XML fragment `new_xml`, and then returns the changed XML. The portion of `xml_target` that is replaced matches an XPath expression `xpath_expr` supplied by the user. If no expression matching `xpath_expr` is found, or if multiple matches are found, the function returns the original `xml_target` XML fragment. All three arguments must be strings.

```
mysql> SELECT
-> UpdateXML('<a><b>ccc</b><d></d></a>', '/a', '<e>fff</e>') AS val1,
-> UpdateXML('<a><b>ccc</b><d></d></a>', '/b', '<e>fff</e>') AS val2,
-> UpdateXML('<a><b>ccc</b><d></d></a>', '//b', '<e>fff</e>') AS val3,
-> UpdateXML('<a><b>ccc</b><d></d></a>', '/a/d', '<e>fff</e>') AS val4,
-> UpdateXML('<a><d></d><b>ccc</b><d></d></a>', '/a/d', '<e>fff</e>') AS val5
-> \G

***** 1. row *****
val1: <e>fff</e>
val2: <a><b>ccc</b><d></d></a>
val3: <a><e>fff</e><d></d></a>
val4: <a><b>ccc</b><e>fff</e><d></d></a>
val5: <a><d></d><b>ccc</b><d></d></a>
```

Descriptions and examples of some basic XPath expressions follow:

- `/tag`

Matches `<tag/>` if and only if `<tag/>` is the root element.

Example: `/a` has a match in `<a><b/></a>` because it matches the outermost (root) tag. It does not match the inner `a` element in `<b><a/></b>` because in this instance it is the child of another element.

- `/tag1/tag2`

Matches `<tag2/>` if and only if it is a child of `<tag1/>`, and `<tag1/>` is the root element.

Example: `/a/b` matches the `b` element in the XML fragment `<a><b/></a>` because it is a child of the root element `a`. It does not have a match in `<b><a/></b>` because in this case, `b` is the root element (and hence the child of no other element). Nor does the XPath expression have a match in `<a><c><b/></c></a>`; here, `b` is a descendant of `a`, but not actually a child of `a`.

This construct is extendable to three or more elements. For example, the XPath expression `/a/b/c` matches the `c` element in the fragment `<a><b><c/></b></a>`.

- `//tag`

Matches any instance of `<tag>`.

Example: `//a` matches the `a` element in any of the following: `<a><b><c/></b></a>`; `<c><a><b/></a></b>`; `<c><b><a/></b></c>`.

`//` can be combined with `/`. For example, `//a/b` matches the `b` element in either of the fragments `<a><b/></a>` or `<a><b><c/></b></a>`.

- The `*` operator acts as a “wildcard” that matches any element. For example, the expression `/*/b` matches the `b` element in either of the XML fragments `<a><b/></a>` or `<c><b/></c>`. However, the expression does not produce a match in the fragment `<b><a/></b>` because `b` must be a child of some other element. The wildcard may be used in any position: The expression `/*/*b/*` will match any child of a `b` element that is itself not the root element.
- Multiple locators may be matched using the `|` (logical OR) operator. For example, the expression `//b|//c` matches all `b` and `c` elements in the XML target.
- It is also possible to match an element based on the value of one or more of its attributes. This done using the syntax `tag[@attribute="value"]`. For example, the expression `//b[@id="idB"]` matches the second `b` element in the fragment `<a><b id="idA"/><c/><b id="idB"/></a>`. To match against any element having `attribute="value"`, use the XPath expression `//*[attribute="value"]`.

To filter multiple attribute values, simply use multiple attribute-comparison clauses in succession. For example, the expression `/b[@c="x"][@d="y"]` matches the element `<b c="x" d="y"/>` occurring anywhere in a given XML fragment.

To find elements for which the same attribute matches one of several values, you must use multiple locators joined by the `|` operator. For example, to match all `b` elements whose `c` attributes have either of the values 23 or 17, use the expression `/b[@c="23"]|b[@c="17"]`.

Note

A discussion in depth of XPath syntax and usage are beyond the scope of this Manual. Please see the [XML Path Language \(XPath\) 1.0 standard](#) for definitive information. A useful resource for those new to XPath or who are wishing a refresher in the basics is the [Zvon.org XPath Tutorial](#), which is available in several languages.

The XPath syntax supported by these functions is currently subject to the following limitations:

- Prior to MySQL 5.1.14, nodeset-to-nodeset comparison (such as `'/a/b[@c=@d]'`) was not supported, and equality and inequality (`=` and `!=`) were the only supported comparison operators. Beginning with MySQL 5.1.14, all of the standard XPath comparison operators are supported. ([Bug#22823](#))
- Relative locator expressions are not supported. XPath expressions must begin with `/` or `//`.
- The `::` operator is not supported.

- “Up-and-down” navigation is not supported in cases where the path would lead “above” the root element. That is, you cannot use expressions which match on descendants of ancestors of a given element, where one or more of the ancestors of the current element is also an ancestor of the root element (see [Bug#16321](#)).
- The following XPath functions are not supported:
 - `id()`
 - `lang()`
 - Prior to MySQL 5.1.8, the `last()` function was not supported (see [Bug#16318](#)).
 - `local-name()`
 - `name()`
 - `namespace-uri()`
 - `normalize-space()`
 - `starts-with()`
 - `string()`
 - `substring-after()`
 - `substring-before()`
 - `translate()`
- The following axes are not supported:
 - `following-sibling`
 - `following`
 - `preceding-sibling`
 - `preceding`

Beginning with MySQL 5.1.10, XPath expressions passed as arguments to `ExtractValue()` and `UpdateXML()` may contain the colon character (“:”) in element selectors, which enables their use with markup employing XML namespaces notation. For example:

```
mysql> SET @xml = '<a>111<b:c>222<d>333</d><e:f>444</e:f></b:c></a>';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT ExtractValue(@xml, '//e:f');
+-----+
| ExtractValue(@xml, '//e:f') |
+-----+
| 444                          |
+-----+
1 row in set (0.00 sec)

mysql> SELECT UpdateXML(@xml, '//b:c', '<g:h>555</g:h>');
+-----+
| UpdateXML(@xml, '//b:c', '<g:h>555</g:h>') |
+-----+
| <a>111<g:h>555</g:h></a>                  |
+-----+
1 row in set (0.00 sec)
```

This is similar in some respects to what is allowed by [Apache Xalan](#) and some other parsers, and is much simpler than requiring namespace declarations or the use of the `namespace-uri()` and `local-name()` functions.

Error handling. For both `ExtractValue()` and `UpdateXML()`, the XPath locator used must be valid and the XML to be searched must be well-formed. If the locator is invalid, an error is generated:

```
mysql> SELECT ExtractValue('<a>c</a><b/>', '&a');
ERROR 1105 (HY000): XPATH SYNTAX ERROR: '&a'
```

If `xml_frag` is invalid XML, then, beginning with MySQL 5.1.12, `NULL` is returned, and a warning is generated, as shown in this example:

```
mysql> SELECT ExtractValue('<a>c</a><b', '//@a');
+-----+
| ExtractValue('<a>c</a><b', '//@a') |
+-----+
| NULL |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1523 | Incorrect XML value: 'parse error at line 1 pos 11: END-OF-INPUT unexpected ('>' wanted)' |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a>c</a><b/>', '//@a');
+-----+
| ExtractValue('<a>c</a><b/>', '//@a') |
+-----+
| c |
+-----+
1 row in set (0.00 sec)
```

Prior to MySQL 5.1.12, an empty string was returned in such cases. ([Bug#18201](#))

Important

The replacement XML used as the third argument to `UpdateXML()` is *not* checked for well-formedness.

11.11. Other Functions

Name	Description
<code>AES_DECRYPT()</code>	Decrypt using AES
<code>AES_ENCRYPT()</code>	Encrypt using AES
<code>BENCHMARK()</code>	Repeatedly execute an expression
<code>BIT_COUNT()</code>	Return the number of bits that are set
<code>&</code>	Bitwise AND
<code> </code>	Bitwise OR
<code>^</code>	Bitwise XOR
<code>CHARSET()</code> (v4.1.0)	Return the character set of the argument
<code>COERCIBILITY()</code> (v4.1.1)	Return the collation coercibility value of the string argument
<code>COLLATION()</code> (v4.1.0)	Return the collation of the string argument
<code>COMPRESS()</code> (v4.1.1)	Return result as a binary string
<code>CONNECTION_ID()</code>	Return the connection ID (thread ID) for the connection
<code>CURRENT_USER()</code> , <code>CURRENT_USER</code>	Return the username and hostname combination
<code>DATABASE()</code>	Return the default (current) database name
<code>DECODE()</code>	Decodes a string encrypted using <code>ENCODE()</code>
<code>DEFAULT()</code>	Return the default value for a table column
<code>DES_DECRYPT()</code>	Decrypt a string
<code>DES_ENCRYPT()</code>	Decrypt a string
<code>ENCODE()</code>	Encode a string
<code>ENCRYPT()</code>	Encrypt a string
<code>FOUND_ROWS()</code>	For a <code>SELECT</code> with a <code>LIMIT</code> clause, the number of rows that would be returned were there no <code>LIMIT</code> clause
<code>GET_LOCK()</code>	Get a named lock
<code>INET_ATON()</code>	Return the numeric value of an IP address

Name	Description
INET_NTOA()	Return the IP address from a numeric value
IS_FREE_LOCK()	Checks whether the named lock is free
IS_USED_LOCK() (v4.1.0)	Checks whether the named lock is in use. Return connection identifier if true.
LAST_INSERT_ID()	Value of the AUTOINCREMENT column for the last INSERT
<<	Left shift
MASTER_POS_WAIT()	Block until the slave has read and applied all updates up to the specified position
MD5()	Calculate MD5 checksum
NAME_CONST() (v5.0.12)	Causes the column to have the given name
OLD_PASSWORD() (v4.1)	Return the value of the old (pre-4.1) implementation of PASSWORD
PASSWORD()	Calculate and return a password string
RELEASE_LOCK()	Releases the named lock
>>	Right shift
ROW_COUNT() (v5.0.1)	The number of rows updated
SCHEMA() (v5.0.2)	A synonym for DATABASE()
SESSION_USER()	Synonym for USER()
SHA1() , SHA()	Calculate an SHA-1 160-bit checksum
SLEEP() (v5.0.12)	Sleep for a number of seconds
SYSTEM_USER()	Synonym for USER()
~	Invert bits
UNCOMPRESS() (v4.1.1)	Uncompress a string compressed
UNCOMPRESSED_LENGTH() (v4.1.1)	Return the length of a string before compression
USER()	Return the current username and hostname
UUID() (v4.1.2)	Return a Universal Unique Identifier (UUID)
VALUES() (v4.1.1)	Defines the values to be used during an INSERT
VERSION()	Returns a string that indicates the MySQL server version

11.11.1. Bit Functions

Name	Description
BIT_COUNT()	Return the number of bits that are set
&	Bitwise AND
 	Bitwise OR
^	Bitwise XOR
<<	Left shift
>>	Right shift
~	Invert bits

MySQL uses [BIGINT](#) (64-bit) arithmetic for bit operations, so these operators have a maximum range of 64 bits.

- [|](#)

Bitwise OR:

```
mysql> SELECT 29 | 15;
-> 31
```

The result is an unsigned 64-bit integer.

- **&**

Bitwise AND:

```
mysql> SELECT 29 & 15;
-> 13
```

The result is an unsigned 64-bit integer.

- **^**

Bitwise XOR:

```
mysql> SELECT 1 ^ 1;
-> 0
mysql> SELECT 1 ^ 0;
-> 1
mysql> SELECT 11 ^ 3;
-> 8
```

The result is an unsigned 64-bit integer.

- **<<**

Shifts a longlong (**BIGINT**) number to the left.

```
mysql> SELECT 1 << 2;
-> 4
```

The result is an unsigned 64-bit integer.

- **>>**

Shifts a longlong (**BIGINT**) number to the right.

```
mysql> SELECT 4 >> 2;
-> 1
```

The result is an unsigned 64-bit integer.

- **~**

Invert all bits.

```
mysql> SELECT 5 & ~1;
-> 4
```

The result is an unsigned 64-bit integer.

- **BIT_COUNT(*N*)**

Returns the number of bits that are set in the argument *N*.

```
mysql> SELECT BIT_COUNT(29), BIT_COUNT(b'101010');
-> 4, 3
```

11.11.2. Encryption and Compression Functions

Name	Description
AES_DECRYPT()	Decrypt using AES
AES_ENCRYPT()	Encrypt using AES

Name	Description
COMPRESS() (v4.1.1)	Return result as a binary string
DECODE()	Decodes a string encrypted using ENCODE()
DES_DECRYPT()	Decrypt a string
DES_ENCRYPT()	Encrypt a string
ENCODE()	Encode a string
ENCRYPT()	Encrypt a string
MD5()	Calculate MD5 checksum
OLD_PASSWORD() (v4.1)	Return the value of the old (pre-4.1) implementation of PASSWORD
PASSWORD()	Calculate and return a password string
SHA1() , SHA()	Calculate an SHA-1 160-bit checksum
UNCOMPRESS() (v4.1.1)	Uncompress a string compressed
UNCOMPRESSED_LENGTH() (v4.1.1)	Return the length of a string before compression

The functions in this section perform encryption and decryption, and compression and uncompression:

Compression or encryption	Uncompression or decryption
AES_ENCRYPT()	AES_DECRYPT()
COMPRESS()	UNCOMPRESS()
ENCODE()	DECODE()
DES_ENCRYPT()	DES_DECRYPT()
ENCRYPT()	Not available
MD5()	Not available
OLD_PASSWORD()	Not available
PASSWORD()	Not available
SHA() or SHA1()	Not available
Not available	UNCOMPRESSED_LENGTH()

Note

The encryption and compression functions return binary strings. For many of these functions, the result might contain arbitrary byte values. If you want to store these results, use a [BLOB](#) column rather than a [CHAR](#) or [VARCHAR](#) column to avoid potential problems with trailing space removal that would change data values.

Note

Exploits for the MD5 and SHA-1 algorithms have become known. You may wish to consider using one of the other encryption functions described in this section instead.

- [AES_ENCRYPT\(str, key_str\)](#), [AES_DECRYPT\(encrypt_str, key_str\)](#)

These functions allow encryption and decryption of data using the official AES (Advanced Encryption Standard) algorithm, previously known as “Rijndael.” Encoding with a 128-bit key length is used, but you can extend it up to 256 bits by modifying the source. We chose 128 bits because it is much faster and it is secure enough for most purposes.

[AES_ENCRYPT\(\)](#) encrypts a string and returns a binary string. [AES_DECRYPT\(\)](#) decrypts the encrypted string and returns the original string. The input arguments may be any length. If either argument is [NULL](#), the result of this function is also [NULL](#).

Because AES is a block-level algorithm, padding is used to encode uneven length strings and so the result string length may be calculated using this formula:

$$16 \times (\text{trunc}(\text{string\_length} / 16) + 1)$$

If `AES_DECRYPT()` detects invalid data or incorrect padding, it returns `NULL`. However, it is possible for `AES_DECRYPT()` to return a non-`NULL` value (possibly garbage) if the input data or the key is invalid.

You can use the AES functions to store data in an encrypted form by modifying your queries:

```
INSERT INTO t VALUES (1,AES_ENCRYPT('text','password'));
```

`AES_ENCRYPT()` and `AES_DECRYPT()` can be considered the most cryptographically secure encryption functions currently available in MySQL.

- `COMPRESS(string_to_compress)`

Compresses a string and returns the result as a binary string. This function requires MySQL to have been compiled with a compression library such as `zlib`. Otherwise, the return value is always `NULL`. The compressed string can be uncompressed with `UNCOMPRESS()`.

```
mysql> SELECT LENGTH(COMPRESS(REPEAT('a',1000)));
-> 21
mysql> SELECT LENGTH(COMPRESS(''));
-> 0
mysql> SELECT LENGTH(COMPRESS('a'));
-> 13
mysql> SELECT LENGTH(COMPRESS(REPEAT('a',16)));
-> 15
```

The compressed string contents are stored the following way:

- Empty strings are stored as empty strings.
- Non-empty strings are stored as a four-byte length of the uncompressed string (low byte first), followed by the compressed string. If the string ends with space, an extra `'.'` character is added to avoid problems with endspace trimming should the result be stored in a `CHAR` or `VARCHAR` column. (Use of `CHAR` or `VARCHAR` to store compressed strings is not recommended. It is better to use a `BLOB` column instead.)
- `DECODE(encrypt_str,pass_str)`

Decrypts the encrypted string `encrypt_str` using `pass_str` as the password. `encrypt_str` should be a string returned from `ENCODE()`.

- `ENCODE(str,pass_str)`

Encrypt `str` using `pass_str` as the password. To decrypt the result, use `DECODE()`.

The result is a binary string of the same length as `str`.

The strength of the encryption is based on how good the random generator is. It should suffice for short strings.

- `DES_DECRYPT(encrypt_str[,key_str])`

Decrypts a string encrypted with `DES_ENCRYPT()`. If an error occurs, this function returns `NULL`.

Note that this function works only if MySQL has been configured with SSL support. See [Section 5.8.7, “Using Secure Connections”](#).

If no `key_str` argument is given, `DES_DECRYPT()` examines the first byte of the encrypted string to determine the DES key number that was used to encrypt the original string, and then reads the key from the DES key file to decrypt the message. For this to work, the user must have the `SUPER` privilege. The key file can be specified with the `--des-key-file` server option.

If you pass this function a `key_str` argument, that string is used as the key for decrypting the message.

If the `encrypt_str` argument does not appear to be an encrypted string, MySQL returns the given `encrypt_str`.

- `DES_ENCRYPT(str[,key_num|key_str])`

Encrypts the string with the given key using the Triple-DES algorithm.

Note that this function works only if MySQL has been configured with SSL support. See [Section 5.8.7, “Using Secure Connections”](#).

The encryption key to use is chosen based on the second argument to `DES_ENCRYPT()`, if one was given:

Argument	Description
No argument	The first key from the DES key file is used.
<i>key_num</i>	The given key number (0-9) from the DES key file is used.
<i>key_str</i>	The given key string is used to encrypt <i>str</i> .

The key file can be specified with the `--des-key-file` server option.

The return string is a binary string where the first character is `CHAR(128 | key_num)`. If an error occurs, `DES_ENCRYPT()` returns `NULL`.

The 128 is added to make it easier to recognize an encrypted key. If you use a string key, *key_num* is 127.

The string length for the result is given by this formula:

```
new_len = orig_len + (8 - (orig_len % 8)) + 1
```

Each line in the DES key file has the following format:

```
key_num des_key_str
```

Each *key_num* value must be a number in the range from 0 to 9. Lines in the file may be in any order. *des_key_str* is the string that is used to encrypt the message. There should be at least one space between the number and the key. The first key is the default key that is used if you do not specify any key argument to `DES_ENCRYPT()`.

You can tell MySQL to read new key values from the key file with the `FLUSH DES_KEY_FILE` statement. This requires the `RELOAD` privilege.

One benefit of having a set of default keys is that it gives applications a way to check for the existence of encrypted column values, without giving the end user the right to decrypt those values.

```
mysql> SELECT customer_address FROM customer_table
> WHERE crypted_credit_card = DES_ENCRYPT('credit_card_number');
```

- `ENCRYPT(str [, salt])`

Encrypts *str* using the Unix `crypt()` system call and returns a binary string. The *salt* argument should be a string with at least two characters. If no *salt* argument is given, a random value is used.

```
mysql> SELECT ENCRYPT('hello');
-> 'VxuFAJXVAR0c'
```

`ENCRYPT()` ignores all but the first eight characters of *str*, at least on some systems. This behavior is determined by the implementation of the underlying `crypt()` system call.

The use of `ENCRYPT()` with multi-byte character sets other than `utf8` is not recommended because the system call expects a string terminated by a zero byte.

If `crypt()` is not available on your system (as is the case with Windows), `ENCRYPT()` always returns `NULL`.

- `MD5(str)`

Calculates an MD5 128-bit checksum for the string. The value is returned as a binary string of 32 hex digits, or `NULL` if the argument was `NULL`. The return value can, for example, be used as a hash key.

```
mysql> SELECT MD5('testing');
-> 'ae2b1fca515949e5d54fb22b8ed95575'
```

This is the “RSA Data Security, Inc. MD5 Message-Digest Algorithm.”

If you want to convert the value to uppercase, see the description of binary string conversion given in the entry for the [BINARY](#) operator in [Section 11.9, “Cast Functions and Operators”](#).

See the note regarding the MD5 algorithm at the beginning this section.

- [OLD_PASSWORD\(*str*\)](#)

[OLD_PASSWORD\(\)](#) was added to MySQL when the implementation of [PASSWORD\(\)](#) was changed to improve security. [OLD_PASSWORD\(\)](#) returns the value of the old (pre-4.1) implementation of [PASSWORD\(\)](#) as a binary string, and is intended to permit you to reset passwords for any pre-4.1 clients that need to connect to your version 5.1 MySQL server without locking them out. See [Section 5.7.9, “Password Hashing as of MySQL 4.1”](#).

- [PASSWORD\(*str*\)](#)

Calculates and returns a password string from the plaintext password *str* and returns a binary string, or [NULL](#) if the argument was [NULL](#). This is the function that is used for encrypting MySQL passwords for storage in the [Password](#) column of the [user](#) grant table.

```
mysql> SELECT PASSWORD('badpwd');
-> '*AAB3E285149C0135D51A520E1940DD3263DC008C'
```

[PASSWORD\(\)](#) encryption is one-way (not reversible).

[PASSWORD\(\)](#) does not perform password encryption in the same way that Unix passwords are encrypted. See [ENCRYPT\(\)](#).

Note

The [PASSWORD\(\)](#) function is used by the authentication system in MySQL Server; you should *not* use it in your own applications. For that purpose, consider [MD5\(\)](#) or [SHA1\(\)](#) instead. Also see [RFC 2195, section 2 \(Challenge-Response Authentication Mechanism \(CRAM\)\)](#), for more information about handling passwords and authentication securely in your applications.

- [SHA1\(*str*\)](#), [SHA\(*str*\)](#)

Calculates an SHA-1 160-bit checksum for the string, as described in RFC 3174 (Secure Hash Algorithm). The value is returned as a binary string of 40 hex digits, or [NULL](#) if the argument was [NULL](#). One of the possible uses for this function is as a hash key. You can also use it as a cryptographic function for storing passwords. [SHA\(\)](#) is synonymous with [SHA1\(\)](#).

```
mysql> SELECT SHA1('abc');
-> 'a9993e364706816aba3e25717850c26c9cd0d89d'
```

[SHA1\(\)](#) can be considered a cryptographically more secure equivalent of [MD5\(\)](#). However, see the note regarding the MD5 and SHA-1 algorithms at the beginning this section.

- [UNCOMPRESS\(*string_to_uncompress*\)](#)

Uncompresses a string compressed by the [COMPRESS\(\)](#) function. If the argument is not a compressed value, the result is [NULL](#). This function requires MySQL to have been compiled with a compression library such as [zlib](#). Otherwise, the return value is always [NULL](#).

```
mysql> SELECT UNCOMPRESS(COMPRESS('any string'));
-> 'any string'
mysql> SELECT UNCOMPRESS('any string');
-> NULL
```

- [UNCOMPRESSED_LENGTH\(*compressed_string*\)](#)

Returns the length that the compressed string had before being compressed.

```
mysql> SELECT UNCOMPRESSED_LENGTH(COMPRESS(REPEAT('a', 30)));
-> 30
```

11.11.3. Information Functions

Name	Description
<code>BENCHMARK()</code>	Repeatedly execute an expression
<code>CHARSET()</code> (v4.1.0)	Return the character set of the argument
<code>COERCIBILITY()</code> (v4.1.1)	Return the collation coercibility value of the string argument
<code>COLLATION()</code> (v4.1.0)	Return the collation of the string argument
<code>CONNECTION_ID()</code>	Return the connection ID (thread ID) for the connection
<code>CURRENT_USER()</code> , <code>CURRENT_USER</code>	Return the username and hostname combination
<code>DATABASE()</code>	Return the default (current) database name
<code>FOUND_ROWS()</code>	For a <code>SELECT</code> with a <code>LIMIT</code> clause, the number of rows that would be returned were there no <code>LIMIT</code> clause
<code>LAST_INSERT_ID()</code>	Value of the <code>AUTOINCREMENT</code> column for the last <code>INSERT</code>
<code>ROW_COUNT()</code> (v5.0.1)	The number of rows updated
<code>SCHEMA()</code> (v5.0.2)	A synonym for <code>DATABASE()</code>
<code>SESSION_USER()</code>	Synonym for <code>USER()</code>
<code>SYSTEM_USER()</code>	Synonym for <code>USER()</code>
<code>USER()</code>	Return the current username and hostname
<code>VERSION()</code>	Returns a string that indicates the MySQL server version

- `BENCHMARK(count, expr)`

The `BENCHMARK()` function executes the expression *expr* repeatedly *count* times. It may be used to time how quickly MySQL processes the expression. The result value is always 0. The intended use is from within the `mysql` client, which reports query execution times:

```
mysql> SELECT BENCHMARK(1000000, ENCODE('hello', 'goodbye'));
+-----+
| BENCHMARK(1000000, ENCODE('hello', 'goodbye')) |
+-----+
| 0 |
+-----+
1 row in set (4.74 sec)
```

The time reported is elapsed time on the client end, not CPU time on the server end. It is advisable to execute `BENCHMARK()` several times, and to interpret the result with regard to how heavily loaded the server machine is.

`BENCHMARK()` is intended for measuring the runtime performance of scalar expressions, which has some significant implications for the way that you use it and interpret the results:

- Only scalar expressions can be used. Although the expression can be a subquery, it must return a single column and at most a single row. For example, `BENCHMARK(10, (SELECT * FROM t))` will fail if the table `t` has more than one column or more than one row.
- Executing a `SELECT expr` statement *N* times differs from executing `SELECT BENCHMARK(N, expr)` in terms of the amount of overhead involved. The two have very different execution profiles and you should not expect them to take the same amount of time. The former involves the parser, optimizer, table locking, and runtime evaluation *N* times each. The latter involves only runtime evaluation *N* times, and all the other components just once. Memory structures already allocated are reused, and runtime optimizations such as local caching of results already evaluated for aggregate functions can alter the results. Use of `BENCHMARK()` thus measures performance of the runtime component by giving more weight to that component and removing the “noise” introduced by the network, parser, optimizer, and so forth.
- `CHARSET(str)`

Returns the character set of the string argument.

```
mysql> SELECT CHARSET('abc');
-> 'latin1'
mysql> SELECT CHARSET(CONVERT('abc' USING utf8));
```

```
mysql> -> 'utf8'
mysql> SELECT CHARSET(USER());
mysql> -> 'utf8'
```

- **COERCIBILITY(*str*)**

Returns the collation coercibility value of the string argument.

```
mysql> SELECT COERCIBILITY('abc' COLLATE latin1_swedish_ci);
mysql> -> 0
mysql> SELECT COERCIBILITY(USER());
mysql> -> 3
mysql> SELECT COERCIBILITY('abc');
```

The return values have the meanings shown in the following table. Lower values have higher precedence.

Coercibility	Meaning	Example
0	Explicit collation	Value with COLLATE clause
1	No collation	Concatenation of strings with different collations
2	Implicit collation	Column value, stored routine parameter or local variable
3	System constant	USER() return value
4	Coercible	Literal string
5	Ignorable	NULL or an expression derived from NULL

- **COLLATION(*str*)**

Returns the collation of the string argument.

```
mysql> SELECT COLLATION('abc');
mysql> -> 'latin1_swedish_ci'
mysql> SELECT COLLATION(_utf8'abc');
mysql> -> 'utf8_general_ci'
```

- **CONNECTION_ID()**

Returns the connection ID (thread ID) for the connection. Every connection has an ID that is unique among the set of currently connected clients.

```
mysql> SELECT CONNECTION_ID();
mysql> -> 23786
```

- **CURRENT_USER, CURRENT_USER()**

Returns the username and hostname combination for the MySQL account that the server used to authenticate the current client. This account determines your access privileges. Within a stored routine that is defined with the **SQL SECURITY DEFINER** characteristic, **CURRENT_USER()** returns the creator of the routine. The return value is a string in the **utf8** character set.

The value of **CURRENT_USER()** can differ from the value of **USER()**.

```
mysql> SELECT USER();
mysql> -> 'davida@localhost'
mysql> SELECT * FROM mysql.user;
ERROR 1044: Access denied for user ''@'localhost' to
database 'mysql'
mysql> SELECT CURRENT_USER();
mysql> -> '@localhost'
```

The example illustrates that although the client specified a username of **davida** (as indicated by the value of the **USER()** function), the server authenticated the client using an anonymous user account (as seen by the empty username part of the **CURRENT_USER()** value). One way this might occur is that there is no account listed in the grant tables for **davida**.

- **DATABASE()**

Returns the default (current) database name as a string in the `utf8` character set. If there is no default database, `DATABASE()` returns `NULL`. Within a stored routine, the default database is the database that the routine is associated with, which is not necessarily the same as the database that is the default in the calling context.

```
mysql> SELECT DATABASE();
-> 'test'
```

If there is no default database, `DATABASE()` returns `NULL`.

- `FOUND_ROWS()`

A `SELECT` statement may include a `LIMIT` clause to restrict the number of rows the server returns to the client. In some cases, it is desirable to know how many rows the statement would have returned without the `LIMIT`, but without running the statement again. To obtain this row count, include a `SQL_CALC_FOUND_ROWS` option in the `SELECT` statement, and then invoke `FOUND_ROWS()` afterward:

```
mysql> SELECT SQL_CALC_FOUND_ROWS * FROM tbl_name
-> WHERE id > 100 LIMIT 10;
mysql> SELECT FOUND_ROWS();
```

The second `SELECT` returns a number indicating how many rows the first `SELECT` would have returned had it been written without the `LIMIT` clause.

In the absence of the `SQL_CALC_FOUND_ROWS` option in the most recent `SELECT` statement, `FOUND_ROWS()` returns the number of rows in the result set returned by that statement.

The row count available through `FOUND_ROWS()` is transient and not intended to be available past the statement following the `SELECT SQL_CALC_FOUND_ROWS` statement. If you need to refer to the value later, save it:

```
mysql> SELECT SQL_CALC_FOUND_ROWS * FROM ... ;
mysql> SET @rows = FOUND_ROWS();
```

If you are using `SELECT SQL_CALC_FOUND_ROWS`, MySQL must calculate how many rows are in the full result set. However, this is faster than running the query again without `LIMIT`, because the result set need not be sent to the client.

`SQL_CALC_FOUND_ROWS` and `FOUND_ROWS()` can be useful in situations when you want to restrict the number of rows that a query returns, but also determine the number of rows in the full result set without running the query again. An example is a Web script that presents a paged display containing links to the pages that show other sections of a search result. Using `FOUND_ROWS()` allows you to determine how many other pages are needed for the rest of the result.

The use of `SQL_CALC_FOUND_ROWS` and `FOUND_ROWS()` is more complex for `UNION` statements than for simple `SELECT` statements, because `LIMIT` may occur at multiple places in a `UNION`. It may be applied to individual `SELECT` statements in the `UNION`, or global to the `UNION` result as a whole.

The intent of `SQL_CALC_FOUND_ROWS` for `UNION` is that it should return the row count that would be returned without a global `LIMIT`. The conditions for use of `SQL_CALC_FOUND_ROWS` with `UNION` are:

- The `SQL_CALC_FOUND_ROWS` keyword must appear in the first `SELECT` of the `UNION`.
- The value of `FOUND_ROWS()` is exact only if `UNION ALL` is used. If `UNION` without `ALL` is used, duplicate removal occurs and the value of `FOUND_ROWS()` is only approximate.
- If no `LIMIT` is present in the `UNION`, `SQL_CALC_FOUND_ROWS` is ignored and returns the number of rows in the temporary table that is created to process the `UNION`.
- `LAST_INSERT_ID()`, `LAST_INSERT_ID(expr)`

For MySQL 5.1.12 and later, `LAST_INSERT_ID()` (no arguments) returns the *first* automatically generated value *successfully* inserted for an `AUTO_INCREMENT` column as a result of the most recently executed `INSERT` statement. The value of `LAST_INSERT_ID()` remains unchanged if no rows are successfully inserted.

For example, after inserting a row that generates an `AUTO_INCREMENT` value, you can get the value like this:

```
mysql> SELECT LAST_INSERT_ID();
-> 195
```

In MySQL 5.1.11 and earlier, `LAST_INSERT_ID()` (no arguments) returns the *first* automatically generated value if any rows were successfully inserted or updated. This means that the returned value could be a value that was not successfully inserted into the table. If no rows were successfully inserted, `LAST_INSERT_ID()` returns 0.

The value of `LAST_INSERT_ID()` will be consistent across all versions if all rows in the `INSERT` or `UPDATE` statement were successful.

The currently executing statement does not affect the value of `LAST_INSERT_ID()`. Suppose that you generate an `AUTO_INCREMENT` value with one statement, and then refer to `LAST_INSERT_ID()` in a multiple-row `INSERT` statement that inserts rows into a table with its own `AUTO_INCREMENT` column. The value of `LAST_INSERT_ID()` will remain stable in the second statement; its value for the second and later rows is not affected by the earlier row insertions. (However, if you mix references to `LAST_INSERT_ID()` and `LAST_INSERT_ID(expr)`, the effect is undefined.)

If the previous statement returned an error, the value of `LAST_INSERT_ID()` is undefined. For transactional tables, if the statement is rolled back due to an error, the value of `LAST_INSERT_ID()` is left undefined. For manual `ROLLBACK`, the value of `LAST_INSERT_ID()` is not restored to that before the transaction; it remains as it was at the point of the `ROLLBACK`.

Within the body of a stored routine (procedure or function) or a trigger, the value of `LAST_INSERT_ID()` changes the same way as for statements executed outside the body of these kinds of objects. The effect of a stored routine or trigger upon the value of `LAST_INSERT_ID()` that is seen by following statements depends on the kind of routine:

- If a stored procedure executes statements that change the value of `LAST_INSERT_ID()`, the changed value will be seen by statements that follow the procedure call.
- For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so following statements will not see a changed value.

The ID that was generated is maintained in the server on a *per-connection basis*. This means that the value returned by the function to a given client is the first `AUTO_INCREMENT` value generated for most recent statement affecting an `AUTO_INCREMENT` column *by that client*. This value cannot be affected by other clients, even if they generate `AUTO_INCREMENT` values of their own. This behavior ensures that each client can retrieve its own ID without concern for the activity of other clients, and without the need for locks or transactions.

The value of `LAST_INSERT_ID()` is not changed if you set the `AUTO_INCREMENT` column of a row to a non-“magic” value (that is, a value that is not `NULL` and not 0).

Important

If you insert multiple rows using a single `INSERT` statement, `LAST_INSERT_ID()` returns the value generated for the *first* inserted row *only*. The reason for this is to make it possible to reproduce easily the same `INSERT` statement against some other server.

For example:

```
mysql> USE test;
Database changed
mysql> CREATE TABLE t (
->   id INT AUTO_INCREMENT NOT NULL PRIMARY KEY,
->   name VARCHAR(10) NOT NULL
-> );
Query OK, 0 rows affected (0.09 sec)

mysql> INSERT INTO t VALUES (NULL, 'Bob');
Query OK, 1 row affected (0.01 sec)

mysql> SELECT * FROM t;
+----+-----+
| id | name |
+----+-----+
|  1 | Bob  |
+----+-----+
1 row in set (0.01 sec)

mysql> SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
|                1 |
+-----+
1 row in set (0.00 sec)

mysql> INSERT INTO t VALUES
```

```
-> (NULL, 'Mary'), (NULL, 'Jane'), (NULL, 'Lisa');
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM t;
+----+-----+
| id | name |
+----+-----+
| 1  | Bob  |
| 2  | Mary |
| 3  | Jane |
| 4  | Lisa |
+----+-----+
4 rows in set (0.01 sec)

mysql> SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
| 2                |
+-----+
1 row in set (0.00 sec)
```

Although the second `INSERT` statement inserted three new rows into `t`, the ID generated for the first of these rows was `2`, and it is this value that is returned by `LAST_INSERT_ID()` for the following `SELECT` statement.

If you use `INSERT IGNORE` and the row is ignored, the `AUTO_INCREMENT` counter is not incremented and `LAST_INSERT_ID()` returns `0`, which reflects that no row was inserted.

If `expr` is given as an argument to `LAST_INSERT_ID()`, the value of the argument is returned by the function and is remembered as the next value to be returned by `LAST_INSERT_ID()`. This can be used to simulate sequences:

1. Create a table to hold the sequence counter and initialize it:

```
mysql> CREATE TABLE sequence (id INT NOT NULL);
mysql> INSERT INTO sequence VALUES (0);
```

2. Use the table to generate sequence numbers like this:

```
mysql> UPDATE sequence SET id=LAST_INSERT_ID(id+1);
mysql> SELECT LAST_INSERT_ID();
```

The `UPDATE` statement increments the sequence counter and causes the next call to `LAST_INSERT_ID()` to return the updated value. The `SELECT` statement retrieves that value. The `mysql_insert_id()` C API function can also be used to get the value. See [Section 25.2.3.37](#), “`mysql_insert_id()`”.

You can generate sequences without calling `LAST_INSERT_ID()`, but the utility of using the function this way is that the ID value is maintained in the server as the last automatically generated value. It is multi-user safe because multiple clients can issue the `UPDATE` statement and get their own sequence value with the `SELECT` statement (or `mysql_insert_id()`), without affecting or being affected by other clients that generate their own sequence values.

Note that `mysql_insert_id()` is only updated after `INSERT` and `UPDATE` statements, so you cannot use the C API function to retrieve the value for `LAST_INSERT_ID(expr)` after executing other SQL statements like `SELECT` or `SET`.

- **`ROW_COUNT()`**

`ROW_COUNT()` returns the number of rows updated, inserted, or deleted by the preceding statement. This is the same as the row count that the `mysql` client displays and the value from the `mysql_affected_rows()` C API function.

```
mysql> INSERT INTO t VALUES(1),(2),(3);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT ROW_COUNT();
+-----+
| ROW_COUNT() |
+-----+
| 3          |
+-----+
1 row in set (0.00 sec)

mysql> DELETE FROM t WHERE i IN(1,2);
Query OK, 2 rows affected (0.00 sec)

mysql> SELECT ROW_COUNT();
```

```
+-----+
| ROW_COUNT() |
+-----+
|          2 |
+-----+
1 row in set (0.00 sec)
```

- **SCHEMA()**

This function is a synonym for **DATABASE()**.

- **SESSION_USER()**

SESSION_USER() is a synonym for **USER()**.

- **SYSTEM_USER()**

SYSTEM_USER() is a synonym for **USER()**.

- **USER()**

Returns the current MySQL username and hostname as a string in the **utf8** character set.

```
mysql> SELECT USER();
-> 'davida@localhost'
```

The value indicates the username you specified when connecting to the server, and the client host from which you connected. The value can be different from that of **CURRENT_USER()**.

You can extract only the username part like this:

```
mysql> SELECT SUBSTRING_INDEX(USER(), '@', 1);
-> 'davida'
```

- **VERSION()**

Returns a string that indicates the MySQL server version. The string uses the **utf8** character set.

```
mysql> SELECT VERSION();
-> '5.1.21-beta-standard'
```

Note that if your version string ends with **-log** this means that logging is enabled.

11.11.4. Miscellaneous Functions

Name	Description
DEFAULT()	Return the default value for a table column
GET_LOCK()	Get a named lock
INET_ATON()	Return the numeric value of an IP address
INET_NTOA()	Return the IP address from a numeric value
IS_FREE_LOCK()	Checks whether the named lock is free
IS_USED_LOCK() (v4.1.0)	Checks whether the named lock is in use. Return connection identifier if true.
MASTER_POS_WAIT()	Block until the slave has read and applied all updates up to the specified position
NAME_CONST() (v5.0.12)	Causes the column to have the given name
RELEASE_LOCK()	Releases the named lock
SLEEP() (v5.0.12)	Sleep for a number of seconds
UUID() (v4.1.2)	Return a Universal Unique Identifier (UUID)
VALUES() (v4.1.1)	Defines the values to be used during an INSERT

- `DEFAULT(col_name)`

Returns the default value for a table column. An error results if the column has no default value.

```
mysql> UPDATE t SET i = DEFAULT(i)+1 WHERE id < 100;
```

- `FORMAT(X,D)`

Formats the number *X* to a format like '*#*,*###*,*###.###*', rounded to *D* decimal places, and returns the result as a string. For details, see [Section 11.4, “String Functions”](#).

- `GET_LOCK(str,timeout)`

Tries to obtain a lock with a name given by the string *str*, using a timeout of *timeout* seconds. Returns **1** if the lock was obtained successfully, **0** if the attempt timed out (for example, because another client has previously locked the name), or **NULL** if an error occurred (such as running out of memory or the thread was killed with `mysqladmin kill`). If you have a lock obtained with `GET_LOCK()`, it is released when you execute `RELEASE_LOCK()`, execute a new `GET_LOCK()`, or your connection terminates (either normally or abnormally). Locks obtained with `GET_LOCK()` do not interact with transactions. That is, committing a transaction does not release any such locks obtained during the transaction.

This function can be used to implement application locks or to simulate record locks. Names are locked on a server-wide basis. If a name has been locked by one client, `GET_LOCK()` blocks any request by another client for a lock with the same name. This allows clients that agree on a given lock name to use the name to perform cooperative advisory locking. But be aware that it also allows a client that is not among the set of cooperating clients to lock a name, either inadvertently or deliberately, and thus prevent any of the cooperating clients from locking that name. One way to reduce the likelihood of this is to use lock names that are database-specific or application-specific. For example, use lock names of the form *db_name.str* or *app_name.str*.

```
mysql> SELECT GET_LOCK('lock1',10);
-> 1
mysql> SELECT IS_FREE_LOCK('lock2');
-> 1
mysql> SELECT GET_LOCK('lock2',10);
-> 1
mysql> SELECT RELEASE_LOCK('lock2');
-> 1
mysql> SELECT RELEASE_LOCK('lock1');
-> NULL
```

The second `RELEASE_LOCK()` call returns **NULL** because the lock '*lock1*' was automatically released by the second `GET_LOCK()` call.

Note: If a client attempts to acquire a lock that is already held by another client, it blocks according to the *timeout* argument. If the blocked client terminates, its thread does not die until the lock request times out. This is a known bug.

- `INET_ATON(expr)`

Given the dotted-quad representation of a network address as a string, returns an integer that represents the numeric value of the address. Addresses may be 4- or 8-byte addresses.

```
mysql> SELECT INET_ATON('209.207.224.40');
-> 3520061480
```

The generated number is always in network byte order. For the example just shown, the number is calculated as $209 \times 256^3 + 207 \times 256^2 + 224 \times 256 + 40$.

`INET_ATON()` also understands short-form IP addresses:

```
mysql> SELECT INET_ATON('127.0.0.1'), INET_ATON('127.1');
-> 2130706433, 2130706433
```

Note

When storing values generated by `INET_ATON()`, it is recommended that you use an `INT UNSIGNED` column. If you use a (signed) `INT` column, values corresponding to IP addresses for which the first octet is greater than 127 cannot be stored correctly. See [Section 10.2, “Numeric Types”](#).

- `INET_NTOA(expr)`

Given a numeric network address (4 or 8 byte), returns the dotted-quad representation of the address as a string.

```
mysql> SELECT INET_NTOA(3520061480);
-> '209.207.224.40'
```

- **IS_FREE_LOCK(*str*)**

Checks whether the lock named *str* is free to use (that is, not locked). Returns **1** if the lock is free (no one is using the lock), **0** if the lock is in use, and **NULL** if an error occurs (such as an incorrect argument).

- **IS_USED_LOCK(*str*)**

Checks whether the lock named *str* is in use (that is, locked). If so, it returns the connection identifier of the client that holds the lock. Otherwise, it returns **NULL**.

- **MASTER_POS_WAIT(*log_name*, *log_pos*[, *timeout*])**

This function is useful for control of master/slave synchronization. It blocks until the slave has read and applied all updates up to the specified position in the master log. The return value is the number of log events the slave had to wait for to advance to the specified position. The function returns **NULL** if the slave SQL thread is not started, the slave's master information is not initialized, the arguments are incorrect, or an error occurs. It returns **-1** if the timeout has been exceeded. If the slave SQL thread stops while **MASTER_POS_WAIT()** is waiting, the function returns **NULL**. If the slave is past the specified position, the function returns immediately.

If a *timeout* value is specified, **MASTER_POS_WAIT()** stops waiting when *timeout* seconds have elapsed. *timeout* must be greater than 0; a zero or negative *timeout* means no timeout.

- **NAME_CONST(*name*, *value*)**

Returns the given value. When used to produce a result set column, **NAME_CONST()** causes the column to have the given name.

```
mysql> SELECT NAME_CONST('myname', 14);
+-----+
| myname |
+-----+
|      14 |
+-----+
```

This function was added in MySQL 5.0.12. It is for internal use only. The server uses it when writing statements from stored routines that contain references to local routine variables, as described in [Section 19.4, “Binary Logging of Stored Routines and Triggers”](#). You might see this function in the output from **mysqlbinlog**.

- **RELEASE_LOCK(*str*)**

Releases the lock named by the string *str* that was obtained with **GET_LOCK()**. Returns **1** if the lock was released, **0** if the lock was not established by this thread (in which case the lock is not released), and **NULL** if the named lock did not exist. The lock does not exist if it was never obtained by a call to **GET_LOCK()** or if it has previously been released.

The **DO** statement is convenient to use with **RELEASE_LOCK()**. See [Section 12.2.2, “DO Syntax”](#).

- **SLEEP(*duration*)**

Sleeps (pauses) for the number of seconds given by the *duration* argument, then returns 0. If **SLEEP()** is interrupted, it returns 1. The duration may have a fractional part given in microseconds.

- **UUID()**

Returns a Universal Unique Identifier (UUID) generated according to “DCE 1.1: Remote Procedure Call” (Appendix A) CAE (Common Applications Environment) Specifications published by The Open Group in October 1997 (Document Number C706, <http://www.opengroup.org/public/pubs/catalog/c706.htm>).

A UUID is designed as a number that is globally unique in space and time. Two calls to **UUID()** are expected to generate two different values, even if these calls are performed on two separate computers that are not connected to each other.

A UUID is a 128-bit number represented by a string of five hexadecimal numbers in **aaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee** format:

- The first three numbers are generated from a timestamp.
- The fourth number preserves temporal uniqueness in case the timestamp value loses monotonicity (for example, due to daylight saving time).
- The fifth number is an IEEE 802 node number that provides spatial uniqueness. A random number is substituted if the latter is not available (for example, because the host computer has no Ethernet card, or we do not know how to find the hardware address of an interface on your operating system). In this case, spatial uniqueness cannot be guaranteed. Nevertheless, a collision should have very low probability.

Currently, the MAC address of an interface is taken into account only on FreeBSD and Linux. On other operating systems, MySQL uses a randomly generated 48-bit number.

```
mysql> SELECT UUID();
-> '6ccd780c-baba-1026-9564-0040f4311e29'
```

Note that `UUID()` does not yet work with replication.

- `VALUES(col_name)`

In an `INSERT ... ON DUPLICATE KEY UPDATE` statement, you can use the `VALUES(col_name)` function in the `UPDATE` clause to refer to column values from the `INSERT` portion of the statement. In other words, `VALUES(col_name)` in the `UPDATE` clause refers to the value of `col_name` that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The `VALUES()` function is meaningful only in `INSERT ... ON DUPLICATE KEY UPDATE` statements and returns `NULL` otherwise. [Section 12.2.4.3, “INSERT ... ON DUPLICATE KEY UPDATE Syntax”](#).

```
mysql> INSERT INTO table (a,b,c) VALUES (1,2,3), (4,5,6)
-> ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

11.12. Functions and Modifiers for Use with **GROUP BY** Clauses

11.12.1. **GROUP BY** (Aggregate) Functions

Name	Description
<code>AVG()</code>	Return the average value of the argument
<code>BIT_AND()</code>	Return bitwise and
<code>BIT_OR()</code>	Return bitwise or
<code>BIT_XOR()</code> (v4.1.1)	Return bitwise xor
<code>COUNT(DISTINCT)</code>	Return the count of a number of different values
<code>COUNT()</code>	Return a count of the number of rows returned
<code>GROUP_CONCAT()</code> (v4.1)	Return a concatenated string
<code>MAX()</code>	Return the maximum value
<code>MIN()</code>	Return the minimum value
<code>STD(), STDDEV()</code>	Return the population standard deviation
<code>STDDEV_POP()</code> (v5.0.3)	Return the population standard deviation
<code>STDDEV_SAMP()</code> (v5.0.3)	Return the sample standard deviation
<code>SUM()</code>	Return the sum
<code>VAR_POP()</code> (v5.0.3)	Return the population standard variance
<code>VAR_SAMP()</code> (v5.0.3)	Return the sample variance
<code>VARIANCE()</code> (v4.1)	Return the population standard variance

This section describes group (aggregate) functions that operate on sets of values. Unless otherwise stated, group functions ignore `NULL` values.

If you use a group function in a statement containing no **GROUP BY** clause, it is equivalent to grouping on all rows.

For numeric arguments, the variance and standard deviation functions return a **DOUBLE** value. The **SUM()** and **AVG()** functions return a **DECIMAL** value for exact-value arguments (integer or **DECIMAL**), and a **DOUBLE** value for approximate-value arguments (**FLOAT** or **DOUBLE**).

The **SUM()** and **AVG()** aggregate functions do not work with temporal values. (They convert the values to numbers, losing everything after the first non-numeric character.) To work around this problem, you can convert to numeric units, perform the aggregate operation, and convert back to a temporal value. Examples:

```
SELECT SEC_TO_TIME(SUM(TIME_TO_SEC(time_col))) FROM tbl_name;
SELECT FROM_DAYS(SUM(TO_DAYS(date_col))) FROM tbl_name;
```

Functions such as **SUM()** or **AVG()** that expect a numeric argument cast the argument to a number if necessary. For **SET** or **ENUM** values, the cast operation causes the underlying numeric value to be used.

- **AVG([DISTINCT] *expr*)**

Returns the average value of *expr*. The **DISTINCT** option can be used to return the average of the distinct values of *expr*.

AVG() returns **NULL** if there were no matching rows.

```
mysql> SELECT student_name, AVG(test_score)
->      FROM student
->      GROUP BY student_name;
```

- **BIT_AND(*expr*)**

Returns the bitwise **AND** of all bits in *expr*. The calculation is performed with 64-bit (**BIGINT**) precision.

This function returns **18446744073709551615** if there were no matching rows. (This is the value of an unsigned **BIGINT** value with all bits set to 1.)

- **BIT_OR(*expr*)**

Returns the bitwise **OR** of all bits in *expr*. The calculation is performed with 64-bit (**BIGINT**) precision.

This function returns **0** if there were no matching rows.

- **BIT_XOR(*expr*)**

Returns the bitwise **XOR** of all bits in *expr*. The calculation is performed with 64-bit (**BIGINT**) precision.

This function returns **0** if there were no matching rows.

- **COUNT(*expr*)**

Returns a count of the number of non-**NULL** values of *expr* in the rows retrieved by a **SELECT** statement. The result is a **BIGINT** value.

COUNT() returns **0** if there were no matching rows.

```
mysql> SELECT student.student_name, COUNT(*)
->      FROM student, course
->      WHERE student.student_id=course.student_id
->      GROUP BY student_name;
```

COUNT(*) is somewhat different in that it returns a count of the number of rows retrieved, whether or not they contain **NULL** values.

COUNT(*) is optimized to return very quickly if the **SELECT** retrieves from one table, no other columns are retrieved, and there is no **WHERE** clause. For example:

```
mysql> SELECT COUNT(*) FROM student;
```

This optimization applies only to **MyISAM** tables only, because an exact row count is stored for this storage engine and can be accessed very quickly. For transactional storage engines such as **InnoDB**, storing an exact row count is more problematic because multiple transactions may be occurring, each of which may affect the count.

- **COUNT(DISTINCT *expr*, [*expr*...])**

Returns a count of the number of different non-**NULL** values.

COUNT(DISTINCT) returns 0 if there were no matching rows.

```
mysql> SELECT COUNT(DISTINCT results) FROM student;
```

In MySQL, you can obtain the number of distinct expression combinations that do not contain **NULL** by giving a list of expressions. In standard SQL, you would have to do a concatenation of all expressions inside **COUNT(DISTINCT ...)**.

- **GROUP_CONCAT(*expr*)**

This function returns a string result with the concatenated non-**NULL** values from a group. It returns **NULL** if there are no non-**NULL** values. The full syntax is as follows:

```
GROUP_CONCAT([DISTINCT] expr [, expr ...]
             [ORDER BY {unsigned_integer | col_name | expr}
              [ASC | DESC] [, col_name ...]]
             [SEPARATOR str_val])
```

```
mysql> SELECT student_name,
->        GROUP_CONCAT(test_score)
->        FROM student
->        GROUP BY student_name;
```

Or:

```
mysql> SELECT student_name,
->        GROUP_CONCAT(DISTINCT test_score
->                      ORDER BY test_score DESC SEPARATOR ' ')
->        FROM student
->        GROUP BY student_name;
```

In MySQL, you can get the concatenated values of expression combinations. You can eliminate duplicate values by using **DISTINCT**. If you want to sort values in the result, you should use **ORDER BY** clause. To sort in reverse order, add the **DESC** (descending) keyword to the name of the column you are sorting by in the **ORDER BY** clause. The default is ascending order; this may be specified explicitly using the **ASC** keyword. **SEPARATOR** is followed by the string value that should be inserted between values of result. The default is a comma (','). You can eliminate the separator altogether by specifying **SEPARATOR ''**.

The result is truncated to the maximum length that is given by the **group_concat_max_len** system variable, which has a default value of 1024. The value can be set higher, although the maximum effective length of the return value is constrained by the value of **max_allowed_packet**. The syntax to change the value of **group_concat_max_len** at runtime is as follows, where *val* is an unsigned integer:

```
SET [SESSION | GLOBAL] group_concat_max_len = val;
```

The type returned by **GROUP_CONCAT()** is always **VARCHAR** unless **group_concat_max_len** is greater than 512, in which case, it returns a **BLOB**.

See also **CONCAT()** and **CONCAT_WS()**: [Section 11.4, “String Functions”](#).

- **MIN([DISTINCT] *expr*), MAX([DISTINCT] *expr*)**

Returns the minimum or maximum value of *expr*. **MIN()** and **MAX()** may take a string argument; in such cases they return the minimum or maximum string value. See [Section 6.4.5, “How MySQL Uses Indexes”](#). The **DISTINCT** keyword can be used to find the minimum or maximum of the distinct values of *expr*, however, this produces the same result as omitting **DISTINCT**.

MIN() and **MAX()** return **NULL** if there were no matching rows.

```
mysql> SELECT student_name, MIN(test_score), MAX(test_score)
->        FROM student
```

```
-> GROUP BY student_name;
```

For `MIN()`, `MAX()`, and other aggregate functions, MySQL currently compares `ENUM` and `SET` columns by their string value rather than by the string's relative position in the set. This differs from how `ORDER BY` compares them. This is expected to be rectified in a future MySQL release.

- `STD(expr) STDDEV(expr)`

Returns the population standard deviation of *expr*. This is an extension to standard SQL. The `STDDEV()` form of this function is provided for compatibility with Oracle. The standard SQL function `STDDEV_POP()` can be used instead.

These functions return `NULL` if there were no matching rows.

- `STDDEV_POP(expr)`

Returns the population standard deviation of *expr* (the square root of `VAR_POP()`). You can also use `STD()` or `STDDEV()`, which are equivalent but not standard SQL.

`STDDEV_POP()` returns `NULL` if there were no matching rows.

- `STDDEV_SAMP(expr)`

Returns the sample standard deviation of *expr* (the square root of `VAR_SAMP()`).

`STDDEV_SAMP()` returns `NULL` if there were no matching rows.

- `SUM([DISTINCT] expr)`

Returns the sum of *expr*. If the return set has no rows, `SUM()` returns `NULL`. The `DISTINCT` keyword can be used in MySQL 5.1 to sum only the distinct values of *expr*.

`SUM()` returns `NULL` if there were no matching rows.

- `VAR_POP(expr)`

Returns the population standard variance of *expr*. It considers rows as the whole population, not as a sample, so it has the number of rows as the denominator. You can also use `VARIANCE()`, which is equivalent but is not standard SQL.

`VAR_POP()` returns `NULL` if there were no matching rows.

- `VAR_SAMP(expr)`

Returns the sample variance of *expr*. That is, the denominator is the number of rows minus one.

`VAR_SAMP()` returns `NULL` if there were no matching rows.

- `VARIANCE(expr)`

Returns the population standard variance of *expr*. This is an extension to standard SQL. The standard SQL function `VAR_POP()` can be used instead.

`VARIANCE()` returns `NULL` if there were no matching rows.

11.12.2. GROUP BY Modifiers

The `GROUP BY` clause allows a `WITH ROLLUP` modifier that causes extra rows to be added to the summary output. These rows represent higher-level (or super-aggregate) summary operations. `ROLLUP` thus allows you to answer questions at multiple levels of analysis with a single query. It can be used, for example, to provide support for OLAP (Online Analytical Processing) operations.

Suppose that a table named `sales` has `year`, `country`, `product`, and `profit` columns for recording sales profitability:

```
CREATE TABLE sales
(
  year      INT NOT NULL,
  country   VARCHAR(20) NOT NULL,
  product   VARCHAR(32) NOT NULL,
```

```
profit INT
);
```

The table's contents can be summarized per year with a simple **GROUP BY** like this:

```
mysql> SELECT year, SUM(profit) FROM sales GROUP BY year;
+-----+-----+
| year | SUM(profit) |
+-----+-----+
| 2000 |          4525 |
| 2001 |          3010 |
+-----+-----+
```

This output shows the total profit for each year, but if you also want to determine the total profit summed over all years, you must add up the individual values yourself or run an additional query.

Or you can use **ROLLUP**, which provides both levels of analysis with a single query. Adding a **WITH ROLLUP** modifier to the **GROUP BY** clause causes the query to produce another row that shows the grand total over all year values:

```
mysql> SELECT year, SUM(profit) FROM sales GROUP BY year WITH ROLLUP;
+-----+-----+
| year | SUM(profit) |
+-----+-----+
| 2000 |          4525 |
| 2001 |          3010 |
| NULL |          7535 |
+-----+-----+
```

The grand total super-aggregate line is identified by the value **NULL** in the **year** column.

ROLLUP has a more complex effect when there are multiple **GROUP BY** columns. In this case, each time there is a “break” (change in value) in any but the last grouping column, the query produces an extra super-aggregate summary row.

For example, without **ROLLUP**, a summary on the **sales** table based on **year**, **country**, and **product** might look like this:

```
mysql> SELECT year, country, product, SUM(profit)
-> FROM sales
-> GROUP BY year, country, product;
+-----+-----+-----+-----+
| year | country | product | SUM(profit) |
+-----+-----+-----+-----+
| 2000 | Finland | Computer |          1500 |
| 2000 | Finland | Phone   |           100 |
| 2000 | India   | Calculator |          150 |
| 2000 | India   | Computer |         1200 |
| 2000 | USA     | Calculator |           75 |
| 2000 | USA     | Computer |         1500 |
| 2001 | Finland | Phone   |           10 |
| 2001 | USA     | Calculator |           50 |
| 2001 | USA     | Computer |         2700 |
| 2001 | USA     | TV       |           250 |
+-----+-----+-----+-----+
```

The output indicates summary values only at the year/country/product level of analysis. When **ROLLUP** is added, the query produces several extra rows:

```
mysql> SELECT year, country, product, SUM(profit)
-> FROM sales
-> GROUP BY year, country, product WITH ROLLUP;
+-----+-----+-----+-----+
| year | country | product | SUM(profit) |
+-----+-----+-----+-----+
| 2000 | Finland | Computer |          1500 |
| 2000 | Finland | Phone   |           100 |
| 2000 | Finland | NULL    |          1600 |
| 2000 | India   | Calculator |          150 |
| 2000 | India   | Computer |         1200 |
| 2000 | India   | NULL    |         1350 |
| 2000 | USA     | Calculator |           75 |
| 2000 | USA     | Computer |         1500 |
| 2000 | USA     | NULL    |         1575 |
| 2000 | NULL    | NULL    |          4525 |
| 2001 | Finland | Phone   |           10 |
| 2001 | Finland | NULL    |           10 |
| 2001 | USA     | Calculator |           50 |
| 2001 | USA     | Computer |         2700 |
| 2001 | USA     | TV       |           250 |
| 2001 | USA     | NULL    |         3000 |
+-----+-----+-----+-----+
```

2001	NULL	NULL	3010
NULL	NULL	NULL	7535

For this query, adding **ROLLUP** causes the output to include summary information at four levels of analysis, not just one. Here's how to interpret the **ROLLUP** output:

- Following each set of product rows for a given year and country, an extra summary row is produced showing the total for all products. These rows have the **product** column set to **NULL**.
- Following each set of rows for a given year, an extra summary row is produced showing the total for all countries and products. These rows have the **country** and **products** columns set to **NULL**.
- Finally, following all other rows, an extra summary row is produced showing the grand total for all years, countries, and products. This row has the **year**, **country**, and **products** columns set to **NULL**.

Other Considerations When using **ROLLUP**

The following items list some behaviors specific to the MySQL implementation of **ROLLUP**:

When you use **ROLLUP**, you cannot also use an **ORDER BY** clause to sort the results. In other words, **ROLLUP** and **ORDER BY** are mutually exclusive. However, you still have some control over sort order. **GROUP BY** in MySQL sorts results, and you can use explicit **ASC** and **DESC** keywords with columns named in the **GROUP BY** list to specify sort order for individual columns. (The higher-level summary rows added by **ROLLUP** still appear after the rows from which they are calculated, regardless of the sort order.)

LIMIT can be used to restrict the number of rows returned to the client. **LIMIT** is applied after **ROLLUP**, so the limit applies against the extra rows added by **ROLLUP**. For example:

```
mysql> SELECT year, country, product, SUM(profit)
-> FROM sales
-> GROUP BY year, country, product WITH ROLLUP
-> LIMIT 5;
```

year	country	product	SUM(profit)
2000	Finland	Computer	1500
2000	Finland	Phone	100
2000	Finland	NULL	1600
2000	India	Calculator	150
2000	India	Computer	1200

Using **LIMIT** with **ROLLUP** may produce results that are more difficult to interpret, because you have less context for understanding the super-aggregate rows.

The **NULL** indicators in each super-aggregate row are produced when the row is sent to the client. The server looks at the columns named in the **GROUP BY** clause following the leftmost one that has changed value. For any column in the result set with a name that is a lexical match to any of those names, its value is set to **NULL**. (If you specify grouping columns by column number, the server identifies which columns to set to **NULL** by number.)

Because the **NULL** values in the super-aggregate rows are placed into the result set at such a late stage in query processing, you cannot test them as **NULL** values within the query itself. For example, you cannot add **HAVING product IS NULL** to the query to eliminate from the output all but the super-aggregate rows.

On the other hand, the **NULL** values do appear as **NULL** on the client side and can be tested as such using any MySQL client programming interface.

11.12.3. **GROUP BY** and **HAVING** with Hidden Fields

MySQL extends the use of **GROUP BY** so that you can use non-aggregated columns or calculations in the **SELECT** list that do not appear in the **GROUP BY** clause. You can use this feature to get better performance by avoiding unnecessary column sorting and grouping. For example, you do not need to group on **customer.name** in the following query:

```
SELECT order.custid, customer.name, MAX(payments)
FROM order, customer
WHERE order.custid = customer.custid
GROUP BY order.custid;
```

In standard SQL, you would have to add `customer.name` to the `GROUP BY` clause. In MySQL, the name is redundant.

Do *not* use this feature if the columns you omit from the `GROUP BY` part are not constant in the group. The server is free to return any value from the group, so the results are indeterminate unless all values are the same.

A similar MySQL extension applies to the `HAVING` clause. The SQL standard does not allow the `HAVING` clause to name any column that is not found in the `GROUP BY` clause if it is not enclosed in an aggregate function. MySQL allows the use of such columns to simplify calculations. This extension assumes that the non-grouped columns will have the same group-wise values. Otherwise, the result is indeterminate.

If the `ONLY_FULL_GROUP_BY` SQL mode is enabled, the MySQL extension to `GROUP BY` does not apply. That is, columns not named in the `GROUP BY` clause cannot be used in the `SELECT` list or `HAVING` clause if not used in an aggregate function.

The select list extension also applies to `ORDER BY`. That is, you can use non-aggregated columns or calculations in the `ORDER BY` clause that do not appear in the `GROUP BY` clause. This extension does not apply if the `ONLY_FULL_GROUP_BY` SQL mode is enabled.

In some cases, you can use `MIN()` and `MAX()` to obtain a specific column value even if it isn't unique. The following gives the value of `column` from the row containing the smallest value in the `sort` column:

```
SUBSTR(MIN(CONCAT(RPAD(sort,6,' '),column)),7)
```

See [Section 3.6.4, “The Rows Holding the Group-wise Maximum of a Certain Field”](#).

Note that if you are trying to follow standard SQL, you can't use expressions in `GROUP BY` clauses. You can work around this limitation by using an alias for the expression:

```
SELECT id,FLOOR(value/100) AS val
FROM   tbl_name
GROUP BY id, val;
```

MySQL does allow expressions in `GROUP BY` clauses. For example:

```
SELECT id,FLOOR(value/100)
FROM   tbl_name
GROUP BY id, FLOOR(value/100);
```

Chapter 12. SQL Statement Syntax

This chapter describes the syntax for most of the SQL statements supported by MySQL. Additional statement descriptions can be found in the following chapters:

- The **EXPLAIN** statement is discussed in [Chapter 6, Optimization](#).
- Statements for writing stored routines are covered in [Chapter 19, Stored Procedures and Functions](#).
- Statements for writing triggers are covered in [Chapter 20, Triggers](#).
- View-related statements are covered in [Chapter 22, Views](#).
- Statements for scheduling events are covered in [Chapter 21, Event Scheduler](#).

12.1. Data Definition Statements

12.1.1. ALTER DATABASE Syntax

```
ALTER {DATABASE | SCHEMA} [db_name]
    alter_specification ...

alter_specification:
    [DEFAULT] CHARACTER SET charset_name
  | [DEFAULT] COLLATE collation_name
```

ALTER DATABASE enables you to change the overall characteristics of a database. These characteristics are stored in the **db.opt** file in the database directory. To use **ALTER DATABASE**, you need the **ALTER** privilege on the database. **ALTER SCHEMA** is a synonym for **ALTER DATABASE**.

The **CHARACTER SET** clause changes the default database character set. The **COLLATE** clause changes the default database collation. [Chapter 9, Character Set Support](#), discusses character set and collation names.

The database name can be omitted, in which case the statement applies to the default database.

MySQL Enterprise

In a production environment, alteration of a database is not a common occurrence and may indicate a security breach. Advisors provided as part of the MySQL Enterprise Monitor automatically alert you when data definition statements are issued. For more information see, <http://www.mysql.com/products/enterprise/advisors.html>.

12.1.2. ALTER LOGFILE GROUP Syntax

```
ALTER LOGFILE GROUP logfile_group
    ADD UNDOFILE 'file'
    [INITIAL_SIZE [=] size]
    [WAIT]
    ENGINE [=] engine
```

This statement adds an **UNDO** file named **'file'** to an existing log file group **logfile_group**. An **ALTER LOGFILE GROUP** statement has one and only one **ADD UNDOFILE** clause. No **DROP UNDOFILE** clause is supported.

The optional **INITIAL_SIZE** parameter sets the **UNDO** file's initial size in bytes; if not specified, the initial size default to **128M** (128 megabytes). You may optionally follow **size** with a one-letter abbreviation for an order of magnitude, similar to those used in **my.cnf**. Generally, this is one of the letters **M** (for megabytes) or **G** (for gigabytes).

WAIT is parsed but otherwise ignored, and so has no effect in MySQL 5.1. It is intended for future expansion.

The **ENGINE** parameter (required) determines the storage engine which is used by this log file group, with **engine** being the name of the storage engine. In MySQL 5.1, the only accepted values for **engine** are **NDB** and **NDBCLUSTER**.

Here is an example, which assumes that the log file group **lg_3** has already been created using **CREATE LOGFILE GROUP** (see [Section 12.1.8, "CREATE LOGFILE GROUP Syntax"](#)):

```
ALTER LOGFILE GROUP lg_3
ADD UNDOFILE 'undo_10.dat'
INITIAL_SIZE=32M
ENGINE=NDB;
```

When **ALTER LOGFILE GROUP** is used with **ENGINE = NDB**, an **UNDO** log file is created on each Cluster data node. You can verify that the **UNDO** files were created and obtain information about them by querying the **INFORMATION_SCHEMA.FILES** table. For example:

```
mysql> SELECT FILE_NAME, LOGFILE_GROUP_NUMBER, EXTRA
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE LOGFILE_GROUP_NAME = 'lg_3';
```

FILE_NAME	LOGFILE_GROUP_NUMBER	EXTRA
newdata.dat	0	CLUSTER_NODE=3
newdata.dat	0	CLUSTER_NODE=4
undo_10.dat	11	CLUSTER_NODE=3
undo_10.dat	11	CLUSTER_NODE=4

4 rows in set (0.01 sec)

(See [Section 23.21](#), “The **INFORMATION_SCHEMA.FILES** Table”.)

ALTER LOGFILE GROUP was added in MySQL 5.1.6. In MySQL 5.1, it is useful only with Disk Data storage for MySQL Cluster. See [Section 16.11](#), “MySQL Cluster Disk Data Tables”.

12.1.3. ALTER SERVER Syntax

```
ALTER SERVER server_name
OPTIONS (option ...)
```

Alters the server information for *server_name*, adjusting the specified options as per the **CREATE SERVER** command. See [Section 12.1.9](#), “**CREATE SERVER Syntax**”. The corresponding fields in the **mysql.servers** table are updated accordingly. This statement requires the **SUPER** privilege.

For example, to update the **USER** option:

```
ALTER SERVER s OPTIONS (USER 'sally');
```

ALTER SERVER does not cause an automatic commit.

12.1.4. ALTER TABLE Syntax

```
ALTER [IGNORE] TABLE tbl_name
alter_specification [, alter_specification] ...

alter_specification:
column_definition [FIRST | AFTER col_name]
| ADD [COLUMN] (column_definition,...)
| ADD {INDEX|KEY} [index_name] [index_type] (index_col_name,...)
| ADD [CONSTRAINT [symbol]]
    PRIMARY KEY [index_type] (index_col_name,...)
| ADD [CONSTRAINT [symbol]]
    UNIQUE [INDEX|KEY] [index_name] [index_type] (index_col_name,...)
| ADD FULLTEXT [INDEX|KEY] [index_name] (index_col_name,...)
    [WITH PARSER parser_name]
| ADD SPATIAL [INDEX|KEY] [index_name] (index_col_name,...)
| ADD [CONSTRAINT [symbol]]
    FOREIGN KEY [index_name] (index_col_name,...)
    [reference_definition]
| ALTER [COLUMN] col_name {SET DEFAULT literal | DROP DEFAULT}
| CHANGE [COLUMN] old_col_name column_definition
    [FIRST|AFTER col_name]
| MODIFY [COLUMN] column_definition [FIRST | AFTER col_name]
| DROP [COLUMN] col_name
| DROP PRIMARY KEY
| DROP {INDEX|KEY} index_name
| DROP FOREIGN KEY fk_symbol
| DISABLE KEYS
| ENABLE KEYS
| RENAME [TO] new_tbl_name
| ORDER BY col_name [, col_name] ...
| CONVERT TO CHARACTER SET charset_name [COLLATE collation_name]
```

```

[DEFAULT] CHARACTER SET charset_name [COLLATE collation_name]
DISCARD TABLESPACE
IMPORT TABLESPACE
PARTITION BY partition_options
ADD PARTITION (partition_definition)
DROP PARTITION partition_names
COALESCE PARTITION number
REORGANIZE PARTITION partition_names INTO (partition_definitions)
ANALYZE PARTITION partition_names
CHECK PARTITION partition_names
OPTIMIZE PARTITION partition_names
REBUILD PARTITION partition_names
REPAIR PARTITION partition_names
REMOVE PARTITIONING

index_col_name:
    col_name [(length)] [ASC | DESC]

index_type:
    USING {BTREE | HASH}

```

ALTER TABLE enables you to change the structure of an existing table. For example, you can add or delete columns, create or destroy indexes, change the type of existing columns, or rename columns or the table itself. You can also change the comment for the table and type of the table.

The syntax for many of the allowable alterations is similar to clauses of the **CREATE TABLE** statement. See [Section 12.1.10, “CREATE TABLE Syntax”](#), for more information.

Some operations may result in warnings if attempted on a table for which the storage engine does not support the operation. These warnings can be displayed with **SHOW WARNINGS**. See [Section 12.5.4.32, “SHOW WARNINGS Syntax”](#).

In most cases, **ALTER TABLE** works by making a temporary copy of the original table. The alteration is performed on the copy, and then the original table is deleted and the new one is renamed. While **ALTER TABLE** is executing, the original table is readable by other clients. Updates and writes to the table are stalled until the new table is ready, and then are automatically redirected to the new table without any failed updates.

In some cases, no temporary table is necessary:

- If you use **ALTER TABLE *tbl_name* RENAME TO *new_tbl_name*** without any other options, MySQL simply renames any files that correspond to the table *tbl_name*. (You can also use the **RENAME TABLE** statement to rename tables. See [Section 12.1.19, “RENAME TABLE Syntax”](#).) Any privileges granted specifically for the renamed table are not migrated to the new name. They must be changed manually.
- **ALTER TABLE ... ADD PARTITION** creates no temporary table except for MySQL Cluster. **ADD** or **DROP** operations for **RANGE** or **LIST** partitions are immediate operations or nearly so. **ADD** or **COALESCE** operations for **HASH** or **KEY** partitions copy data between changed partitions; unless **LINEAR HASH/KEY** was used, this is much the same as creating a new table (although the operation is done partition by partition). **REORGANIZE** operations copy only changed partitions and do not touch unchanged ones.

If other cases, MySQL creates a temporary table, even if the data wouldn't strictly need to be copied (such as when you change the name of a column). For **MyISAM** tables, you can speed up the index re-creation operation (which is the slowest part of the alteration process) by setting the **myisam_sort_buffer_size** system variable to a high value.

- To use **ALTER TABLE**, you need **ALTER**, **INSERT**, and **CREATE** privileges for the table.
- **IGNORE** is a MySQL extension to standard SQL. It controls how **ALTER TABLE** works if there are duplicates on unique keys in the new table or if warnings occur when strict mode is enabled. If **IGNORE** is not specified, the copy is aborted and rolled back if duplicate-key errors occur. If **IGNORE** is specified, only the first row is used of rows with duplicates on a unique key. The other conflicting rows are deleted. Incorrect values are truncated to the closest matching acceptable value.
- *table_option* signifies a table option of the kind that can be used in the **CREATE TABLE** statement. ([Section 12.1.10, “CREATE TABLE Syntax”](#), lists all table options.) This includes options such as **ENGINE**, **AUTO_INCREMENT**, and **AVG_ROW_LENGTH**. However, **ALTER TABLE** ignores the **DATA DIRECTORY** and **INDEX DIRECTORY** table options.

For example, to convert a table to be an **InnoDB** table, use this statement:

```
ALTER TABLE t1 ENGINE = InnoDB;
```

The outcome of attempting to change a table's storage engine is affected by whether the desired storage engine is available and the

setting of the `NO_ENGINE_SUBSTITUTION` SQL mode, as described in [Section 5.2.6, “SQL Modes”](#).

As of MySQL 5.1.11, to prevent inadvertent loss of data, `ALTER TABLE` cannot be used to change the storage engine of a table to `MERGE` or `BLACKHOLE`.

To change the value of the `AUTO_INCREMENT` counter to be used for new rows, do this:

```
ALTER TABLE t2 AUTO_INCREMENT = value;
```

You cannot reset the counter to a value less than or equal to any that have already been used. For `MyISAM`, if the value is less than or equal to the maximum value currently in the `AUTO_INCREMENT` column, the value is reset to the current maximum plus one. For `InnoDB`, *if the value is less than the current maximum value in the column, no error message is given and the current sequence value is not changed.*

- You can issue multiple `ADD`, `ALTER`, `DROP`, and `CHANGE` clauses in a single `ALTER TABLE` statement, separated by commas. This is a MySQL extension to standard SQL, which allows only one of each clause per `ALTER TABLE` statement. For example, to drop multiple columns in a single statement, do this:

```
ALTER TABLE t2 DROP COLUMN c, DROP COLUMN d;
```

- `CHANGE col_name`, `DROP col_name`, and `DROP INDEX` are MySQL extensions to standard SQL.
- `MODIFY` is an Oracle extension to `ALTER TABLE`.
- The word `COLUMN` is optional and can be omitted.
- `column_definition` clauses use the same syntax for `ADD` and `CHANGE` as for `CREATE TABLE`. Note that this syntax includes the column name, not just its data type. See [Section 12.1.10, “CREATE TABLE Syntax”](#).
- You can rename a column using a `CHANGE old_col_name column_definition` clause. To do so, specify the old and new column names and the type that the column currently has. For example, to rename an `INTEGER` column from `a` to `b`, you can do this:

```
ALTER TABLE t1 CHANGE a b INTEGER;
```

If you want to change a column's type but not the name, `CHANGE` syntax still requires an old and new column name, even if they are the same. For example:

```
ALTER TABLE t1 CHANGE b b BIGINT NOT NULL;
```

You can also use `MODIFY` to change a column's type without renaming it:

```
ALTER TABLE t1 MODIFY b BIGINT NOT NULL;
```

- If you use `CHANGE` or `MODIFY` to shorten a column for which an index exists on the column, and the resulting column length is less than the index length, MySQL shortens the index automatically.
- When you change a data type using `CHANGE` or `MODIFY`, MySQL tries to convert existing column values to the new type as well as possible.
- To add a column at a specific position within a table row, use `FIRST` or `AFTER col_name`. The default is to add the column last. You can also use `FIRST` and `AFTER` in `CHANGE` or `MODIFY` operations.
- `ALTER ... SET DEFAULT` or `ALTER ... DROP DEFAULT` specify a new default value for a column or remove the old default value, respectively. If the old default is removed and the column can be `NULL`, the new default is `NULL`. If the column cannot be `NULL`, MySQL assigns a default value, as described in [Section 10.1.4, “Data Type Default Values”](#).
- `DROP INDEX` removes an index. This is a MySQL extension to standard SQL. See [Section 12.1.13, “DROP INDEX Syntax”](#).
- If columns are dropped from a table, the columns are also removed from any index of which they are a part. If all columns that make up an index are dropped, the index is dropped as well.
- If a table contains only one column, the column cannot be dropped. If what you intend is to remove the table, use `DROP TABLE` in-

stead.

- **DROP PRIMARY KEY** drops the primary index.

Note

In older versions of MySQL, if no primary index existed, **DROP PRIMARY KEY** would drop the first **UNIQUE** index in the table. This is not the case in MySQL 5.1, where trying to use **DROP PRIMARY KEY** on a table with no primary key results in an error.

If you add a **UNIQUE INDEX** or **PRIMARY KEY** to a table, it is stored before any non-unique index so that MySQL can detect duplicate keys as early as possible.

- Some storage engines allow you to specify an index type when creating an index. The syntax for the *index_type* specifier is **USING type_name**. Before MySQL 5.1.10, **USING** can be given only before the index column list. As of 5.1.10, the preferred position is after the column list. Use of the option before the column list will no longer be recognized as of MySQL 5.3.
- After an **ALTER TABLE** statement, it may be necessary to run **ANALYZE TABLE** to update index cardinality information. See [Section 12.5.4.18, “SHOW INDEX Syntax”](#).
- **ORDER BY** enables you to create the new table with the rows in a specific order. Note that the table does not remain in this order after inserts and deletes. This option is useful primarily when you know that you are mostly to query the rows in a certain order most of the time. By using this option after major changes to the table, you might be able to get higher performance. In some cases, it might make sorting easier for MySQL if the table is in order by the column that you want to order it by later.

ORDER BY syntax allows for one or more column names to be specified for sorting, each of which optionally can be followed by **ASC** or **DESC** to indicate ascending or descending sort order, respectively. The default is ascending order. Only column names are allowed as sort criteria; arbitrary expressions are not allowed.

- If you use **ALTER TABLE** on a **MyISAM** table, all non-unique indexes are created in a separate batch (as for **REPAIR TABLE**). This should make **ALTER TABLE** much faster when you have many indexes.

This feature can be activated explicitly. **ALTER TABLE ... DISABLE KEYS** tells MySQL to stop updating non-unique indexes for a **MyISAM** table. **ALTER TABLE ... ENABLE KEYS** then should be used to re-create missing indexes. MySQL does this with a special algorithm that is much faster than inserting keys one by one, so disabling keys before performing bulk insert operations should give a considerable speedup. Using **ALTER TABLE ... DISABLE KEYS** requires the **INDEX** privilege in addition to the privileges mentioned earlier.

While the non-unique indexes are disabled, they are ignored for statements such as **SELECT** and **EXPLAIN** that otherwise would use them.

ENABLE KEYS and **DISABLE KEYS** were not supported for partitioned tables prior to MySQL 5.1.11. ([Bug#19502](#))

- If **ALTER TABLE** for an **InnoDB** table results in changes to column values (for example, because a column is truncated), **InnoDB**'s **FOREIGN KEY** constraint checks do not notice possible violations caused by changing the values.
- The **FOREIGN KEY** and **REFERENCES** clauses are supported by the **InnoDB** storage engine, which implements **ADD [CONSTRAINT [symbol]] FOREIGN KEY (...) REFERENCES ... (...)**. See [Section 13.5.6.4, “FOREIGN KEY Constraints”](#). For other storage engines, the clauses are parsed but ignored. The **CHECK** clause is parsed but ignored by all storage engines. See [Section 12.1.10, “CREATE TABLE Syntax”](#). The reason for accepting but ignoring syntax clauses is for compatibility, to make it easier to port code from other SQL servers, and to run applications that create tables with references. See [Section 1.9.5, “MySQL Differences from Standard SQL”](#).

You cannot add a foreign key and drop a foreign key in separate clauses of a single **ALTER TABLE** statement. You must use separate statements.

Important

The inline **REFERENCES** specifications where the references are defined as part of the column specification are silently ignored by **InnoDB**. **InnoDB** only accepts **REFERENCES** clauses when specified as part of a separate **FOREIGN KEY** specification.

- **InnoDB** supports the use of **ALTER TABLE** to drop foreign keys:

```
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```

You cannot add a foreign key and drop a foreign key in separate clauses of a single **ALTER TABLE** statement. You must use separate statements.

For more information, see [Section 13.5.6.4, “FOREIGN KEY Constraints”](#).

- Pending **INSERT DELAYED** statements are lost if a table is write locked and **ALTER TABLE** is used to modify the table structure.
- If you want to change the table default character set and all character columns (**CHAR**, **VARCHAR**, **TEXT**) to a new character set, use a statement like this:

```
ALTER TABLE tbl_name CONVERT TO CHARACTER SET charset_name;
```

Warning

The preceding operation converts column values between the character sets. This is *not* what you want if you have a column in one character set (like **latin1**) but the stored values actually use some other, incompatible character set (like **utf8**). In this case, you have to do the following for each such column:

```
ALTER TABLE t1 CHANGE c1 c1 BLOB;
ALTER TABLE t1 CHANGE c1 c1 TEXT CHARACTER SET utf8;
```

The reason this works is that there is no conversion when you convert to or from **BLOB** columns.

If you specify **CONVERT TO CHARACTER SET binary**, the **CHAR**, **VARCHAR**, and **TEXT** columns are converted to their corresponding binary string types (**BINARY**, **VARBINARY**, **BLOB**). This means that the columns no longer will have a character set and a subsequent **CONVERT TO** operation will not apply to them.

To change only the *default* character set for a table, use this statement:

```
ALTER TABLE tbl_name DEFAULT CHARACTER SET charset_name;
```

The word **DEFAULT** is optional. The default character set is the character set that is used if you do not specify the character set for a new column which you add to a table (for example, with **ALTER TABLE ... ADD column**).

- For an **InnoDB** table that is created with its own tablespace in an **.ibd** file, that file can be discarded and imported. To discard the **.ibd** file, use this statement:

```
ALTER TABLE tbl_name DISCARD TABLESPACE;
```

This deletes the current **.ibd** file, so be sure that you have a backup first. Attempting to access the table while the tablespace file is discarded results in an error.

To import the backup **.ibd** file back into the table, copy it into the database directory, and then issue this statement:

```
ALTER TABLE tbl_name IMPORT TABLESPACE;
```

See [Section 13.5.3.1, “Using Per-Table Tablespaces”](#).

- A number of partitioning-related extensions to **ALTER TABLE** were added in MySQL 5.1.5. These can be used with partitioned tables for repartitioning, for adding, dropping, merging, and splitting partitions, and for performing partitioning maintenance.

Simply using a *partition_options* clause with **ALTER TABLE** on a partitioned table repartitions the table according to the partitioning scheme defined by the *partition_options*. This clause always begins with **PARTITION BY**, and follows the same syntax and other rules as apply to the *partition_options* clause for **CREATE TABLE** (see [Section 12.1.10, “CREATE TABLE Syntax”](#), for more detailed information), and can also be used to partition an existing table that is not already partitioned. For example, consider a (non-partitioned) table defined as shown here:

```
CREATE TABLE t1 (
  id INT,
  year_col INT
);
```

This table can be partitioned by **HASH**, using the **id** column as the partitioning key, into 8 partitions by means of this statement:

```
ALTER TABLE t1
PARTITION BY HASH(id)
PARTITIONS 8;
```

The table that results from using an `ALTER TABLE ... PARTITION BY` statement must follow the same rules as one created using `CREATE TABLE ... PARTITION BY`. This includes the rules governing the relationship between any unique keys (including any primary key) that the table might have, and the column or columns used in the partitioning expression, as discussed in [Partitioning Limitations: Partitioning Keys and Unique Keys](#). The `CREATE TABLE ... PARTITION BY` rules for specifying the number of partitions also apply to `ALTER TABLE ... PARTITION BY`.

`ALTER TABLE ... PARTITION BY` became available in MySQL 5.1.6.

The *partition_definition* clause for `ALTER TABLE ADD PARTITION` supports the same options as the clause of the same name does for the `CREATE TABLE` statement clause of the same name. (See [Section 12.1.10, “CREATE TABLE Syntax”](#), for the syntax and description.) Suppose that you have the partitioned table created as shown here:

```
CREATE TABLE t1 (
  id INT,
  year_col INT
)
PARTITION BY RANGE (year_col) (
  PARTITION p0 VALUES LESS THAN (1991),
  PARTITION p1 VALUES LESS THAN (1995),
  PARTITION p2 VALUES LESS THAN (1999)
);
```

You can add a new partition `p3` to this table for storing values less than `2002` as follows:

```
ALTER TABLE t1 ADD PARTITION (PARTITION p3 VALUES LESS THAN (2002));
```

`DROP PARTITION` can be used to drop one or more `RANGE` or `LIST` partitions. This statement cannot be used with `HASH` or `KEY` partitions; instead, use `COALESCE PARTITION` (see below). Any data that was stored in the dropped partitions named in the *partition_names* list is discarded. For example, given the table `t1` defined previously, you can drop the partitions named `p0` and `p1` as shown here:

```
ALTER TABLE t1 DROP PARTITION p0, p1;
```

Note that `DROP PARTITION` does not work with tables that use the `NDB Cluster` storage engine. See [Section 17.3.1, “Management of RANGE and LIST Partitions”](#), and [Section 16.13, “Known Limitations of MySQL Cluster”](#).

`ADD PARTITION` and `DROP PARTITION` do not currently support `IF [NOT] EXISTS`. It is also not possible to rename a partition or a partitioned table. Instead, if you wish to rename a partition, you must drop and re-create the partition; if you wish to rename a partitioned table, you must instead drop all partitions, rename the table, and then add back the partitions that were dropped.

`COALESCE PARTITION` can be used with a table that is partitioned by `HASH` or `KEY` to reduce the number of partitions by *number*. Suppose that you have created table `t2` using the following definition:

```
CREATE TABLE t2 (
  name VARCHAR (30),
  started DATE
)
PARTITION BY HASH( YEAR(started) )
PARTITIONS 6;
```

You can reduce the number of partitions used by `t2` from 6 to 4 using the following statement:

```
ALTER TABLE t2 COALESCE PARTITION 2;
```

The data contained in the last *number* partitions will be merged into the remaining partitions. In this case, partitions 4 and 5 will be merged into the first 4 partitions (the partitions numbered 0, 1, 2, and 3).

To change some but not all the partitions used by a partitioned table, you can use `REORGANIZE PARTITION`. This statement can be used in several ways:

- To merge a set of partitions into a single partition. This can be done by naming several partitions in the *partition_names* list and supplying a single definition for *partition_definition*.

- To split an existing partition into several partitions. You can accomplish this by naming a single partition for *partition_names* and providing multiple *partition_definitions*.
- To change the ranges for a subset of partitions defined using **VALUES LESS THAN** or the value lists for a subset of partitions defined using **VALUES IN**.

Note

For partitions that have not been explicitly named, MySQL automatically provides the default names **p0**, **p1**, **p2**, and so on. As of MySQL 5.1.7, the same is true with regard to subpartitions.

For more detailed information about and examples of **ALTER TABLE ... REORGANIZE PARTITION** statements, see [Section 17.3, “Partition Management”](#).

- Several additional clauses provide partition maintenance and repair functionality analogous to that implemented for non-partitioned tables by statements such as **CHECK TABLE** and **REPAIR TABLE** (which are *not* supported for partitioned tables). These include **ANALYZE PARTITION**, **CHECK PARTITION**, **OPTIMIZE PARTITION**, **REBUILD PARTITION**, and **REPAIR PARTITION**. Each of these options takes a *partition_names* clause consisting of one or more names of partitions, separated by commas. The partitions must already exist in the table to be altered. For more information, and for examples of these, see [Section 17.3.3, “Maintenance of Partitions”](#).
- **REMOVE PARTITIONING** was introduced in MySQL 5.1.8 for the purpose of removing a table's partitioning without otherwise affecting the table or its data. (Previously, this was done using the **ENGINE** option.) This option can be combined with other **ALTER TABLE** options such as those used to add, drop, or rename drop columns or indexes.

In MySQL 5.1.7 and earlier, using the **ENGINE** option with **ALTER TABLE** caused any partitioning that a table might have had to be removed. Beginning with MySQL 5.1.8, this option merely changes the storage engine used by the table and no longer affects partitioning in any way.

With the `mysql_info()` C API function, you can find out how many rows were copied, and (when **IGNORE** is used) how many rows were deleted due to duplication of unique key values. See [Section 25.2.3.35, “mysql_info\(\)”](#).

Here are some examples that show uses of **ALTER TABLE**. Begin with a table **t1** that is created as shown here:

```
CREATE TABLE t1 (a INTEGER,b CHAR(10));
```

To rename the table from **t1** to **t2**:

```
ALTER TABLE t1 RENAME t2;
```

To change column **a** from **INTEGER** to **TINYINT NOT NULL** (leaving the name the same), and to change column **b** from **CHAR(10)** to **CHAR(20)** as well as renaming it from **b** to **c**:

```
ALTER TABLE t2 MODIFY a TINYINT NOT NULL, CHANGE b c CHAR(20);
```

To add a new **TIMESTAMP** column named **d**:

```
ALTER TABLE t2 ADD d TIMESTAMP;
```

To add indexes on column **d** and on column **a**:

```
ALTER TABLE t2 ADD INDEX (d), ADD INDEX (a);
```

To remove column **c**:

```
ALTER TABLE t2 DROP COLUMN c;
```

To add a new **AUTO_INCREMENT** integer column named **c**:

```
ALTER TABLE t2 ADD c INT UNSIGNED NOT NULL AUTO_INCREMENT,  
ADD PRIMARY KEY (c);
```

Note that we indexed `c` (as a [PRIMARY KEY](#)), because [AUTO_INCREMENT](#) columns must be indexed, and also that we declare `c` as [NOT NULL](#), because primary key columns cannot be [NULL](#).

When you add an [AUTO_INCREMENT](#) column, column values are filled in with sequence numbers for you automatically. For [MyISAM](#) tables, you can set the first sequence number by executing [SET INSERT_ID=value](#) before [ALTER TABLE](#) or by using the [AUTO_INCREMENT=value](#) table option. See [Section 12.5.3, “SET Syntax”](#).

With [MyISAM](#) tables, if you do not change the [AUTO_INCREMENT](#) column, the sequence number is not affected. If you drop an [AUTO_INCREMENT](#) column and then add another [AUTO_INCREMENT](#) column, the numbers are resequenced beginning with 1.

When replication is used, adding an [AUTO_INCREMENT](#) column to a table might not produce the same ordering of the rows on the slave and the master. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the master and slave, the rows must be ordered before assigning an [AUTO_INCREMENT](#) number. Assuming that you want to add an [AUTO_INCREMENT](#) column to the table `t1`, the following statements produce a new table `t2` identical to `t1` but with an [AUTO_INCREMENT](#) column:

```
CREATE TABLE t2 (id INT AUTO_INCREMENT PRIMARY KEY)
SELECT * FROM t1 ORDER BY col1, col2;
```

This assumes that the table `t1` has columns `col1` and `col2`.

This set of statements will also produce a new table `t2` identical to `t1`, with the addition of an [AUTO_INCREMENT](#) column:

```
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

Important

To guarantee the same ordering on both master and slave, *all* columns of `t1` must be referenced in the [ORDER BY](#) clause.

Regardless of the method used to create and populate the copy having the [AUTO_INCREMENT](#) column, the final step is to drop the original table and then rename the copy:

```
DROP t1;
ALTER TABLE t2 RENAME t1;
```

See also [Section B.1.7.1, “Problems with ALTER TABLE”](#).

12.1.5. ALTER TABLESPACE Syntax

```
ALTER TABLESPACE tablespace
{ADD|DROP} DATAFILE 'file'
[INITIAL_SIZE [=] size]
[WAIT]
ENGINE [=] engine
```

This statement can be used either to add a new data file, or to drop a data file from a tablespace.

The [ADD DATAFILE](#) variant allows you to specify an initial size using an [INITIAL_SIZE](#) clause, where *size* is measured in bytes; the default value is [128M](#) (128 megabytes). You may optionally follow this integer value with a one-letter abbreviation for an order of magnitude, similar to those used in [my.cnf](#). Generally, this is one of the letters [M](#) (for megabytes) or [G](#) (for gigabytes).

Once a data file has been created, its size cannot be changed; however, you can add more data files to the tablespace using additional [ALTER TABLESPACE ... ADD DATAFILE](#) statements.

Using [DROP DATAFILE](#) with [ALTER TABLESPACE](#) drops the data file '*file*' from the tablespace. This file must already have been added to the tablespace using [CREATE TABLESPACE](#) or [ALTER TABLESPACE](#); otherwise an error will result.

Both [ALTER TABLESPACE ... ADD DATAFILE](#) and [ALTER TABLESPACE ... DROP DATAFILE](#) require an [ENGINE](#) clause which specifies the storage engine used by the tablespace. In MySQL 5.1, the only accepted values for *engine* are [NDB](#) and [NDBCLUSTER](#).

[WAIT](#) is parsed but otherwise ignored, and so has no effect in MySQL 5.1. It is intended for future expansion.

When [ALTER TABLESPACE ... ADD DATAFILE](#) is used with [ENGINE = NDB](#), a data file is created on each Cluster data node.

You can verify that the data files were created and obtain information about them by querying the `INFORMATION_SCHEMA.FILES` table. For example, the following query shows all data files belonging to the tablespace named `newts`:

```
mysql> SELECT LOGFILE_GROUP_NAME, FILE_NAME, EXTRA
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE TABLESPACE_NAME = 'newts' AND FILE_TYPE = 'DATAFILE';
```

LOGFILE_GROUP_NAME	FILE_NAME	EXTRA
lg_3	newdata.dat	CLUSTER_NODE=3
lg_3	newdata.dat	CLUSTER_NODE=4
lg_3	newdata2.dat	CLUSTER_NODE=3
lg_3	newdata2.dat	CLUSTER_NODE=4

2 rows in set (0.03 sec)

See [Section 23.21](#), “The `INFORMATION_SCHEMA.FILES` Table”.

`ALTER TABLESPACE` was added in MySQL 5.1.6. In MySQL 5.1, it is useful only with Disk Data storage for MySQL Cluster. See [Section 16.11](#), “MySQL Cluster Disk Data Tables”.

12.1.6. CREATE DATABASE Syntax

```
CREATE {DATABASE | SCHEMA} [IF NOT EXISTS] db_name
[create_specification ...]
```

```
create_specification:
[DEFAULT] CHARACTER SET charset_name
| [DEFAULT] COLLATE collation_name
```

`CREATE DATABASE` creates a database with the given name. To use this statement, you need the `CREATE` privilege for the database. `CREATE SCHEMA` is a synonym for `CREATE DATABASE`.

An error occurs if the database exists and you did not specify `IF NOT EXISTS`.

`create_specification` options specify database characteristics. Database characteristics are stored in the `db.opt` file in the database directory. The `CHARACTER SET` clause specifies the default database character set. The `COLLATE` clause specifies the default database collation. [Chapter 9, Character Set Support](#), discusses character set and collation names.

A database in MySQL is implemented as a directory containing files that correspond to tables in the database. Because there are no tables in a database when it is initially created, the `CREATE DATABASE` statement creates only a directory under the MySQL data directory and the `db.opt` file. Rules for allowable database names are given in [Section 8.2](#), “Identifiers”. If a database name contains special characters, the name for the database directory contains encoded versions of those characters as described in [Section 8.2.3](#), “Mapping of Identifiers to Filenames”.

If you manually create a directory under the data directory (for example, with `mkdir`), the server considers it a database directory and it shows up in the output of `SHOW DATABASES`.

You can also use the `mysqladmin` program to create databases. See [Section 7.10](#), “`mysqladmin` — Client for Administering a MySQL Server”.

12.1.7. CREATE INDEX Syntax

```
CREATE [UNIQUE|FULLTEXT|SPATIAL] INDEX index_name
[index_type]
ON tbl_name (index_col_name,...)
[index_option ...]
```

```
index_col_name:
col_name [(length)] [ASC | DESC]
```

```
index_type:
USING {BTREE | HASH | RTREE}
```

```
index_option:
KEY_BLOCK_SIZE value
| index_type
| WITH PARSER parser_name
```

`CREATE INDEX` is mapped to an `ALTER TABLE` statement to create indexes. See [Section 12.1.4](#), “`ALTER TABLE` Syntax”. `CREATE INDEX` cannot be used to create a `PRIMARY KEY`; use `ALTER TABLE` instead. For more information about indexes, see [Section 6.4.5](#), “How MySQL Uses Indexes”.

Normally, you create all indexes on a table at the time the table itself is created with `CREATE TABLE`. See [Section 12.1.10, “CREATE TABLE Syntax”](#). `CREATE INDEX` enables you to add indexes to existing tables.

A column list of the form `(col1,col2,...)` creates a multiple-column index. Index values are formed by concatenating the values of the given columns.

Indexes can be created that use only the leading part of column values, using `col_name(length)` syntax to specify an index prefix length:

- Prefixes can be specified for `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY` columns.
- `BLOB` and `TEXT` columns also can be indexed, but a prefix length *must* be given.
- Prefix lengths are given in characters for non-binary string types and in bytes for binary string types. That is, index entries consist of the first *length* characters of each column value for `CHAR`, `VARCHAR`, and `TEXT` columns, and the first *length* bytes of each column value for `BINARY`, `VARBINARY`, and `BLOB` columns.
- For spatial columns, prefix values can be given as described later in this section.

The statement shown here creates an index using the first 10 characters of the `name` column:

```
CREATE INDEX part_of_name ON customer (name(10));
```

If names in the column usually differ in the first 10 characters, this index should not be much slower than an index created from the entire `name` column. Also, using column prefixes for indexes can make the index file much smaller, which could save a lot of disk space and might also speed up `INSERT` operations.

Prefix lengths are storage engine-dependent (for example, a prefix can be up to 1000 bytes long for `MyISAM` tables, 767 bytes for `InnoDB` tables). Note that prefix limits are measured in bytes, whereas the prefix length in `CREATE INDEX` statements is interpreted as number of characters for non-binary data types (`CHAR`, `VARCHAR`, `TEXT`). Take this into account when specifying a prefix length for a column that uses a multi-byte character set. For example, `utf8` columns require up to three index bytes per character.

A `UNIQUE` index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. For all engines, a `UNIQUE` index allows multiple `NULL` values for columns that can contain `NULL`. If you specify a prefix value for a column in a `UNIQUE` index, the column values must be unique within the prefix.

MySQL Enterprise

Lack of proper indexes can greatly reduce performance. Subscribe to the MySQL Enterprise Monitor for notification of inefficient use of indexes. For more information see <http://www.mysql.com/products/enterprise/advisors.html>.

`FULLTEXT` indexes are supported only for `MyISAM` tables and can include only `CHAR`, `VARCHAR`, and `TEXT` columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See [Section 11.8, “Full-Text Search Functions”](#), for details of operation.

The `MyISAM`, `InnoDB`, `NDB`, `BDB`, and `ARCHIVE` storage engines support spatial columns such as (`POINT` and `GEOMETRY`. ([Chapter 18, Spatial Extensions](#), describes the spatial data types.) However, support for spatial column indexing varies among engines. Spatial and non-spatial indexes are available according to the following rules.

Spatial indexes (created using `SPATIAL INDEX`):

- Available only for `MyISAM` tables. Specifying a `SPATIAL INDEX` for other storage engines results in an error.
- Indexed columns must be `NOT NULL`.
- In MySQL 5.1, column prefix lengths are prohibited. The full width of each column is indexed.

Non-spatial indexes (created with `INDEX`, `UNIQUE`, or `PRIMARY KEY`):

- Allowed for any storage engine that supports spatial columns except `ARCHIVE`.

- Columns can be **NULL** unless the index is a primary key.
- For each spatial column in a non-**SPATIAL** index except **POINT** columns, a column prefix length must be specified. (This is the same requirement as for indexed **BLOB** columns.) The prefix length is given in bytes.
- The index type for a non-**SPATIAL** index depends on the storage engine. Currently, B-tree is used.

In MySQL 5.1:

- You can add an index on a column that can have **NULL** values only if you are using the **MyISAM**, **InnoDB**, or **MEMORY** storage engine.
- You can add an index on a **BLOB** or **TEXT** column only if you are using the **MyISAM**, or **InnoDB** storage engine.

An *index_col_name* specification can end with **ASC** or **DESC**. These keywords are allowed for future extensions for specifying ascending or descending index value storage. Currently, they are parsed but ignored; index values are always stored in ascending order.

Following the index column list, index options can be given. An *index_option* value can be any of the following:

- KEY_BLOCK_SIZE** *value*

This option provides a hint to the storage engine about the size to use for index key blocks. The engine is allowed to change the value if necessary. A value of 0 indicates that the default value should be used. **KEY_BLOCK_SIZE** was added in MySQL 5.1.10.

- index_type*

Some storage engines allow you to specify an index type when creating an index. The allowable index type values supported by different storage engines are shown in the following table. Where multiple index types are listed, the first one is the default when no index type specifier is given.

Storage Engine	Allowable Index Types
MyISAM	BTREE , RTREE
InnoDB	BTREE
MEMORY/HEAP	HASH , BTREE
NDB	HASH

The **RTREE** index type is allowable only for **SPATIAL** indexes.

If you specify an index type that is not legal for a given storage engine, but there is another index type available that the engine can use without affecting query results, the engine uses the available type.

Examples:

```
CREATE TABLE lookup (id INT) ENGINE = MEMORY;
CREATE INDEX id_index USING BTREE ON lookup (id);
```

For indexes on **NDB** table columns, the **USING** clause can be specified only for a unique index or primary key. In such cases, the **USING HASH** clause prevents the creation of an implicit ordered index. Without **USING HASH**, a statement defining a unique index or primary key automatically results in the creation of a **HASH** index in addition to the ordered index, both of which index the same set of columns.

TYPE type_name is recognized as a synonym for **USING type_name**. However, **USING** is the preferred form.

Note: Before MySQL 5.1.10, this option can be given only before the **ON tbl_name** clause. Use of the option in this position is deprecated as of 5.1.10; support for it is to be dropped in a future MySQL release.

- WITH PARSER** *parser_name*

This option can be used only with **FULLTEXT** indexes. It associates a parser plugin with the index if full-text indexing and search-

ing operations need special handling. See [Section 28.2, “The MySQL Plugin Interface”](#), for details on creating plugins.

12.1.8. CREATE LOGFILE GROUP Syntax

```
CREATE LOGFILE GROUP logfile_group
  ADD UNDOFILE 'undo_file'
  [INITIAL_SIZE [=] initial_size]
  [UNDO_BUFFER_SIZE [=] undo_buffer_size]
  [REDO_BUFFER_SIZE [=] redo_buffer_size]
  [NODEGROUP [=] nodegroup_id]
  [WAIT]
  [COMMENT [=] comment_text]
  [ENGINE [=] engine_name]
```

This statement creates a new log file group named *logfile_group* having a single **UNDO** file named '*undo_file*'. A **CREATE LOGFILE GROUP** statement has one and only one **ADD UNDOFILE** clause.

Beginning with MySQL 5.1.8, you can have only one log file group per Cluster at any given time. (See [Bug#16386](#))

The optional **INITIAL_SIZE** parameter sets the **UNDO** file's initial size; if not specified, it defaults to **128M** (128 megabytes). The optional **UNDO_BUFFER_SIZE** parameter sets the size used by the **UNDO** buffer for the log file group; The default value for **UNDO_BUFFER_SIZE** is **8M** (eight megabytes); this value cannot exceed the amount of system memory available. Both of these parameters are specified in bytes. You may optionally follow either or both of these with a one-letter abbreviation for an order of magnitude, similar to those used in *my.cnf*. Generally, this is one of the letters **M** (for megabytes) or **G** (for gigabytes).

The **ENGINE** parameter determines the storage engine to be used by this log file group, with *engine* being the name of the storage engine. In MySQL 5.1, *engine* must be one of the values **NDB** or **NDBCLUSTER**.

REDO_BUFFER_SIZE, **NODEGROUP**, **WAIT**, and **COMMENT** are parsed but ignored, and so have no effect in MySQL 5.1. These options are intended for future expansion.

When used with **ENGINE [=] NDB**, a log file group and associated **UNDO** log file are created on each Cluster data node. You can verify that the **UNDO** files were created and obtain information about them by querying the **INFORMATION_SCHEMA.FILES** table. For example:

```
mysql> SELECT LOGFILE_GROUP_NAME, LOGFILE_GROUP_NUMBER, EXTRA
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE FILE_NAME = 'undo_10.dat';
+-----+-----+-----+
| LOGFILE_GROUP_NAME | LOGFILE_GROUP_NUMBER | EXTRA          |
+-----+-----+-----+
| lg_3               | 11                   | CLUSTER_NODE=3 |
| lg_3               | 11                   | CLUSTER_NODE=4 |
+-----+-----+-----+
2 rows in set (0.06 sec)
```

(See [Section 23.21, “The INFORMATION_SCHEMA FILES Table”](#).)

CREATE LOGFILE GROUP was added in MySQL 5.1.6. In MySQL 5.1, it is useful only with Disk Data storage for MySQL Cluster. See [Section 16.11, “MySQL Cluster Disk Data Tables”](#).

12.1.9. CREATE SERVER Syntax

```
CREATE SERVER server_name
  FOREIGN DATA WRAPPER wrapper_name
  OPTIONS (option ...)

option:
{
  HOST character-literal
  DATABASE character-literal
  USER character-literal
  PASSWORD character-literal
  SOCKET character-literal
  OWNER character-literal
  PORT numeric-literal }
```

This statement creates the definition of a server for use with the **FEDERATED** storage engine. The **CREATE SERVER** statement creates a new row within the **servers** table within the **mysql** database. This statement requires the **SUPER** privilege.

The *server_name* should be a unique reference to the server. Server definitions are global within the scope of the server, it is not

possible to qualify the server definition to a specific database. *server_name* has a maximum length of 63 characters (names longer than 63 characters are silently truncated), and is case insensitive. You may specify the name using single quotes.

The *wrapper_name* should be `mysql`, and may be quoted with single quotes. Other values for *wrapper_name* are not currently supported.

For each *option* you must specify either a character literal or numeric literal. Character literals are UTF8, support a maximum length of 64 characters and default to a blank (empty) string. String literals are silently truncated to 64 characters. Numeric literals must be a number between 0 and 9999, default value is 0.

The `CREATE SERVER` statement creates an entry in the `mysql.server` table that can later be used with the `CREATE TABLE` statement when creating a `FEDERATED` table. The options that you specify will be used to populate the columns in the `mysql.server` table. The table columns are `Server_name`, `Host`, `Db`, `Username`, `Password`, `Port` and `Socket`.

For example:

```
CREATE SERVER s
FOREIGN DATA WRAPPER mysql
OPTIONS (USER 'Remote', HOST '192.168.1.106', DATABASE 'test');
```

The data stored in the table can be used when creating a connection to a `FEDERATED` table:

```
CREATE TABLE t (s1 INT) ENGINE=FEDERATED CONNECTION='s';
```

For more information, see [Section 13.9, “The FEDERATED Storage Engine”](#).

`CREATE SERVER` does not cause an automatic commit.

12.1.10. CREATE TABLE Syntax

```
CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
(create_definition,...)
[table_option ...]
[partition_options]
```

Or:

```
CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
[(create_definition,...)]
[table_option ...]
[PARTITION BY partition_options]
select_statement
```

Or:

```
CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
{ LIKE old_tbl_name | (LIKE old_tbl_name) }

create_definition:
  column_definition
| [CONSTRAINT [symbol]] PRIMARY KEY [index_type] (index_col_name,...)
  [index_option ...]

```

CREATE TABLE creates a table with the given name. You must have the **CREATE** privilege for the table.

Rules for allowable table names are given in [Section 8.2, “Identifiers”](#). By default, the table is created in the default database. An error occurs if the table exists, if there is no default database, or if the database does not exist.

The table name can be specified as *db_name.tbl_name* to create the table in a specific database. This works regardless of whether there is a default database, assuming that the database exists. If you use quoted identifiers, quote the database and table names separately. For example, write ``mydb`.`mytbl``, not ``mydb.mytbl``.

You can use the **TEMPORARY** keyword when creating a table. A **TEMPORARY** table is visible only to the current connection, and is dropped automatically when the connection is closed. This means that two different connections can use the same temporary table name without conflicting with each other or with an existing non-**TEMPORARY** table of the same name. (The existing table is hidden until the temporary table is dropped.) To create temporary tables, you must have the **CREATE TEMPORARY TABLES** privilege.

Note

CREATE TABLE does not automatically commit the current active transaction if you use the **TEMPORARY** keyword.

The keywords **IF NOT EXISTS** prevent an error from occurring if the table exists. However, there is no verification that the existing table has a structure identical to that indicated by the **CREATE TABLE** statement.

Note

If you use **IF NOT EXISTS** in a **CREATE TABLE ... SELECT** statement, any rows selected by the **SELECT** part are inserted regardless of whether the table already exists.

MySQL represents each table by an `.frm` table format (definition) file in the database directory. The storage engine for the table might create other files as well. In the case of **MyISAM** tables, the storage engine creates data and index files. Thus, for each **MyISAM** table *tbl_name*, there are three disk files:

File	Purpose
<i>tbl_name.frm</i>	Table format (definition) file
<i>tbl_name.MYD</i>	Data file
<i>tbl_name.MYI</i>	Index file

[Chapter 13, Storage Engines](#), describes what files each storage engine creates to represent tables. If a table name contains special characters, the names for the table files contain encoded versions of those characters as described in [Section 8.2.3, “Mapping of Identifiers to Filenames”](#).

data_type represents the data type is a column definition. *spatial_type* represents a spatial data type. The data type syntax shown is representative only. For a full description of the syntax available for specifying column data types, as well as information about the properties of each type, see [Chapter 10, Data Types](#), and [Chapter 18, Spatial Extensions](#).

Some attributes do not apply to all data types. **AUTO_INCREMENT** applies only to integer types. **DEFAULT** does not apply to the **BLOB** or **TEXT** types.

- If neither **NULL** nor **NOT NULL** is specified, the column is treated as though **NULL** had been specified.
- An integer column can have the additional attribute **AUTO_INCREMENT**. When you insert a value of **NULL** (recommended) or **0** into an indexed **AUTO_INCREMENT** column, the column is set to the next sequence value. Typically this is *value*+1, where *value* is the largest value for the column currently in the table. **AUTO_INCREMENT** sequences begin with 1.

To retrieve an **AUTO_INCREMENT** value after inserting a row, use the **LAST_INSERT_ID()** SQL function or the **mysql_insert_id()** C API function. See [Section 11.11.3, “Information Functions”](#), and [Section 25.2.3.37, “mysql_insert_id\(\)”](#).

If the **NO_AUTO_VALUE_ON_ZERO** SQL mode is enabled, you can store **0** in **AUTO_INCREMENT** columns as **0** without generating a new sequence value. See [Section 5.2.6, “SQL Modes”](#).

Note

There can be only one **AUTO_INCREMENT** column per table, it must be indexed, and it cannot have a **DEFAULT** value. An **AUTO_INCREMENT** column works properly only if it contains only positive values. Inserting a negative number is regarded as inserting a very large positive number. This is done to avoid precision problems when numbers “wrap” over from positive to negative and also to ensure that you do not accidentally get an **AUTO_INCREMENT** column that contains **0**.

For **MyISAM** tables, you can specify an **AUTO_INCREMENT** secondary column in a multiple-column key. See [Section 3.6.9, “Using AUTO_INCREMENT”](#).

To make MySQL compatible with some ODBC applications, you can find the **AUTO_INCREMENT** value for the last inserted row with the following query:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

For information about **InnoDB** and **AUTO_INCREMENT**, see [Section 13.5.6.3, “How AUTO_INCREMENT Handling Works in InnoDB”](#).

- Character data types (**CHAR**, **VARCHAR**, **TEXT**) can include **CHARACTER SET** and **COLLATE** attributes to specify the character set and collation for the column. For details, see [Chapter 9, Character Set Support](#). **CHARSET** is a synonym for **CHARACTER SET**. Example:

```
CREATE TABLE t (c CHAR(20) CHARACTER SET utf8 COLLATE utf8_bin);
```

MySQL 5.1 interprets length specifications in character column definitions in characters. (Versions before MySQL 4.1 interpreted them in bytes.) Lengths for **BINARY** and **VARBINARY** are in bytes.

- The **DEFAULT** clause specifies a default value for a column. With one exception, the default value must be a constant; it cannot be a function or an expression. This means, for example, that you cannot set the default for a date column to be the value of a function such as **NOW()** or **CURRENT_DATE**. The exception is that you can specify **CURRENT_TIMESTAMP** as the default for a **TIMESTAMP** column. See [Section 10.3.1.1, “TIMESTAMP Properties”](#).

If a column definition includes no explicit **DEFAULT** value, MySQL determines the default value as described in [Section 10.1.4, “Data Type Default Values”](#).

BLOB and **TEXT** columns cannot be assigned a default value.

- A comment for a column can be specified with the **COMMENT** option, up to 255 characters long. The comment is displayed by the **SHOW CREATE TABLE** and **SHOW FULL COLUMNS** statements.

MySQL Cluster 5.1 Carrier Grade Edition

The following information applies to users of MySQL Cluster 5.1 Carrier Grade Edition only. For more information about MySQL Cluster 5.1 Carrier Grade Edition, see [Section 16.2, “MySQL Cluster 5.1 Carrier Grade Edition”](#).

Beginning with MySQL 5.1.19-ndb-6.2.5 and MySQL 5.1.20-ndb-6.3.2, it is also possible to specify a data storage format for indi-

vidual columns of **NDB** tables using **COLUMN_FORMAT**. Allowable column formats are **FIXED**, **DYNAMIC**, and **DEFAULT**. **FIXED** is used to specify fixed-width storage, **DYNAMIC** allows the column to be variable-width, and **DEFAULT** causes the column to use fixed-width or variable-width storage as determined by the column's data type (possibly overridden by a **ROW_FORMAT** specifier).

For **NDB** tables, the default value for **COLUMN_FORMAT** is **DEFAULT**.

COLUMN_FORMAT has no effect on columns of tables using storage engines other than **NDB**.

The following information applies to all MySQL Cluster users.

MySQL Cluster 5.1 Carrier Grade Edition

The following information applies to users of MySQL Cluster 5.1 Carrier Grade Edition only. For more information about MySQL Cluster 5.1 Carrier Grade Edition, see Section 16.2, “MySQL Cluster 5.1 Carrier Grade Edition”.

For **NDB** tables, beginning with MySQL 5.1.19-ndb-6.2.5 and MySQL 5.1.20-ndb-6.3.2, it is also possible to specify whether the column is stored on disk or in memory by using a **STORAGE** clause. **STORAGE DISK** causes the column to be stored on disk, and **STORAGE MEMORY** causes in-memory storage to be used.

For **NDB** tables, the default is **MEMORY**.

The **STORAGE** clause has no effect on tables using storage engines other than **NDB**.

The following information applies to all MySQL Cluster users.

- **KEY** is normally a synonym for **INDEX**. The key attribute **PRIMARY KEY** can also be specified as just **KEY** when given in a column definition. This was implemented for compatibility with other database systems.
 - A **UNIQUE** index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. For all engines, a **UNIQUE** index allows multiple **NULL** values for columns that can contain **NULL**.
 - A **PRIMARY KEY** is a unique index where all key columns must be defined as **NOT NULL**. If they are not explicitly declared as **NOT NULL**, MySQL declares them so implicitly (and silently). A table can have only one **PRIMARY KEY**. If you do not have a **PRIMARY KEY** and an application asks for the **PRIMARY KEY** in your tables, MySQL returns the first **UNIQUE** index that has no **NULL** columns as the **PRIMARY KEY**.
- In **InnoDB** tables, having a long **PRIMARY KEY** wastes a lot of space. (See Section 13.5.13, “InnoDB Table and Index Structures”.)
- In the created table, a **PRIMARY KEY** is placed first, followed by all **UNIQUE** indexes, and then the non-unique indexes. This helps the MySQL optimizer to prioritize which index to use and also more quickly to detect duplicated **UNIQUE** keys.
 - A **PRIMARY KEY** can be a multiple-column index. However, you cannot create a multiple-column index using the **PRIMARY KEY** key attribute in a column specification. Doing so only marks that single column as primary. You must use a separate **PRIMARY KEY(index_col_name, ...)** clause.
 - If a **PRIMARY KEY** or **UNIQUE** index consists of only one column that has an integer type, you can also refer to the column as **_rowid** in **SELECT** statements.
 - In MySQL, the name of a **PRIMARY KEY** is **PRIMARY**. For other indexes, if you do not assign a name, the index is assigned the same name as the first indexed column, with an optional suffix (**_2**, **_3**, ...) to make it unique. You can see index names for a table using **SHOW INDEX FROM tbl_name**. See Section 12.5.4.18, “SHOW INDEX Syntax”.
 - Some storage engines allow you to specify an index type when creating an index. The syntax for the *index_type* specifier is **USING type_name**.

Example:

```
CREATE TABLE lookup
(id INT, INDEX USING BTREE (id))
ENGINE = MEMORY;
```

Before MySQL 5.1.10, **USING** can be given only before the index column list. As of 5.1.10, the preferred position is after the column list. Use of the option before the column list will no longer be recognized as of MySQL 5.3.

index_option values specify additional options for an index. **USING** is one such option. For details about allowable *index_option* values, see [Section 12.1.7, “CREATE INDEX Syntax”](#).

For more information about indexes, see [Section 6.4.5, “How MySQL Uses Indexes”](#).

- In MySQL 5.1, only the **MyISAM**, **InnoDB**, and **MEMORY** storage engines support indexes on columns that can have **NULL** values. In other cases, you must declare indexed columns as **NOT NULL** or an error results.
- For **CHAR**, **VARCHAR**, **BINARY**, and **VARBINARY** columns, indexes can be created that use only the leading part of column values, using *col_name(length)* syntax to specify an index prefix length. **BLOB** and **TEXT** columns also can be indexed, but a prefix length *must* be given. Prefix lengths are given in characters for non-binary string types and in bytes for binary string types. That is, index entries consist of the first *length* characters of each column value for **CHAR**, **VARCHAR**, and **TEXT** columns, and the first *length* bytes of each column value for **BINARY**, **VARBINARY**, and **BLOB** columns. Indexing only a prefix of column values like this can make the index file much smaller. See [Section 6.4.3, “Column Indexes”](#).

Only the **MyISAM** and **InnoDB** storage engines support indexing on **BLOB** and **TEXT** columns. For example:

```
CREATE TABLE test (blob_col BLOB, INDEX(blob_col(10)));
```

Prefixes can be up to 1000 bytes long (767 bytes for **InnoDB** tables). Note that prefix limits are measured in bytes, whereas the prefix length in **CREATE TABLE** statements is interpreted as number of characters for non-binary data types (**CHAR**, **VARCHAR**, **TEXT**). Take this into account when specifying a prefix length for a column that uses a multi-byte character set.

- An *index_col_name* specification can end with **ASC** or **DESC**. These keywords are allowed for future extensions for specifying ascending or descending index value storage. Currently, they are parsed but ignored; index values are always stored in ascending order.
- When you use **ORDER BY** or **GROUP BY** on a **TEXT** or **BLOB** column in a **SELECT**, the server sorts values using only the initial number of bytes indicated by the *max_sort_length* system variable. See [Section 10.4.3, “The BLOB and TEXT Types”](#).
- You can create special **FULLTEXT** indexes, which are used for full-text searches. Only the **MyISAM** storage engine supports **FULLTEXT** indexes. They can be created only from **CHAR**, **VARCHAR**, and **TEXT** columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See [Section 11.8, “Full-Text Search Functions”](#), for details of operation. A **WITH PARSER** clause can be specified as an *index_option* value to associate a parser plugin with the index if full-text indexing and searching operations need special handling. This clause is legal only for **FULLTEXT** indexes. See [Section 28.2, “The MySQL Plugin Interface”](#), for details on creating plugins.
- You can create **SPATIAL** indexes on spatial data types. Spatial types are supported only for **MyISAM** tables and indexed columns must be declared as **NOT NULL**. See [Chapter 18, Spatial Extensions](#).
- **InnoDB** tables support checking of foreign key constraints. See [Section 13.5, “The InnoDB Storage Engine”](#). Note that the **FOREIGN KEY** syntax in **InnoDB** is more restrictive than the syntax presented for the **CREATE TABLE** statement at the beginning of this section: The columns of the referenced table must always be explicitly named. **InnoDB** supports both **ON DELETE** and **ON UPDATE** actions on foreign keys. For the precise syntax, see [Section 13.5.6.4, “FOREIGN KEY Constraints”](#).

For other storage engines, MySQL Server parses and ignores the **FOREIGN KEY** and **REFERENCES** syntax in **CREATE TABLE** statements. The **CHECK** clause is parsed but ignored by all storage engines. See [Section 1.9.5.4, “Foreign Keys”](#).

Important

The inline **REFERENCES** specifications where the references are defined as part of the column specification are silently ignored by **InnoDB**. **InnoDB** only accepts **REFERENCES** clauses when specified as part of a separate **FOREIGN KEY** specification.

- For **MyISAM** tables, each **NULL** column takes one bit extra, rounded up to the nearest byte. The maximum row length in bytes can be calculated as follows:

```
row length = 1
              + (sum of column lengths)
              + (number of NULL columns + delete_flag + 7)/8
              + (number of variable-length columns)
```

delete_flag is 1 for tables with static row format. Static tables use a bit in the row record for a flag that indicates whether the row has been deleted. *delete_flag* is 0 for dynamic tables because the flag is stored in the dynamic row header.

These calculations do not apply for **InnoDB** tables, for which storage size is no different for **NULL** columns than for **NOT NULL** columns.

The **TABLESPACE ... STORAGE DISK** table option is used only with **NDB Cluster** tables. It assigns the table to a Cluster Disk Data tablespace. The tablespace named *tablespace_name* must already have been created using **CREATE TABLESPACE**. This table option was introduced in MySQL 5.1.6. See [Section 16.11, “MySQL Cluster Disk Data Tables”](#).

The **ENGINE** table option specifies the storage engine for the table.

The **ENGINE** table option takes the storage engine names shown in the following table.

Storage Engine	Description
ARCHIVE	The archiving storage engine. See Section 13.10, “The ARCHIVE Storage Engine” .
CSV	Tables that store rows in comma-separated values format. See Section 13.11, “The CSV Storage Engine” .
EXAMPLE	An example engine. See Section 13.8, “The EXAMPLE Storage Engine” .
FEDERATED	Storage engine that accesses remote tables. See Section 13.9, “The FEDERATED Storage Engine” .
HEAP	This is a synonym for MEMORY .
ISAM (OBSOLETE)	Not available in MySQL 5.1. If you are upgrading to MySQL 5.1 from a previous version, you should convert any existing ISAM tables to MyISAM before performing the upgrade.
InnoDB	Transaction-safe tables with row locking and foreign keys. See Section 13.5, “The InnoDB Storage Engine” .
MEMORY	The data for this storage engine is stored only in memory. See Section 13.7, “The MEMORY (HEAP) Storage Engine” .
MERGE	A collection of MyISAM tables used as one table. Also known as MRG_MyISAM . See Section 13.6, “The MERGE Storage Engine” .
MyISAM	The binary portable storage engine that is the default storage engine used by MySQL. See Section 13.4, “The MyISAM Storage Engine” .
NDBCLUSTER	Clustered, fault-tolerant, memory-based tables. Also known as NDB . See Chapter 16, MySQL Cluster .

If a storage engine is specified that is not available, MySQL uses the default engine instead. Normally, this is **MyISAM**. For example, if a table definition includes the **ENGINE=INNODB** option but the MySQL server does not support **INNODB** tables, the table is created as a **MyISAM** table. This makes it possible to have a replication setup where you have transactional tables on the master but tables created on the slave are non-transactional (to get more speed). In MySQL 5.1, a warning occurs if the storage engine specification is not honored.

Engine substitution can be controlled by the setting of the **NO_ENGINE_SUBSTITUTION** SQL mode, as described in [Section 5.2.6, “SQL Modes”](#).

Note

The older **TYPE** option was synonymous with **ENGINE**. **TYPE** has been deprecated since MySQL 4.0 but is still supported for backwards compatibility in MySQL 5.1 (excepting MySQL 5.1.7). Since MySQL 5.1.8, it produces a warning. It is scheduled for removal in MySQL 5.2. *You should not use **TYPE** in any new applications, and you should immediately begin conversion of existing applications to use **ENGINE** instead.* (See [Section C.1.22, “Changes in release 5.1.8 \(Not released\)”](#).)

The other table options are used to optimize the behavior of the table. In most cases, you do not have to specify any of them. These options apply to all storage engines unless otherwise indicated. Options that do not apply to a given storage engine may be accepted and remembered as part of the table definition. Such options then apply if you later use **ALTER TABLE** to convert the table to use a different storage engine.

- AUTO_INCREMENT**

The initial **AUTO_INCREMENT** value for the table. In MySQL 5.1, this works for **MyISAM**, **MEMORY**, and **InnoDB** tables. It also

works for [ARCHIVE](#) tables as of MySQL 5.1.6. To set the first auto-increment value for engines that do not support the [AUTO_INCREMENT](#) table option, insert a “dummy” row with a value one less than the desired value after creating the table, and then delete the dummy row.

For engines that support the [AUTO_INCREMENT](#) table option in [CREATE TABLE](#) statements, you can also use [ALTER TABLE tbl_name AUTO_INCREMENT = N](#) to reset the [AUTO_INCREMENT](#) value. The value cannot be set lower than the maximum value currently in the column.

- [AVG_ROW_LENGTH](#)

An approximation of the average row length for your table. You need to set this only for large tables with variable-size rows.

When you create a [MyISAM](#) table, MySQL uses the product of the [MAX_ROWS](#) and [AVG_ROW_LENGTH](#) options to decide how big the resulting table is. If you don't specify either option, the maximum size for a table is 256TB of data by default. (If your operating system does not support files that large, table sizes are constrained by the file size limit.) If you want to keep down the pointer sizes to make the index smaller and faster and you don't really need big files, you can decrease the default pointer size by setting the [myisam_data_pointer_size](#) system variable. (See [Section 5.2.3, “System Variables”](#).) If you want all your tables to be able to grow above the default limit and are willing to have your tables slightly slower and larger than necessary, you can increase the default pointer size by setting this variable. Setting the value to 7 allows table sizes up to 65,536TB.

- [\[DEFAULT\] CHARACTER SET](#)

Specify a default character set for the table. [CHARSET](#) is a synonym for [CHARACTER SET](#).

- [CHECKSUM](#)

Set this to 1 if you want MySQL to maintain a live checksum for all rows (that is, a checksum that MySQL updates automatically as the table changes). This makes the table a little slower to update, but also makes it easier to find corrupted tables. The [CHECKSUM TABLE](#) statement reports the checksum. ([MyISAM](#) only.)

- [COLLATE](#)

Specify a default collation for the table.

- [COMMENT](#)

A comment for the table, up to 60 characters long.

- [CONNECTION](#)

The connection string for a [FEDERATED](#) table.

Note

Older versions of MySQL used a [COMMENT](#) option for the connection string.

- [DATA DIRECTORY, INDEX DIRECTORY](#)

By using [DATA DIRECTORY='directory'](#) or [INDEX DIRECTORY='directory'](#) you can specify where the [MyISAM](#) storage engine should put a table's data file and index file. The directory must be the full pathname to the directory, not a relative path.

These options work only when you are not using the [--skip-symbolic-links](#) option. Your operating system must also have a working, thread-safe [realpath\(\)](#) call. See [Section 6.6.1.2, “Using Symbolic Links for Tables on Unix”](#), for more complete information.

If a [MyISAM](#) table is created with no [DATA DIRECTORY](#) option, the [.MYD](#) file is created in the database directory. By default, if [MyISAM](#) finds an existing [.MYD](#) file in this case, it overwrites it. The same applies to [.MYI](#) files for tables created with no [INDEX DIRECTORY](#) option. As of MySQL 5.1.23, to suppress this behavior, start the server with the [--keep_files_on_create](#) option, in which case [MyISAM](#) will not overwrite existing files and returns an error instead.

If a [MyISAM](#) table is created with a [DATA DIRECTORY](#) or [INDEX DIRECTORY](#) option and an existing [.MYD](#) or [.MYI](#) file is found, [MyISAM](#) always returns an error. It will not overwrite a file in the specified directory.

- [DELAY_KEY_WRITE](#)

Set this to 1 if you want to delay key updates for the table until the table is closed. See the description of the [delay_key_write](#) system variable in [Section 5.2.3, “System Variables”](#). (MyISAM only.)

- **INSERT_METHOD**

If you want to insert data into a [MERGE](#) table, you must specify with [INSERT_METHOD](#) the table into which the row should be inserted. [INSERT_METHOD](#) is an option useful for [MERGE](#) tables only. Use a value of [FIRST](#) or [LAST](#) to have inserts go to the first or last table, or a value of [NO](#) to prevent inserts. See [Section 13.6, “The MERGE Storage Engine”](#).

- **KEY_BLOCK_SIZE**

This option provides a hint to the storage engine about the size to use for index key blocks. The engine is allowed to change the value if necessary. A value of 0 indicates that the default value should be used. Individual index definitions can specify a [KEY_BLOCK_SIZE](#) value of their own to override the table value. [KEY_BLOCK_SIZE](#) was added in MySQL 5.1.10.

- **MAX_ROWS**

The maximum number of rows you plan to store in the table. This is not a hard limit, but rather a hint to the storage engine that the table must be able to store at least this many rows.

- **MIN_ROWS**

The minimum number of rows you plan to store in the table.

- **PACK_KEYS**

[PACK_KEYS](#) takes effect only with [MyISAM](#) tables. Set this option to 1 if you want to have smaller indexes. This usually makes updates slower and reads faster. Setting the option to 0 disables all packing of keys. Setting it to [DEFAULT](#) tells the storage engine to pack only long [CHAR](#) or [VARCHAR](#) columns.

If you do not use [PACK_KEYS](#), the default is to pack strings, but not numbers. If you use [PACK_KEYS=1](#), numbers are packed as well.

When packing binary number keys, MySQL uses prefix compression:

- Every key needs one extra byte to indicate how many bytes of the previous key are the same for the next key.
- The pointer to the row is stored in high-byte-first order directly after the key, to improve compression.

This means that if you have many equal keys on two consecutive rows, all following “same” keys usually only take two bytes (including the pointer to the row). Compare this to the ordinary case where the following keys takes [storage_size_for_key + pointer_size](#) (where the pointer size is usually 4). Conversely, you get a significant benefit from prefix compression only if you have many numbers that are the same. If all keys are totally different, you use one byte more per key, if the key is not a key that can have [NULL](#) values. (In this case, the packed key length is stored in the same byte that is used to mark if a key is [NULL](#).)

- **PASSWORD**

This option is unused. If you have a need to scramble your [.frm](#) files and make them unusable to any other MySQL server, please contact our sales department.

- **RAID_TYPE**

[RAID](#) support has been removed as of MySQL 5.0. For information on [RAID](#), see <http://dev.mysql.com/doc/refman/4.1/en/create-table.html>.

- **ROW_FORMAT**

Defines how the rows should be stored. For [MyISAM](#) tables, the option value can be [FIXED](#) or [DYNAMIC](#) for static or variable-length row format. [myisampack](#) sets the type to [COMPRESSED](#). See [Section 13.4.3, “MyISAM Table Storage Formats”](#).

For [InnoDB](#) tables, rows are stored in compact format ([ROW_FORMAT=COMPACT](#)) by default. The non-compact format used in older versions of MySQL can still be requested by specifying [ROW_FORMAT=REDUNDANT](#).

■ **Note**

During **CREATE TABLE**, if you specify a row format that the engine does support, the table will be created using the storage engines default row format. The information reported in this column in response to **SHOW TABLE STATUS** is the actual row format used. This may differ from the value in the **Create_options** column because the original **CREATE TABLE** definition is retained during creation.

- **UNION**

UNION is used when you want to access a collection of identical **MyISAM** tables as one. This works only with **MERGE** tables. See [Section 13.6, “The MERGE Storage Engine”](#).

You must have **SELECT**, **UPDATE**, and **DELETE** privileges for the tables you map to a **MERGE** table.

Note

Formerly, all tables used had to be in the same database as the **MERGE** table itself. This restriction no longer applies.)

partition_options can be used to control partitioning of the table created with **CREATE TABLE**.

Important

Not all options shown in the syntax for *partition_options* at the beginning of this section are available for all partitioning types. Please see the listings for the following individual types for information specific to each type, and see [Chapter 17, Partitioning](#), for more complete information about the workings of and uses for partitioning in MySQL, as well as additional examples of table creation and other statements relating to MySQL partitioning.

If used, *partition_options* is preceded by a **PARTITION BY** clause. This clause contains the function that is used to determine the partition; the function returns an integer value ranging from 1 to *num*, where *num* is the number of partitions. (The maximum number of user-defined partitions which a table may contain is 1024; the number of subpartitions — discussed later in this section — is included in this maximum.) The choices that are available for this function in MySQL 5.1 are shown in the following list:

- **HASH(*expr*)**: Hashes one or more columns to create a key for placing and locating rows. *expr* is an expression using one or more table columns. This can be any legal MySQL expression (including MySQL functions) that yields a single integer value. For example, these are all valid **CREATE TABLE** statements using **PARTITION BY HASH**:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5))
PARTITION BY HASH(col1);

CREATE TABLE t1 (col1 INT, col2 CHAR(5))
PARTITION BY HASH( ORD(col2) );

CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATETIME)
PARTITION BY HASH ( YEAR(col3) );
```

You may not use either **VALUES LESS THAN** or **VALUES IN** clauses with **PARTITION BY HASH**.

PARTITION BY HASH uses the remainder of *expr* divided by the number of partitions (that is, the modulus). For examples and additional information, see [Section 17.2.3, “HASH Partitioning”](#).

The **LINEAR** keyword entails a somewhat different algorithm. In this case, the number of the partition in which a row is stored is calculated as the result of one or more logical **AND** operations. For discussion and examples of linear hashing, see [Section 17.2.3.1, “LINEAR HASH Partitioning”](#).

- **KEY(*column_list*)**: This is similar to **HASH**, except that MySQL supplies the hashing function so as to guarantee an even data distribution. The *column_list* argument is simply a list of table columns. This example shows a simple table partitioned by key, with 4 partitions:

```
CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY KEY(col3)
PARTITIONS 4;
```

For tables that are partitioned by key, you can employ linear partitioning by using the **LINEAR** keyword. This has the same effect as with tables that are partitioned by **HASH**. That is, the partition number is found using the **&** operator rather than the modulus (see [Section 17.2.3.1, “LINEAR HASH Partitioning”](#), and [Section 17.2.4, “KEY Partitioning”](#), for details). This example uses linear partitioning by key to distribute data between 5 partitions:

```
CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY LINEAR KEY(col3)
PARTITIONS 5;
```

You may not use either **VALUES LESS THAN** or **VALUES IN** clauses with **PARTITION BY KEY**.

- **RANGE**: In this case, *expr* shows a range of values using a set of **VALUES LESS THAN** operators. When using range partitioning, you must define at least one partition using **VALUES LESS THAN**. You cannot use **VALUES IN** with range partitioning.

VALUES LESS THAN can be used with either a literal value or an expression that evaluates to a single value.

Suppose that you have a table that you wish to partition on a column containing year values, according to the following scheme:

Partition Number:	Years Range:
0	1990 and earlier
1	1991 – 1994
2	1995 – 1998
3	1999 – 2002
4	2003 – 2005
5	2006 and later

A table implementing such a partitioning scheme can be realized by the **CREATE TABLE** statement shown here:

```
CREATE TABLE t1 (
  year_col INT,
  some_data INT
)
PARTITION BY RANGE (year_col) (
  PARTITION p0 VALUES LESS THAN (1991),
  PARTITION p1 VALUES LESS THAN (1995),
  PARTITION p2 VALUES LESS THAN (1999),
  PARTITION p3 VALUES LESS THAN (2002),
  PARTITION p4 VALUES LESS THAN (2006),
  PARTITION p5 VALUES LESS THAN MAXVALUE
);
```

PARTITION ... VALUES LESS THAN ... statements work in a consecutive fashion. **VALUES LESS THAN MAXVALUE** works to specify “leftover” values that are greater than the maximum value otherwise specified.

Note that **VALUES LESS THAN** clauses work sequentially in a manner similar to that of the **case** portions of a **switch ... case** block (as found in many programming languages such as C, Java, and PHP). That is, the clauses must be arranged in such a way that the upper limit specified in each successive **VALUES LESS THAN** is greater than that of the previous one, with the one referencing **MAXVALUE** coming last of all in the list.

- **LIST(*expr*)**: This is useful when assigning partitions based on a table column with a restricted set of possible values, such as a state or country code. In such a case, all rows pertaining to a certain state or country can be assigned to a single partition, or a partition can be reserved for a certain set of states or countries. It is similar to **RANGE**, except that only **VALUES IN** may be used to specify allowable values for each partition.

VALUES IN is used with a list of values to be matched. For instance, you could create a partitioning scheme such as the following:

```
CREATE TABLE client_firms (
  id INT,
  name VARCHAR(35)
)
PARTITION BY LIST (id) (
  PARTITION r0 VALUES IN (1, 5, 9, 13, 17, 21),
  PARTITION r1 VALUES IN (2, 6, 10, 14, 18, 22),
  PARTITION r2 VALUES IN (3, 7, 11, 15, 19, 23),
  PARTITION r3 VALUES IN (4, 8, 12, 16, 20, 24)
);
```

When using list partitioning, you must define at least one partition using **VALUES IN**. You cannot use **VALUES LESS THAN** with **PARTITION BY LIST**.

Note

Currently, the value list used with **VALUES IN** must consist of integer values only.

- The number of partitions may optionally be specified with a **PARTITIONS num** clause, where *num* is the number of partitions. If both this clause *and* any **PARTITION** clauses are used, *num* must be equal to the total number of any partitions that are declared using **PARTITION** clauses.

Note

Whether or not you use a **PARTITIONS** clause in creating a table that is partitioned by **RANGE** or **LIST**, you must still include at least one **PARTITION VALUES** clause in the table definition (see below).

- A partition may optionally be divided into a number of subpartitions. This can be indicated by using the optional **SUBPARTITION BY** clause. Subpartitioning may be done by **HASH** or **KEY**. Either of these may be **LINEAR**. These work in the same way as previously described for the equivalent partitioning types. (It is not possible to subpartition by **LIST** or **RANGE**.)

The number of subpartitions can be indicated using the **SUBPARTITIONS** keyword followed by an integer value.

- MySQL 5.1.12 introduces rigorous checking of the value used in a **PARTITIONS** or **SUBPARTITIONS** clause. Beginning with this version, this value must adhere to the following rules:
 - The value must be a positive, non-zero integer.
 - No leading zeroes are permitted.
 - The value must be an integer literal, and cannot not be an expression. For example, **PARTITIONS 0.2E+01** is not allowed, even though **0.2E+01** evaluates to **2**. (Bug#15890)

Each partition may be individually defined using a *partition_definition* clause. The individual parts making up this clause are as follows:

- PARTITION partition_name**: This specifies a logical name for the partition.
- A **VALUES** clause: For range partitioning, each partition must include a **VALUES LESS THAN** clause; for list partitioning, you must specify a **VALUES IN** clause for each partition. This is used to determine which rows are to be stored in this partition. See the discussions of partitioning types in [Chapter 17, Partitioning](#), for syntax examples.
- An optional **COMMENT** clause may be used to describe the partition. The comment must be set off in single quotes. Example:

```
COMMENT = 'Data for the years previous to 1999'
```

- DATA DIRECTORY** and **INDEX DIRECTORY** may be used to indicate the directory where, respectively, the data and indexes for this partition are to be stored. Both the *data_dir* and the *index_dir* must be absolute system pathnames. Example:

```
CREATE TABLE th (id INT, name VARCHAR(30), adate DATE)
PARTITION BY LIST(YEAR(adate))
(
  PARTITION p1999 VALUES IN (1995, 1999, 2003)
    DATA DIRECTORY = '/var/appdata/95/data'
    INDEX DIRECTORY = '/var/appdata/95/idx',
  PARTITION p2000 VALUES IN (1996, 2000, 2004)
    DATA DIRECTORY = '/var/appdata/96/data'
    INDEX DIRECTORY = '/var/appdata/96/idx',
  PARTITION p2001 VALUES IN (1997, 2001, 2005)
    DATA DIRECTORY = '/var/appdata/97/data'
    INDEX DIRECTORY = '/var/appdata/97/idx',
  PARTITION p2000 VALUES IN (1998, 2002, 2006)
    DATA DIRECTORY = '/var/appdata/98/data'
    INDEX DIRECTORY = '/var/appdata/98/idx'
);
```

DATA DIRECTORY and **INDEX DIRECTORY** behave in the same way as in the **CREATE TABLE** statement's *table_option* clause as used for **MyISAM** tables.

One data directory and one index directory may be specified per partition. If left unspecified, the data and indexes are stored by de-

fault in the MySQL data directory.

On Windows, paths used for `DATA DIRECTORY` and `INDEX DIRECTORY` must use the `/` (slash) character and not the `\` (backslash) character. See [Section 17.1, “Overview of Partitioning in MySQL”](#), for an example.

Note

Prior to MySQL 5.1.18, `DATA DIRECTORY` and `INDEX DIRECTORY` were allowed even if the `NO_DIR_IN_CREATE` server SQL mode was in effect at the time that a partitioned table was created. Beginning with MySQL 5.1.18, these options are ignored for creating partitioned tables if `NO_DIR_IN_CREATE` is in effect. ([Bug#24633](#))

- `MAX_ROWS` and `MIN_ROWS` may be used to specify, respectively, the maximum and minimum number of rows to be stored in the partition. The values for `max_number_of_rows` and `min_number_of_rows` must be positive integers. As with the table-level options with the same names, these act only as “suggestions” to the server and are not hard limits.
- The optional `TABLESPACE` clause may be used to designate a tablespace for the partition. Used for MySQL Cluster only.
- The partitioning handler accepts a `[STORAGE] ENGINE` option for both `PARTITION` and `SUBPARTITION`. Currently, the only way in which this can be used is to set all partitions or all subpartitions to the same storage engine, and an attempt to set different storage engines for partitions or subpartitions in the same table will give rise to the error `ERROR 1469 (HY000): THE MIX OF HANDLERS IN THE PARTITIONS IS NOT ALLOWED IN THIS VERSION OF MYSQL`. We expect to lift this restriction on partitioning in a future MySQL release.
- The `NODEGROUP` option can be used to make this partition act as part of the node group identified by `node_group_id`. This option is applicable only to MySQL Cluster.
- The partition definition may optionally contain one or more `subpartition_definition` clauses. Each of these consists at a minimum of the `SUBPARTITION name`, where `name` is an identifier for the subpartition. Except for the replacement of the `PARTITION` keyword with `SUBPARTITION`, the syntax for a subpartition definition is identical to that for a partition definition.

Subpartitioning must be done by `HASH` or `KEY`, and can be done only on `RANGE` or `LIST` partitions. See [Section 17.2.5, “Subpartitioning”](#).

Partitions can be modified, merged, added to tables, and dropped from tables. For basic information about the MySQL statements to accomplish these tasks, see [Section 12.1.4, “ALTER TABLE Syntax”](#). For more detailed descriptions and examples, see [Section 17.3, “Partition Management”](#).

Important

The original `CREATE TABLE` statement, including all specifications and table options are stored by MySQL when the table is created. The information is retained so that if you change storage engines, collations or other settings using an `ALTER TABLE` statement, the original table options specified are retained. This allows you to change between `InnoDB` and `MyISAM` table types even though the row formats supported by the two engines are different.

Because the text of the original statement is retained, but due to the way that certain values and options may be silently re-configured (such as the `ROW_FORMAT`), the active table definition (accessible through `DESCRIBE` or with `SHOW TABLE STATUS` and the table creation string (accessible through `SHOW CREATE TABLE`) will report different values.

You can create one table from another by adding a `SELECT` statement at the end of the `CREATE TABLE` statement:

```
CREATE TABLE new_tbl SELECT * FROM orig_tbl;
```

MySQL creates new columns for all elements in the `SELECT`. For example:

```
mysql> CREATE TABLE test (a INT NOT NULL AUTO_INCREMENT,
-> PRIMARY KEY (a), KEY(b))
-> ENGINE=MyISAM SELECT b,c FROM test2;
```

This creates a `MyISAM` table with three columns, `a`, `b`, and `c`. Notice that the columns from the `SELECT` statement are appended to the right side of the table, not overlapped onto it. Take the following example:

```
mysql> SELECT * FROM foo;
+---+
| n |
```

```

+---+
| 1 |
+---+

mysql> CREATE TABLE bar (m INT) SELECT n FROM foo;
Query OK, 1 row affected (0.02 sec)
Records: 1 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM bar;
+-----+-----+
| m      | n      |
+-----+-----+
| NULL   | 1      |
+-----+-----+
1 row in set (0.00 sec)

```

For each row in table `foo`, a row is inserted in `bar` with the values from `foo` and default values for the new columns.

In a table resulting from `CREATE TABLE ... SELECT`, columns named only in the `CREATE TABLE` part come first. Columns named in both parts or only in the `SELECT` part come after that. The data type of `SELECT` columns can be overridden by also specifying the column in the `CREATE TABLE` part.

If any errors occur while copying the data to the table, it is automatically dropped and not created.

`CREATE TABLE ... SELECT` does not automatically create any indexes for you. This is done intentionally to make the statement as flexible as possible. If you want to have indexes in the created table, you should specify these before the `SELECT` statement:

```
mysql> CREATE TABLE bar (UNIQUE (n)) SELECT n FROM foo;
```

Some conversion of data types might occur. For example, the `AUTO_INCREMENT` attribute is not preserved, and `VARCHAR` columns can become `CHAR` columns.

When creating a table with `CREATE ... SELECT`, make sure to alias any function calls or expressions in the query. If you do not, the `CREATE` statement might fail or result in undesirable column names.

```

CREATE TABLE artists_and_works
SELECT artist.name, COUNT(work.artist_id) AS number_of_works
FROM artist LEFT JOIN work ON artist.id = work.artist_id
GROUP BY artist.id;

```

You can also explicitly specify the data type for a generated column:

```
CREATE TABLE foo (a TINYINT NOT NULL) SELECT b+1 AS a FROM bar;
```

Use `LIKE` to create an empty table based on the definition of another table, including any column attributes and indexes defined in the original table:

```
CREATE TABLE new_tbl LIKE orig_tbl;
```

The copy is created using the same version of the table storage format as the original table. The `SELECT` privilege is required on the original table.

`CREATE TABLE ... LIKE` does not preserve any `DATA DIRECTORY` or `INDEX DIRECTORY` table options that were specified for the original table, or any foreign key definitions.

You can precede the `SELECT` by `IGNORE` or `REPLACE` to indicate how to handle rows that duplicate unique key values. With `IGNORE`, new rows that duplicate an existing row on a unique key value are discarded. With `REPLACE`, new rows replace rows that have the same unique key value. If neither `IGNORE` nor `REPLACE` is specified, duplicate unique key values result in an error.

To ensure that the binary log can be used to re-create the original tables, MySQL does not allow concurrent inserts during `CREATE TABLE ... SELECT`.

12.1.10.1. Silent Column Specification Changes

In some cases, MySQL silently changes column specifications from those given in a `CREATE TABLE` or `ALTER TABLE` statement. These might be changes to a data type, to attributes associated with a data type, or to an index specification.

- `TIMESTAMP` display sizes are discarded.

Also note that **TIMESTAMP** columns are **NOT NULL** by default.

- Columns that are part of a **PRIMARY KEY** are made **NOT NULL** even if not declared that way.
- Trailing spaces are automatically deleted from **ENUM** and **SET** member values when the table is created.
- MySQL maps certain data types used by other SQL database vendors to MySQL types. See [Section 10.7, “Using Data Types from Other Database Engines”](#).
- If you include a **USING** clause to specify an index type that is not legal for a given storage engine, but there is another index type available that the engine can use without affecting query results, the engine uses the available type.

To see whether MySQL used a data type other than the one you specified, issue a **DESCRIBE** or **SHOW CREATE TABLE** statement after creating or altering the table.

Certain other data type changes can occur if you compress a table using **myisampack**. See [Section 13.4.3.3, “Compressed Table Characteristics”](#).

12.1.11. CREATE TABLESPACE Syntax

```
CREATE TABLESPACE tablespace
  ADD DATAFILE 'file'
  USE LOGFILE GROUP logfile_group
  [EXTENT_SIZE [=] extent_size]
  [INITIAL_SIZE [=] initial_size]
  [AUTOEXTEND_SIZE [=] autoextend_size]
  [MAX_SIZE [=] max_size]
  [NODEGROUP [=] nodegroup_id]
  [WAIT]
  [COMMENT [=] comment_text]
  ENGINE [=] engine
```

This statement is used to create a tablespace, which can contain one or more data files, providing storage space for tables. One data file is created and added to the tablespace using this statement. Additional data files may be added to the tablespace by using the **ALTER TABLESPACE** statement (see [Section 12.1.5, “ALTER TABLESPACE Syntax”](#)).

A log file group of one or more **UNDO** log files must be assigned to the tablespace to be created with the **USE LOGFILE GROUP** clause. *logfile_group* must be an existing log file group created with **CREATE LOGFILE GROUP** (see [Section 12.1.8, “CREATE LOGFILE GROUP Syntax”](#)). Multiple tablespaces may use the same log file group for **UNDO** logging.

The **EXTENT_SIZE** sets the size, in bytes, of the extents used by any files belonging to the tablespace. The default value is 1M. The minimum size is 32K, and the theoretical maximum is 2G, although the practical maximum size depends on a number of factors.

An *extent* is a unit of disk space allocation. One extent is filled with as much data as that extent can contain before another extent is used. In theory, up to 65,535 (64K) extents may be used per data file; however, the recommended maximum is 32,768 (32K). The recommended maximum size for a single data file is 32G — that is, 32K extents × 1 MB per extent. Smaller extents have the advantage that they tend to provide lower latency; however, larger extents tend to allow for greater throughput. You must also take into consideration that larger extents may mean longer node restart times. In addition, once an extent is allocated to a given table, it cannot be used to store data from another; an extent cannot store table data from more than one table. This means, for example, that a tablespace having a single datafile whose **INITIAL_SIZE** is 256 MB and whose **EXTENT_SIZE** is 128M has just two extents, and so can be used to store data from at most two different disk data tables.

You can see how many extents remain free in a given data file by querying the **INFORMATION_SCHEMA.FILES** table, and so derive an estimate for how much space remains free in the file. For further discussion and examples, see [Section 23.21, “The INFORMATION_SCHEMA FILES Table”](#).

The **INITIAL_SIZE** parameter sets the data file's total size in bytes. Once the file has been created, its size cannot be changed; however, you can add more data files to the tablespace using **ALTER TABLESPACE ... ADD DATAFILE**. See [Section 12.1.5, “ALTER TABLESPACE Syntax”](#).

INITIAL_SIZE is optional; its default value is **128M**.

When setting **EXTENT_SIZE** or **INITIAL_SIZE** (either or both), you may optionally follow the number with a one-letter abbreviation for an order of magnitude, similar to those used in **my.cnf**. Generally, this is one of the letters **M** (for megabytes) or **G** (for gigabytes).

`AUTOEXTEND_SIZE`, `MAX_SIZE`, `NODEGROUP`, `WAIT`, and `COMMENT` are parsed but ignored, and so have no effect in MySQL 5.1. These options are intended for future expansion.

The `ENGINE` parameter determines the storage engine which uses this tablespace, with `engine` being the name of the storage engine. In MySQL 5.1, `engine` must be one of the values `NDB` or `NDBCLUSTER`.

When `CREATE TABLESPACE` is used with `ENGINE = NDB`, a tablespace and associated data file are created on each Cluster data node. You can verify that the data files were created and obtain information about them by querying the `INFORMATION_SCHEMA.FILES` table. For example:

```
mysql> SELECT LOGFILE_GROUP_NAME, FILE_NAME, EXTRA
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE TABLESPACE_NAME = 'newts' AND FILE_TYPE = 'DATAFILE';
+-----+-----+-----+
| LOGFILE_GROUP_NAME | FILE_NAME | EXTRA |
+-----+-----+-----+
| lg_3               | newdata.dat | CLUSTER_NODE=3 |
| lg_3               | newdata.dat | CLUSTER_NODE=4 |
+-----+-----+-----+
2 rows in set (0.01 sec)
```

(See [Section 23.21](#), “The `INFORMATION_SCHEMA.FILES` Table”.)

`CREATE TABLESPACE` was added in MySQL 5.1.6. In MySQL 5.1, it is useful only with Disk Data storage for MySQL Cluster. See [Section 16.11](#), “MySQL Cluster Disk Data Tables”.

12.1.12. DROP DATABASE Syntax

```
DROP {DATABASE | SCHEMA} [IF EXISTS] db_name
```

`DROP DATABASE` drops all tables in the database and deletes the database. Be very careful with this statement! To use `DROP DATABASE`, you need the `DROP` privilege on the database. `DROP SCHEMA` is a synonym for `DROP DATABASE`.

Important

When a database is dropped, user privileges on the database are *not* automatically dropped. See [Section 12.5.1.3](#), “`GRANT Syntax`”.

`IF EXISTS` is used to prevent an error from occurring if the database does not exist.

If you use `DROP DATABASE` on a symbolically linked database, both the link and the original database are deleted.

`DROP DATABASE` returns the number of tables that were removed. This corresponds to the number of `.frm` files removed.

The `DROP DATABASE` statement removes from the given database directory those files and directories that MySQL itself may create during normal operation:

- All files with these extensions:

<code>.BAK</code>	<code>.DAT</code>	<code>.HSH</code>	<code>.MRG</code>
<code>.MYD</code>	<code>.MYI</code>	<code>.TRG</code>	<code>.TRN</code>
<code>.db</code>	<code>.frm</code>	<code>.ibd</code>	<code>.ndb</code>
<code>.par</code>			

- The `db.opt` file, if it exists.

If other files or directories remain in the database directory after MySQL removes those just listed, the database directory cannot be removed. In this case, you must remove any remaining files or directories manually and issue the `DROP DATABASE` statement again.

You can also drop databases with `mysqladmin`. See [Section 7.10](#), “`mysqladmin` — Client for Administering a MySQL Server”.

12.1.13. DROP INDEX Syntax

```
DROP INDEX index_name ON tbl_name
```

DROP INDEX drops the index named *index_name* from the table *tbl_name*. This statement is mapped to an **ALTER TABLE** statement to drop the index. See [Section 12.1.4, “ALTER TABLE Syntax”](#).

12.1.14. DROP LOGFILE GROUP Syntax

```
DROP LOGFILE GROUP logfile_group
ENGINE [=] engine
```

This statement drops the log file group named *logfile_group*. The log file group must already exist or an error results. (For information on creating log file groups, see [Section 12.1.8, “CREATE LOGFILE GROUP Syntax”](#).)

Important

Before dropping a log file group, you must drop all tablespaces that use that log file group for **UNDO** logging.

The required **ENGINE** clause provides the name of the storage engine used by the log file group to be dropped. In MySQL 5.1, the only permitted values for *engine* are **NDB** and **NDBCLUSTER**.

DROP LOGFILE GROUP was added in MySQL 5.1.6. In MySQL 5.1, it is useful only with Disk Data storage for MySQL Cluster. See [Section 16.11, “MySQL Cluster Disk Data Tables”](#).

12.1.15. DROP SERVER Syntax

```
DROP SERVER [ IF EXISTS ] server_name
```

Drops the server definition for the server named *server_name*. The corresponding row within the `mysql.servers` table will be deleted. This statement requires the **SUPER** privilege.

Dropping a server for a table does not affect any **FEDERATED** tables that used this connection information when they were created. See [Section 12.1.9, “CREATE SERVER Syntax”](#).

DROP SERVER does not cause an automatic commit.

12.1.16. DROP TABLE Syntax

```
DROP [TEMPORARY] TABLE [IF EXISTS]
tbl_name [, tbl_name] ...
[RESTRICT | CASCADE]
```

DROP TABLE removes one or more tables. You must have the **DROP** privilege for each table. All table data and the table definition are *removed, so be careful* with this statement! If any of the tables named in the argument list do not exist, MySQL returns an error indicating by name which non-existing tables it was unable to drop, but it also drops all of the tables in the list that do exist.

Important

When a table is dropped, user privileges on the table are *not* automatically dropped. See [Section 12.5.1.3, “GRANT Syntax”](#).

Note that for a partitioned table, **DROP TABLE** permanently removes the table definition, all of its partitions, and all of the data which was stored in those partitions. It also removes the partitioning definition (`.par`) file associated with the dropped table.

Use **IF EXISTS** to prevent an error from occurring for tables that do not exist. A **NOTE** is generated for each non-existent table when using **IF EXISTS**. See [Section 12.5.4.32, “SHOW WARNINGS Syntax”](#).

RESTRICT and **CASCADE** are allowed to make porting easier. In MySQL 5.1, they do nothing.

Note

DROP TABLE automatically commits the current active transaction, unless you use the **TEMPORARY** keyword.

The **TEMPORARY** keyword has the following effects:

- The statement drops only **TEMPORARY** tables.
- The statement does not end an ongoing transaction.
- No access rights are checked. (A **TEMPORARY** table is visible only to the client that created it, so no check is necessary.)

Using **TEMPORARY** is a good way to ensure that you do not accidentally drop a non-**TEMPORARY** table.

12.1.17. DROP TABLESPACE Syntax

```
DROP TABLESPACE tablespace
ENGINE [=] engine
```

This statement drops a tablespace that was previously created using **CREATE TABLESPACE** (see [Section 12.1.11, “CREATE TABLESPACE Syntax”](#)).

Important

The tablespace to be dropped must not contain any data files; in other words, before you can drop a tablespace, you must first drop each of its data files using **ALTER TABLESPACE ... DROP DATAFILE** (see [Section 12.1.5, “ALTER TABLESPACE Syntax”](#)).

The **ENGINE** clause (required) specifies the storage engine used by the tablespace. In MySQL 5.1, the only accepted values for *engine* are **NDB** and **NDBCLUSTER**.

DROP TABLESPACE was added in MySQL 5.1.6. In MySQL 5.1, it is useful only with Disk Data storage for MySQL Cluster. See [Section 16.11, “MySQL Cluster Disk Data Tables”](#).

12.1.18. RENAME DATABASE Syntax

```
RENAME {DATABASE | SCHEMA} db_name TO new_db_name;
```

This statement renames a database. It requires the **ALTER** and **DROP** privileges for the database, and the **CREATE** privilege for the new database. **RENAME SCHEMA** is a synonym for **RENAME DATABASE**.

When the server receives this statement, it creates a new database. Then it moves tables and other database objects such as triggers to the new database. It also updates the **Db** column in the system tables for objects such as stored routines and events. Finally, the server drops the old database.

Note that currently there are these limitations:

- **RENAME DATABASE** does not change any account privileges listed in the system tables. They must be changed manually.
- **RENAME DATABASE** destroys any stored routines or events associated with the original database.

This statement was added in MySQL 5.1.7.

12.1.19. RENAME TABLE Syntax

```
RENAME TABLE tbl_name TO new_tbl_name
[, tbl_name2 TO new_tbl_name2] ...
```

This statement renames one or more tables.

The rename operation is done atomically, which means that no other thread can access any of the tables while the rename is running. For example, if you have an existing table **old_table**, you can create another table **new_table** that has the same structure but is empty, and then replace the existing table with the empty one as follows (assuming that **backup_table** does not already exist):

```
CREATE TABLE new_table (...);
RENAME TABLE old_table TO backup_table, new_table TO old_table;
```

If the statement renames more than one table, renaming operations are done from left to right. If you want to swap two table names, you can do so like this (assuming that `tmp_table` does not already exist):

```
RENAME TABLE old_table TO tmp_table,  
              new_table TO old_table,  
              tmp_table TO new_table;
```

As long as two databases are on the same filesystem, you can use `RENAME TABLE` to move a table from one database to another:

```
RENAME TABLE current_db.tbl_name TO other_db.tbl_name;
```

If there are any triggers associated with a table which is moved to a different database using `RENAME TABLE`, then the statement fails with the error `TRIGGER IN WRONG SCHEMA`.

`RENAME TABLE` also works for views, as long as you do not try to rename a view into a different database.

Any privileges granted specifically for the renamed table or view are not migrated to the new name. They must be changed manually.

When you execute `RENAME`, you cannot have any locked tables or active transactions. You must also have the `ALTER` and `DROP` privileges on the original table, and the `CREATE` and `INSERT` privileges on the new table.

If MySQL encounters any errors in a multiple-table rename, it does a reverse rename for all renamed tables to return everything to its original state.

12.2. Data Manipulation Statements

12.2.1. DELETE Syntax

Single-table syntax:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE] FROM tbl_name  
      [WHERE where_condition]  
      [ORDER BY ...]  
      [LIMIT row_count]
```

Multiple-table syntax:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]  
      tbl_name[.*] [, tbl_name[.*]] ...  
      FROM table_references  
      [WHERE where_condition]
```

Or:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]  
      FROM tbl_name[.*] [, tbl_name[.*]] ...  
      USING table_references  
      [WHERE where_condition]
```

For the single-table syntax, the `DELETE` statement deletes rows from `tbl_name` and returns the number of rows deleted. The `WHERE` clause, if given, specifies the conditions that identify which rows to delete. With no `WHERE` clause, all rows are deleted. If the `ORDER BY` clause is specified, the rows are deleted in the order that is specified. The `LIMIT` clause places a limit on the number of rows that can be deleted.

For the multiple-table syntax, `DELETE` deletes from each `tbl_name` the rows that satisfy the conditions. In this case, `ORDER BY` and `LIMIT` cannot be used.

`where_condition` is an expression that evaluates to true for each row to be deleted. It is specified as described in [Section 12.2.7, “SELECT Syntax”](#).

As stated, a `DELETE` statement with no `WHERE` clause deletes all rows. A faster way to do this, when you do not want to know the number of deleted rows, is to use `TRUNCATE TABLE`. See [Section 12.2.9, “TRUNCATE Syntax”](#).

If you delete the row containing the maximum value for an `AUTO_INCREMENT` column, the value is not reused for a `MyISAM` or `InnoDB` table. If you delete all rows in the table with `DELETE FROM tbl_name` (without a `WHERE` clause) in `AUTOCOMMIT` mode,

the sequence starts over for all storage engines except **InnoDB** and **MyISAM**. There are some exceptions to this behavior for **InnoDB** tables, as discussed in [Section 13.5.6.3, “How AUTO_INCREMENT Handling Works in InnoDB”](#).

For **MyISAM** tables, you can specify an **AUTO_INCREMENT** secondary column in a multiple-column key. In this case, reuse of values deleted from the top of the sequence occurs even for **MyISAM** tables. See [Section 3.6.9, “Using AUTO_INCREMENT”](#).

The **DELETE** statement supports the following modifiers:

- If you specify **LOW_PRIORITY**, the server delays execution of the **DELETE** until no other clients are reading from the table. This affects only storage engines that use only table-level locking (**MyISAM**, **MEMORY**, **MERGE**).
- For **MyISAM** tables, if you use the **QUICK** keyword, the storage engine does not merge index leaves during delete, which may speed up some kinds of delete operations.
- The **IGNORE** keyword causes MySQL to ignore all errors during the process of deleting rows. (Errors encountered during the parsing stage are processed in the usual manner.) Errors that are ignored due to the use of **IGNORE** are returned as warnings.

The speed of delete operations may also be affected by factors discussed in [Section 6.2.19, “Speed of DELETE Statements”](#).

In **MyISAM** tables, deleted rows are maintained in a linked list and subsequent **INSERT** operations reuse old row positions. To reclaim unused space and reduce file sizes, use the **OPTIMIZE TABLE** statement or the **myisamchk** utility to reorganize tables. **OPTIMIZE TABLE** is easier, but **myisamchk** is faster. See [Section 12.5.2.5, “OPTIMIZE TABLE Syntax”](#), and [Section 7.5, “myisamchk — MyISAM Table-Maintenance Utility”](#).

The **QUICK** modifier affects whether index leaves are merged for delete operations. **DELETE QUICK** is most useful for applications where index values for deleted rows are replaced by similar index values from rows inserted later. In this case, the holes left by deleted values are reused.

DELETE QUICK is not useful when deleted values lead to underfilled index blocks spanning a range of index values for which new inserts occur again. In this case, use of **QUICK** can lead to wasted space in the index that remains unreclaimed. Here is an example of such a scenario:

1. Create a table that contains an indexed **AUTO_INCREMENT** column.
2. Insert many rows into the table. Each insert results in an index value that is added to the high end of the index.
3. Delete a block of rows at the low end of the column range using **DELETE QUICK**.

In this scenario, the index blocks associated with the deleted index values become underfilled but are not merged with other index blocks due to the use of **QUICK**. They remain underfilled when new inserts occur, because new rows do not have index values in the deleted range. Furthermore, they remain underfilled even if you later use **DELETE** without **QUICK**, unless some of the deleted index values happen to lie in index blocks within or adjacent to the underfilled blocks. To reclaim unused index space under these circumstances, use **OPTIMIZE TABLE**.

If you are going to delete many rows from a table, it might be faster to use **DELETE QUICK** followed by **OPTIMIZE TABLE**. This rebuilds the index rather than performing many index block merge operations.

The MySQL-specific **LIMIT row_count** option to **DELETE** tells the server the maximum number of rows to be deleted before control is returned to the client. This can be used to ensure that a given **DELETE** statement does not take too much time. You can simply repeat the **DELETE** statement until the number of affected rows is less than the **LIMIT** value.

If the **DELETE** statement includes an **ORDER BY** clause, the rows are deleted in the order specified by the clause. This is really useful only in conjunction with **LIMIT**. For example, the following statement finds rows matching the **WHERE** clause, sorts them by **timestamp_column**, and deletes the first (oldest) one:

```
DELETE FROM somelog WHERE user = 'jcole'  
ORDER BY timestamp_column LIMIT 1;
```

You can specify multiple tables in a **DELETE** statement to delete rows from one or more tables depending on the particular condition in the **WHERE** clause. However, you cannot use **ORDER BY** or **LIMIT** in a multiple-table **DELETE**. The *table_references* clause lists the tables involved in the join. Its syntax is described in [Section 12.2.7.1, “JOIN Syntax”](#).

For the first multiple-table syntax, only matching rows from the tables listed before the **FROM** clause are deleted. For the second mul-

tuple-table syntax, only matching rows from the tables listed in the **FROM** clause (before the **USING** clause) are deleted. The effect is that you can delete rows from many tables at the same time and have additional tables that are used only for searching:

```
DELETE t1, t2 FROM t1, t2, t3 WHERE t1.id=t2.id AND t2.id=t3.id;
```

Or:

```
DELETE FROM t1, t2 USING t1, t2, t3 WHERE t1.id=t2.id AND t2.id=t3.id;
```

These statements use all three tables when searching for rows to delete, but delete matching rows only from tables **t1** and **t2**.

The preceding examples show inner joins that use the comma operator, but multiple-table **DELETE** statements can use any type of join allowed in **SELECT** statements, such as **LEFT JOIN**.

The syntax allows **. *** after the table names for compatibility with **Access**.

If you use a multiple-table **DELETE** statement involving **InnoDB** tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, you should delete from a single table and rely on the **ON DELETE** capabilities that **InnoDB** provides to cause the other tables to be modified accordingly.

Note

If you provide an alias for a table, you must use the alias when referring to the table:

```
DELETE t1 FROM test AS t1, test2 WHERE ...
```

Cross-database deletes are supported for multiple-table deletes, but in this case, you must refer to the tables without using aliases. For example:

```
DELETE test1.tmp1, test2.tmp2 FROM test1.tmp1, test2.tmp2 WHERE ...
```

Currently, you cannot delete from a table and select from the same table in a subquery.

12.2.2. DO Syntax

```
DO expr [, expr] ...
```

DO executes the expressions but does not return any results. In most respects, **DO** is shorthand for **SELECT *expr*, ...**, but has the advantage that it is slightly faster when you do not care about the result.

DO is useful primarily with functions that have side effects, such as **RELEASE_LOCK()**.

12.2.3. HANDLER Syntax

```
HANDLER tbl_name OPEN [ [AS] alias ]
HANDLER tbl_name READ index_name { = | >= | <= | < } (value1,value2,...)
[ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name READ index_name { FIRST | NEXT | PREV | LAST }
[ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name READ { FIRST | NEXT }
[ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name CLOSE
```

The **HANDLER** statement provides direct access to table storage engine interfaces. It is available for **MyISAM** and **InnoDB** tables.

The **HANDLER ... OPEN** statement opens a table, making it accessible via subsequent **HANDLER ... READ** statements. This table object is not shared by other threads and is not closed until the thread calls **HANDLER ... CLOSE** or the thread terminates. If you open the table using an alias, further references to the open table with other **HANDLER** statements must use the alias rather than the table name.

The first **HANDLER ... READ** syntax fetches a row where the index specified satisfies the given values and the **WHERE** condition is met. If you have a multiple-column index, specify the index column values as a comma-separated list. Either specify values for all the columns in the index, or specify values for a leftmost prefix of the index columns. Suppose that an index **my_idx** includes three columns named **col_a**, **col_b**, and **col_c**, in that order. The **HANDLER** statement can specify values for all three columns in the in-

dex, or for the columns in a leftmost prefix. For example:

```
HANDLER ... READ my_idx = (col_a_val,col_b_val,col_c_val) ...
HANDLER ... READ my_idx = (col_a_val,col_b_val) ...
HANDLER ... READ my_idx = (col_a_val) ...
```

To employ the **HANDLER** interface to refer to a table's **PRIMARY KEY**, use the quoted identifier ``PRIMARY``:

```
HANDLER tbl_name READ `PRIMARY` ...
```

The second **HANDLER ... READ** syntax fetches a row from the table in index order that matches the **WHERE** condition.

The third **HANDLER ... READ** syntax fetches a row from the table in natural row order that matches the **WHERE** condition. It is faster than **HANDLER tbl_name READ index_name** when a full table scan is desired. Natural row order is the order in which rows are stored in a **MyISAM** table data file. This statement works for **InnoDB** tables as well, but there is no such concept because there is no separate data file.

Without a **LIMIT** clause, all forms of **HANDLER ... READ** fetch a single row if one is available. To return a specific number of rows, include a **LIMIT** clause. It has the same syntax as for the **SELECT** statement. See [Section 12.2.7, “SELECT Syntax”](#).

HANDLER ... CLOSE closes a table that was opened with **HANDLER ... OPEN**.

HANDLER is a somewhat low-level statement. For example, it does not provide consistency. That is, **HANDLER ... OPEN** does *not* take a snapshot of the table, and does *not* lock the table. This means that after a **HANDLER ... OPEN** statement is issued, table data can be modified (by the current thread or other threads) and these modifications might be only partially visible to **HANDLER ... NEXT** or **HANDLER ... PREV** scans.

There are several reasons to use the **HANDLER** interface instead of normal **SELECT** statements:

- **HANDLER** is faster than **SELECT**:
 - A designated storage engine handler object is allocated for the **HANDLER ... OPEN**. The object is reused for subsequent **HANDLER** statements for that table; it need not be reinitialized for each one.
 - There is less parsing involved.
 - There is no optimizer or query-checking overhead.
 - The table does not have to be locked between two handler requests.
 - The handler interface does not have to provide a consistent look of the data (for example, dirty reads are allowed), so the storage engine can use optimizations that **SELECT** does not normally allow.
- For applications that use a low-level **ISAM**-like interface, **HANDLER** makes it much easier to port them to MySQL.
- **HANDLER** enables you to traverse a database in a manner that is difficult (or even impossible) to accomplish with **SELECT**. The **HANDLER** interface is a more natural way to look at data when working with applications that provide an interactive user interface to the database.

12.2.4. INSERT Syntax

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name [(col_name,...)]
VALUES ({expr | DEFAULT},...), (...),...
[ ON DUPLICATE KEY UPDATE col_name=expr, ... ]
```

Or:

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name
SET col_name={expr | DEFAULT}, ...
[ ON DUPLICATE KEY UPDATE col_name=expr, ... ]
```

Or:

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name [(col_name,...)]
SELECT ...
[ ON DUPLICATE KEY UPDATE col_name=expr, ... ]
```

INSERT inserts new rows into an existing table. The **INSERT ... VALUES** and **INSERT ... SET** forms of the statement insert rows based on explicitly specified values. The **INSERT ... SELECT** form inserts rows selected from another table or tables. **INSERT ... SELECT** is discussed further in [Section 12.2.4.1, “INSERT ... SELECT Syntax”](#).

You can use **REPLACE** instead of **INSERT** to overwrite old rows. **REPLACE** is the counterpart to **INSERT IGNORE** in the treatment of new rows that contain unique key values that duplicate old rows: The new rows are used to replace the old rows rather than being discarded. See [Section 12.2.6, “REPLACE Syntax”](#).

tbl_name is the table into which rows should be inserted. The columns for which the statement provides values can be specified as follows:

- You can provide a comma-separated list of column names following the table name. In this case, a value for each named column must be provided by the **VALUES** list or the **SELECT** statement.
- If you do not specify a list of column names for **INSERT ... VALUES** or **INSERT ... SELECT**, values for every column in the table must be provided by the **VALUES** list or the **SELECT** statement. If you do not know the order of the columns in the table, use **DESCRIBE *tbl_name*** to find out.
- The **SET** clause indicates the column names explicitly.

Column values can be given in several ways:

- If you are not running in strict SQL mode, any column not explicitly given a value is set to its default (explicit or implicit) value. For example, if you specify a column list that does not name all the columns in the table, unnamed columns are set to their default values. Default value assignment is described in [Section 10.1.4, “Data Type Default Values”](#). See also [Section 1.9.6.2, “Constraints on Invalid Data”](#).

If you want an **INSERT** statement to generate an error unless you explicitly specify values for all columns that do not have a default value, you should use strict mode. See [Section 5.2.6, “SQL Modes”](#).

- Use the keyword **DEFAULT** to set a column explicitly to its default value. This makes it easier to write **INSERT** statements that assign values to all but a few columns, because it enables you to avoid writing an incomplete **VALUES** list that does not include a value for each column in the table. Otherwise, you would have to write out the list of column names corresponding to each value in the **VALUES** list.

You can also use **DEFAULT(*col_name*)** as a more general form that can be used in expressions to produce a given column's default value.

- If both the column list and the **VALUES** list are empty, **INSERT** creates a row with each column set to its default value:

```
INSERT INTO tbl_name () VALUES();
```

In strict mode, an error occurs if any column doesn't have a default value. Otherwise, MySQL uses the implicit default value for any column that does not have an explicitly defined default.

- You can specify an expression *expr* to provide a column value. This might involve type conversion if the type of the expression does not match the type of the column, and conversion of a given value can result in different inserted values depending on the data type. For example, inserting the string `'1999.0e-2'` into an **INT**, **FLOAT**, **DECIMAL(10,6)**, or **YEAR** column results in the values `1999`, `19.9921`, `19.992100`, and `1999` being inserted, respectively. The reason the value stored in the **INT** and **YEAR** columns is `1999` is that the string-to-integer conversion looks only at as much of the initial part of the string as may be considered a valid integer or year. For the floating-point and fixed-point columns, the string-to-floating-point conversion considers the entire string a valid floating-point value.

An expression *expr* can refer to any column that was set earlier in a value list. For example, you can do this because the value for `col2` refers to `col1`, which has previously been assigned:

```
INSERT INTO tbl_name (col1,col2) VALUES(15,col1*2);
```

But the following is not legal, because the value for `col1` refers to `col2`, which is assigned after `col1`:

```
INSERT INTO tbl_name (col1,col2) VALUES(col2*2,15);
```

One exception involves columns that contain `AUTO_INCREMENT` values. Because the `AUTO_INCREMENT` value is generated after other value assignments, any reference to an `AUTO_INCREMENT` column in the assignment returns a `0`.

`INSERT` statements that use `VALUES` syntax can insert multiple rows. To do this, include multiple lists of column values, each enclosed within parentheses and separated by commas. Example:

```
INSERT INTO tbl_name (a,b,c) VALUES(1,2,3),(4,5,6),(7,8,9);
```

The values list for each row must be enclosed within parentheses. The following statement is illegal because the number of values in the list does not match the number of column names:

```
INSERT INTO tbl_name (a,b,c) VALUES(1,2,3,4,5,6,7,8,9);
```

The rows-affected value for an `INSERT` can be obtained using the `mysql_affected_rows()` C API function. See [Section 25.2.3.1](#), “`mysql_affected_rows()`”.

If you use an `INSERT ... VALUES` statement with multiple value lists or `INSERT ... SELECT`, the statement returns an information string in this format:

```
Records: 100 Duplicates: 0 Warnings: 0
```

Records indicates the number of rows processed by the statement. (This is not necessarily the number of rows actually inserted because **Duplicates** can be non-zero.) **Duplicates** indicates the number of rows that could not be inserted because they would duplicate some existing unique index value. **Warnings** indicates the number of attempts to insert column values that were problematic in some way. Warnings can occur under any of the following conditions:

- Inserting `NULL` into a column that has been declared `NOT NULL`. For multiple-row `INSERT` statements or `INSERT INTO ... SELECT` statements, the column is set to the implicit default value for the column data type. This is `0` for numeric types, the empty string (`' '`) for string types, and the “zero” value for date and time types. `INSERT INTO ... SELECT` statements are handled the same way as multiple-row inserts because the server does not examine the result set from the `SELECT` to see whether it returns a single row. (For a single-row `INSERT`, no warning occurs when `NULL` is inserted into a `NOT NULL` column. Instead, the statement fails with an error.)
- Setting a numeric column to a value that lies outside the column's range. The value is clipped to the closest endpoint of the range.
- Assigning a value such as `'10.34 a'` to a numeric column. The trailing non-numeric text is stripped off and the remaining numeric part is inserted. If the string value has no leading numeric part, the column is set to `0`.
- Inserting a string into a string column (`CHAR`, `VARCHAR`, `TEXT`, or `BLOB`) that exceeds the column's maximum length. The value is truncated to the column's maximum length.
- Inserting a value into a date or time column that is illegal for the data type. The column is set to the appropriate zero value for the type.

If you are using the C API, the information string can be obtained by invoking the `mysql_info()` function. See [Section 25.2.3.35](#), “`mysql_info()`”.

If `INSERT` inserts a row into a table that has an `AUTO_INCREMENT` column, you can find the value used for that column by using the SQL `LAST_INSERT_ID()` function. From within the C API, use the `mysql_insert_id()` function. However, you should note that the two functions do not always behave identically. The behavior of `INSERT` statements with respect to `AUTO_INCREMENT` columns is discussed further in [Section 11.11.3](#), “[Information Functions](#)”, and [Section 25.2.3.37](#), “`mysql_insert_id()`”.

The `INSERT` statement supports the following modifiers:

- If you use the `DELAYED` keyword, the server puts the row or rows to be inserted into a buffer, and the client issuing the `INSERT`

DELAYED statement can then continue immediately. If the table is in use, the server holds the rows. When the table is free, the server begins inserting rows, checking periodically to see whether there are any new read requests for the table. If there are, the delayed row queue is suspended until the table becomes free again. See [Section 12.2.4.2, “INSERT DELAYED Syntax”](#).

DELAYED is ignored with **INSERT ... SELECT** or **INSERT ... ON DUPLICATE KEY UPDATE**.

- If you use the **LOW_PRIORITY** keyword, execution of the **INSERT** is delayed until no other clients are reading from the table. This includes other clients that began reading while existing clients are reading, and while the **INSERT LOW_PRIORITY** statement is waiting. It is possible, therefore, for a client that issues an **INSERT LOW_PRIORITY** statement to wait for a very long time (or even forever) in a read-heavy environment. (This is in contrast to **INSERT DELAYED**, which lets the client continue at once. Note that **LOW_PRIORITY** should normally not be used with **MyISAM** tables because doing so disables concurrent inserts. See [Section 6.3.3, “Concurrent Inserts”](#)).

If you specify **HIGH_PRIORITY**, it overrides the effect of the `--low-priority-updates` option if the server was started with that option. It also causes concurrent inserts not to be used. See [Section 6.3.3, “Concurrent Inserts”](#).

LOW_PRIORITY and **HIGH_PRIORITY** affect only storage engines that use only table-level locking (**MyISAM**, **MEMORY**, **MERGE**).

- If you use the **IGNORE** keyword, errors that occur while executing the **INSERT** statement are treated as warnings instead. For example, without **IGNORE**, a row that duplicates an existing **UNIQUE** index or **PRIMARY KEY** value in the table causes a duplicate-key error and the statement is aborted. With **IGNORE**, the row still is not inserted, but no error is issued. Data conversions that would trigger errors abort the statement if **IGNORE** is not specified. With **IGNORE**, invalid values are adjusted to the closest values and inserted; warnings are produced but the statement does not abort. You can determine with the `mysql_info()` C API function how many rows were actually inserted into the table.
- If you specify **ON DUPLICATE KEY UPDATE**, and a row is inserted that would cause a duplicate value in a **UNIQUE** index or **PRIMARY KEY**, an **UPDATE** of the old row is performed. See [Section 12.2.4.3, “INSERT ... ON DUPLICATE KEY UPDATE Syntax”](#).

12.2.4.1. INSERT ... SELECT Syntax

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name [(col_name,...)]
SELECT ...
[ ON DUPLICATE KEY UPDATE col_name=expr, ... ]
```

With **INSERT ... SELECT**, you can quickly insert many rows into a table from one or many tables. For example:

```
INSERT INTO tbl_temp2 (fld_id)
SELECT tbl_temp1.fld_order_id
FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

The following conditions hold for a **INSERT ... SELECT** statements:

- Specify **IGNORE** to ignore rows that would cause duplicate-key violations.
- **DELAYED** is ignored with **INSERT ... SELECT**.
- The target table of the **INSERT** statement may appear in the **FROM** clause of the **SELECT** part of the query. (This was not possible in some older versions of MySQL.) In this case, MySQL creates a temporary table to hold the rows from the **SELECT** and then inserts those rows into the target table. However, it remains true that you cannot use **INSERT INTO t ... SELECT ... FROM t** when **t** is a **TEMPORARY** table, because **TEMPORARY** tables cannot be referred to twice in the same statement (see [Section B.1.7.3, “TEMPORARY TABLE Problems”](#)).
- **AUTO_INCREMENT** columns work as usual.
- To ensure that the binary log can be used to re-create the original tables, MySQL does not allow concurrent inserts for **INSERT ... SELECT** statements.
- Currently, you cannot insert into a table and select from the same table in a subquery.
- To avoid ambiguous column reference problems when the **SELECT** and the **INSERT** refer to the same table, provide a unique alias for each table used in the **SELECT** part, and qualify column names in that part with the appropriate alias.

In the values part of **ON DUPLICATE KEY UPDATE**, you can refer to columns in other tables, as long as you do not use **GROUP BY** in the **SELECT** part. One side effect is that you must qualify non-unique column names in the values part.

12.2.4.2. **INSERT DELAYED** Syntax

```
INSERT DELAYED ...
```

The **DELAYED** option for the **INSERT** statement is a MySQL extension to standard SQL that is very useful if you have clients that cannot or need not wait for the **INSERT** to complete. This is a common situation when you use MySQL for logging and you also periodically run **SELECT** and **UPDATE** statements that take a long time to complete.

When a client uses **INSERT DELAYED**, it gets an okay from the server at once, and the row is queued to be inserted when the table is not in use by any other thread.

Another major benefit of using **INSERT DELAYED** is that inserts from many clients are bundled together and written in one block. This is much faster than performing many separate inserts.

Note that **INSERT DELAYED** is slower than a normal **INSERT** if the table is not otherwise in use. There is also the additional overhead for the server to handle a separate thread for each table for which there are delayed rows. This means that you should use **INSERT DELAYED** only when you are really sure that you need it.

The queued rows are held only in memory until they are inserted into the table. This means that if you terminate **mysqld** forcibly (for example, with **kill -9**) or if **mysqld** dies unexpectedly, *any queued rows that have not been written to disk are lost*.

There are some constraints on the use of **DELAYED**:

- **INSERT DELAYED** works only with **MyISAM**, **MEMORY**, **ARCHIVE**, and (as of MySQL 5.1.19) **BLACKHOLE** tables. See [Section 13.4, “The MyISAM Storage Engine”](#), [Section 13.7, “The MEMORY \(HEAP\) Storage Engine”](#), [Section 13.10, “The ARCHIVE Storage Engine”](#), and [Section 13.12, “The BLACKHOLE Storage Engine”](#).
- For **MyISAM** tables, if there are no free blocks in the middle of the data file, concurrent **SELECT** and **INSERT** statements are supported. Under these circumstances, you very seldom need to use **INSERT DELAYED** with **MyISAM**.
- **INSERT DELAYED** should be used only for **INSERT** statements that specify value lists. The server ignores **DELAYED** for **INSERT ... SELECT** or **INSERT ... ON DUPLICATE KEY UPDATE** statements.
- Because the **INSERT DELAYED** statement returns immediately, before the rows are inserted, you cannot use **LAST_INSERT_ID()** to get the **AUTO_INCREMENT** value that the statement might generate.
- **DELAYED** rows are not visible to **SELECT** statements until they actually have been inserted.
- **DELAYED** is ignored on slave replication servers because it could cause the slave to have different data than the master.
- Pending **INSERT DELAYED** statements are lost if a table is write locked and **ALTER TABLE** is used to modify the table structure.
- **INSERT DELAYED** is not supported for views.

The following describes in detail what happens when you use the **DELAYED** option to **INSERT** or **REPLACE**. In this description, the “thread” is the thread that received an **INSERT DELAYED** statement and “handler” is the thread that handles all **INSERT DELAYED** statements for a particular table.

- When a thread executes a **DELAYED** statement for a table, a handler thread is created to process all **DELAYED** statements for the table, if no such handler already exists.
- The thread checks whether the handler has previously acquired a **DELAYED** lock; if not, it tells the handler thread to do so. The **DELAYED** lock can be obtained even if other threads have a **READ** or **WRITE** lock on the table. However, the handler waits for all **ALTER TABLE** locks or **FLUSH TABLES** statements to finish, to ensure that the table structure is up to date.
- The thread executes the **INSERT** statement, but instead of writing the row to the table, it puts a copy of the final row into a queue that is managed by the handler thread. Any syntax errors are noticed by the thread and reported to the client program.
- The client cannot obtain from the server the number of duplicate rows or the **AUTO_INCREMENT** value for the resulting row, be-

cause the `INSERT` returns before the insert operation has been completed. (If you use the C API, the `mysql_info()` function does not return anything meaningful, for the same reason.)

- The binary log is updated by the handler thread when the row is inserted into the table. In case of multiple-row inserts, the binary log is updated when the first row is inserted.
- Each time that `delayed_insert_limit` rows are written, the handler checks whether any `SELECT` statements are still pending. If so, it allows these to execute before continuing.
- When the handler has no more rows in its queue, the table is unlocked. If no new `INSERT DELAYED` statements are received within `delayed_insert_timeout` seconds, the handler terminates.
- If more than `delayed_queue_size` rows are pending in a specific handler queue, the thread requesting `INSERT DELAYED` waits until there is room in the queue. This is done to ensure that `mysqld` does not use all memory for the delayed memory queue.
- The handler thread shows up in the MySQL process list with `delayed_insert` in the `Command` column. It is killed if you execute a `FLUSH TABLES` statement or kill it with `KILL thread_id`. However, before exiting, it first stores all queued rows into the table. During this time it does not accept any new `INSERT` statements from other threads. If you execute an `INSERT DELAYED` statement after this, a new handler thread is created.

Note that this means that `INSERT DELAYED` statements have higher priority than normal `INSERT` statements if there is an `INSERT DELAYED` handler running. Other update statements have to wait until the `INSERT DELAYED` queue is empty, someone terminates the handler thread (with `KILL thread_id`), or someone executes a `FLUSH TABLES`.

- The following status variables provide information about `INSERT DELAYED` statements:

Status Variable	Meaning
<code>Delayed_insert_threads</code>	Number of handler threads
<code>Delayed_writes</code>	Number of rows written with <code>INSERT DELAYED</code>
<code>Not_flushed_delayed_rows</code>	Number of rows waiting to be written

You can view these variables by issuing a `SHOW STATUS` statement or by executing a `mysqladmin extended-status` command.

12.2.4.3. `INSERT ... ON DUPLICATE KEY UPDATE` Syntax

If you specify `ON DUPLICATE KEY UPDATE`, and a row is inserted that would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`, an `UPDATE` of the old row is performed. For example, if column `a` is declared as `UNIQUE` and contains the value `1`, the following two statements have identical effect:

```
INSERT INTO table (a,b,c) VALUES (1,2,3)
ON DUPLICATE KEY UPDATE c=c+1;

UPDATE table SET c=c+1 WHERE a=1;
```

The rows-affected value is 1 if the row is inserted as a new record and 2 if an existing record is updated.

If column `b` is also unique, the `INSERT` is equivalent to this `UPDATE` statement instead:

```
UPDATE table SET c=c+1 WHERE a=1 OR b=2 LIMIT 1;
```

If `a=1 OR b=2` matches several rows, only *one* row is updated. In general, you should try to avoid using an `ON DUPLICATE KEY` clause on tables with multiple unique indexes.

You can use the `VALUES(col_name)` function in the `UPDATE` clause to refer to column values from the `INSERT` portion of the `INSERT ... UPDATE` statement. In other words, `VALUES(col_name)` in the `UPDATE` clause refers to the value of `col_name` that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The `VALUES()` function is meaningful only in `INSERT ... UPDATE` statements and returns `NULL` otherwise. Example:

```
INSERT INTO table (a,b,c) VALUES (1,2,3),(4,5,6)
ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

That statement is identical to the following two statements:

```
INSERT INTO table (a,b,c) VALUES (1,2,3)
ON DUPLICATE KEY UPDATE c=3;
INSERT INTO table (a,b,c) VALUES (4,5,6)
ON DUPLICATE KEY UPDATE c=9;
```

If a table contains an `AUTO_INCREMENT` column and `INSERT ... UPDATE` inserts a row, the `LAST_INSERT_ID()` function returns the `AUTO_INCREMENT` value. If the statement updates a row instead, `LAST_INSERT_ID()` is not meaningful. However, you can work around this by using `LAST_INSERT_ID(expr)`. Suppose that `id` is the `AUTO_INCREMENT` column. To make `LAST_INSERT_ID()` meaningful for updates, insert rows as follows:

```
INSERT INTO table (a,b,c) VALUES (1,2,3)
ON DUPLICATE KEY UPDATE id=LAST_INSERT_ID(id), c=3;
```

The `DELAYED` option is ignored when you use `ON DUPLICATE KEY UPDATE`.

12.2.5. LOAD DATA INFILE Syntax

```
LOAD DATA [LOW_PRIORITY | CONCURRENT] [LOCAL] INFILE 'file_name'
[REPLACE | IGNORE]
INTO TABLE tbl_name
[CHARACTER SET charset_name]
[FIELDS
  [TERMINATED BY 'string']
  [[OPTIONALLY] ENCLOSED BY 'char']
  [ESCAPED BY 'char']
]
[LINES
  [STARTING BY 'string']
  [TERMINATED BY 'string']
]
[IGNORE number LINES]
[(col_name_or_user_var,...)]
[SET col_name = expr,...]
```

The `LOAD DATA INFILE` statement reads rows from a text file into a table at a very high speed. The filename must be given as a literal string.

`LOAD DATA INFILE` is the complement of `SELECT ... INTO OUTFILE`. (See [Section 12.2.7, “SELECT Syntax”](#).) To write data from a table to a file, use `SELECT ... INTO OUTFILE`. To read the file back into a table, use `LOAD DATA INFILE`. The syntax of the `FIELDS` and `LINES` clauses is the same for both statements. Both clauses are optional, but `FIELDS` must precede `LINES` if both are specified.

For more information about the efficiency of `INSERT` versus `LOAD DATA INFILE` and speeding up `LOAD DATA INFILE`, see [Section 6.2.17, “Speed of INSERT Statements”](#).

The character set indicated by the `character_set_database` system variable is used to interpret the information in the file. `SET NAMES` and the setting of `character_set_client` do not affect interpretation of input. Beginning with MySQL 5.1.17, if the contents of the input file use a character set that differs from the default, it is possible (and usually preferable) to use the `CHARACTER SET` clause to specify the character set of the file.

`LOAD DATA INFILE` interprets all fields in the file as having the same character set, regardless of the data types of the columns into which field values are loaded. For proper interpretation of file contents, you must ensure that it was written with the correct character set. For example, if you write a data file with `mysqldump -T` or by issuing a `SELECT ... INTO OUTFILE` statement in `mysql`, be sure to use a `--default-character-set` option with `mysqldump` or `mysql` so that output is written in the character set to be used when the file is loaded with `LOAD DATA INFILE`.

Note that it is currently not possible to load data files that use the `ucs2` character set.

As of MySQL 5.1.6, the `character_set_filesystem` system variable controls the interpretation of the filename.

You can also load data files by using the `mysqlimport` utility; it operates by sending a `LOAD DATA INFILE` statement to the server. The `--local` option causes `mysqlimport` to read data files from the client host. You can specify the `--compress` option to get better performance over slow networks if the client and server support the compressed protocol. See [Section 7.15, “mysqlimport — A Data Import Program”](#).

If you use `LOW_PRIORITY`, execution of the `LOAD DATA` statement is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (`MyISAM`, `MEMORY`, `MERGE`).

If you specify **CONCURRENT** with a **MyISAM** table that satisfies the condition for concurrent inserts (that is, it contains no free blocks in the middle), other threads can retrieve data from the table while **LOAD DATA** is executing. Using this option affects the performance of **LOAD DATA** a bit, even if no other thread is using the table at the same time.

The **LOCAL** keyword, if specified, is interpreted with respect to the client end of the connection:

- If **LOCAL** is specified, the file is read by the client program on the client host and sent to the server. The file can be given as a full pathname to specify its exact location. If given as a relative pathname, the name is interpreted relative to the directory in which the client program was started.
- If **LOCAL** is not specified, the file must be located on the server host and is read directly by the server. The server uses the following rules to locate the file:
 - If the filename is an absolute pathname, the server uses it as given.
 - If the filename is a relative pathname with one or more leading components, the server searches for the file relative to the server's data directory.
 - If a filename with no leading components is given, the server looks for the file in the database directory of the default database.

Note that, in the non-**LOCAL** case, these rules mean that a file named as `./myfile.txt` is read from the server's data directory, whereas the file named as `myfile.txt` is read from the database directory of the default database. For example, if **db1** is the default database, the following **LOAD DATA** statement reads the file `data.txt` from the database directory for **db1**, even though the statement explicitly loads the file into a table in the **db2** database:

```
LOAD DATA INFILE 'data.txt' INTO TABLE db2.my_table;
```

Windows pathnames are specified using forward slashes rather than backslashes. If you do use backslashes, you must double them.

For security reasons, when reading text files located on the server, the files must either reside in the database directory or be readable by all. Also, to use **LOAD DATA INFILE** on server files, you must have the **FILE** privilege. See [Section 5.7.3, “Privileges Provided by MySQL”](#).

Using **LOCAL** is a bit slower than letting the server access the files directly, because the contents of the file must be sent over the connection by the client to the server. On the other hand, you do not need the **FILE** privilege to load local files.

LOCAL works only if your server and your client both have been enabled to allow it. For example, if `mysqld` was started with `-local-infile=0`, **LOCAL** does not work. See [Section 5.6.4, “Security Issues with LOAD DATA LOCAL”](#).

On Unix, if you need **LOAD DATA** to read from a pipe, you can use the following technique (here we load the listing of the `/` directory into a table):

```
mkfifo /mysql/db/x/x
chmod 666 /mysql/db/x/x
find / -ls > /mysql/db/x/x &
mysql -e "LOAD DATA INFILE 'x' INTO TABLE x" x
```

Note that you must run the command that generates the data to be loaded and the `mysql` commands either on separate terminals, or run the data generation process in the background (as shown in the preceding example). If you do not do this, the pipe will block until data is read by the `mysql` process.

The **REPLACE** and **IGNORE** keywords control handling of input rows that duplicate existing rows on unique key values:

- If you specify **REPLACE**, input rows replace existing rows. In other words, rows that have the same value for a primary key or unique index as an existing row. See [Section 12.2.6, “REPLACE Syntax”](#).
- If you specify **IGNORE**, input rows that duplicate an existing row on a unique key value are skipped. If you do not specify either option, the behavior depends on whether the **LOCAL** keyword is specified. Without **LOCAL**, an error occurs when a duplicate key value is found, and the rest of the text file is ignored. With **LOCAL**, the default behavior is the same as if **IGNORE** is specified; this is because the server has no way to stop transmission of the file in the middle of the operation.

If you want to ignore foreign key constraints during the load operation, you can issue a **SET FOREIGN_KEY_CHECKS=0** statement

before executing `LOAD DATA`.

If you use `LOAD DATA INFILE` on an empty `MyISAM` table, all non-unique indexes are created in a separate batch (as for `REPAIR TABLE`). Normally, this makes `LOAD DATA INFILE` much faster when you have many indexes. In some extreme cases, you can create the indexes even faster by turning them off with `ALTER TABLE ... DISABLE KEYS` before loading the file into the table and using `ALTER TABLE ... ENABLE KEYS` to re-create the indexes after loading the file. See [Section 6.2.17, “Speed of INSERT Statements”](#).

For both the `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE` statements, the syntax of the `FIELDS` and `LINES` clauses is the same. Both clauses are optional, but `FIELDS` must precede `LINES` if both are specified.

If you specify a `FIELDS` clause, each of its subclauses (`TERMINATED BY`, `[OPTIONALLY] ENCLOSED BY`, and `ESCAPED BY`) is also optional, except that you must specify at least one of them.

If you specify no `FIELDS` clause, the defaults are the same as if you had written this:

```
FIELDS TERMINATED BY '\t' ENCLOSED BY '' ESCAPED BY '\\'
```

If you specify no `LINES` clause, the defaults are the same as if you had written this:

```
LINES TERMINATED BY '\n' STARTING BY ''
```

In other words, the defaults cause `LOAD DATA INFILE` to act as follows when reading input:

- Look for line boundaries at newlines.
- Do not skip over any line prefix.
- Break lines into fields at tabs.
- Do not expect fields to be enclosed within any quoting characters.
- Interpret occurrences of tab, newline, or `\` preceded by `\` as literal characters that are part of field values.

Conversely, the defaults cause `SELECT ... INTO OUTFILE` to act as follows when writing output:

- Write tabs between fields.
- Do not enclose fields within any quoting characters.
- Use `\` to escape instances of tab, newline, or `\` that occur within field values.
- Write newlines at the ends of lines.

Backslash is the MySQL escape character within strings, so to write `FIELDS ESCAPED BY '\\'`, you must specify two backslashes for the value to be interpreted as a single backslash.

Note

If you have generated the text file on a Windows system, you might have to use `LINES TERMINATED BY '\r\n'` to read the file properly, because Windows programs typically use two characters as a line terminator. Some programs, such as `WordPad`, might use `\r` as a line terminator when writing files. To read such files, use `LINES TERMINATED BY '\r'`.

If all the lines you want to read in have a common prefix that you want to ignore, you can use `LINES STARTING BY 'prefix_string'` to skip over the prefix, *and anything before it*. If a line does not include the prefix, the entire line is skipped. Suppose that you issue the following statement:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test
FIELDS TERMINATED BY ',' LINES STARTING BY 'xxx';
```

If the data file looks like this:

```
xxx"abc",1
something xxx"def",2
"ghi",3
```

The resulting rows will be ("abc", 1) and ("def", 2). The third row in the file is skipped because it does not contain the prefix.

The **IGNORE number LINES** option can be used to ignore lines at the start of the file. For example, you can use **IGNORE 1 LINES** to skip over an initial header line containing column names:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test IGNORE 1 LINES;
```

When you use **SELECT ... INTO OUTFILE** in tandem with **LOAD DATA INFILE** to write data from a database into a file and then read the file back into the database later, the field- and line-handling options for both statements must match. Otherwise, **LOAD DATA INFILE** will not interpret the contents of the file properly. Suppose that you use **SELECT ... INTO OUTFILE** to write a file with fields delimited by commas:

```
SELECT * INTO OUTFILE 'data.txt'
  FIELDS TERMINATED BY ','
FROM table2;
```

To read the comma-delimited file back in, the correct statement would be:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
  FIELDS TERMINATED BY ',';
```

If instead you tried to read in the file with the statement shown following, it wouldn't work because it instructs **LOAD DATA INFILE** to look for tabs between fields:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
  FIELDS TERMINATED BY '\t';
```

The likely result is that each input line would be interpreted as a single field.

LOAD DATA INFILE can be used to read files obtained from external sources. For example, many programs can export data in comma-separated values (CSV) format, such that lines have fields separated by commas and enclosed within double quotes. If lines in such a file are terminated by newlines, the statement shown here illustrates the field- and line-handling options you would use to load the file:

```
LOAD DATA INFILE 'data.txt' INTO TABLE tbl_name
  FIELDS TERMINATED BY ',' ENCLOSED BY '"'
  LINES TERMINATED BY '\n';
```

If the input values are not necessarily enclosed within quotes, use **OPTIONALLY** before the **ENCLOSED BY** keywords.

Any of the field- or line-handling options can specify an empty string (''). If not empty, the **FIELDS [OPTIONALLY] ENCLOSED BY** and **FIELDS ESCAPED BY** values must be a single character. The **FIELDS TERMINATED BY**, **LINES STARTING BY**, and **LINES TERMINATED BY** values can be more than one character. For example, to write lines that are terminated by carriage return/linefeed pairs, or to read a file containing such lines, specify a **LINES TERMINATED BY '\r\n'** clause.

To read a file containing jokes that are separated by lines consisting of **%%**, you can do this

```
CREATE TABLE jokes
(a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
 joke TEXT NOT NULL);
LOAD DATA INFILE '/tmp/jokes.txt' INTO TABLE jokes
  FIELDS TERMINATED BY ','
  LINES TERMINATED BY '\n%%\n' (joke);
```

FIELDS [OPTIONALLY] ENCLOSED BY controls quoting of fields. For output (**SELECT ... INTO OUTFILE**), if you omit the word **OPTIONALLY**, all fields are enclosed by the **ENCLOSED BY** character. An example of such output (using a comma as the field delimiter) is shown here:

```
"1","a string","100.20"
"2","a string containing a , comma","102.20"
"3","a string containing a \" quote","102.20"
"4","a string containing a \", quote and comma","102.20"
```

If you specify **OPTIONALLY**, the **ENCLOSED BY** character is used only to enclose values from columns that have a string data type (such as **CHAR**, **BINARY**, **TEXT**, or **ENUM**):

```
1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a \" quote",102.20
4,"a string containing a \", quote and comma",102.20
```

Note that occurrences of the **ENCLOSED BY** character within a field value are escaped by prefixing them with the **ESCAPED BY** character. Also note that if you specify an empty **ESCAPED BY** value, it is possible to inadvertently generate output that cannot be read properly by **LOAD DATA INFILE**. For example, the preceding output just shown would appear as follows if the escape character is empty. Observe that the second field in the fourth line contains a comma following the quote, which (erroneously) appears to terminate the field:

```
1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a " quote",102.20
4,"a string containing a ", quote and comma",102.20
```

For input, the **ENCLOSED BY** character, if present, is stripped from the ends of field values. (This is true regardless of whether **OPTIONALLY** is specified; **OPTIONALLY** has no effect on input interpretation.) Occurrences of the **ENCLOSED BY** character preceded by the **ESCAPED BY** character are interpreted as part of the current field value.

If the field begins with the **ENCLOSED BY** character, instances of that character are recognized as terminating a field value only if followed by the field or line **TERMINATED BY** sequence. To avoid ambiguity, occurrences of the **ENCLOSED BY** character within a field value can be doubled and are interpreted as a single instance of the character. For example, if **ENCLOSED BY '''** is specified, quotes are handled as shown here:

```
"The ""BIG"" boss" -> The "BIG" boss
The "BIG" boss    -> The "BIG" boss
The ""BIG"" boss  -> The "BIG" boss
```

FIELDS ESCAPED BY controls how to write or read special characters. If the **FIELDS ESCAPED BY** character is not empty, it is used to prefix the following characters on output:

- The **FIELDS ESCAPED BY** character
- The **FIELDS [OPTIONALLY] ENCLOSED BY** character
- The first character of the **FIELDS TERMINATED BY** and **LINES TERMINATED BY** values
- ASCII 0 (what is actually written following the escape character is ASCII '0', not a zero-valued byte)

If the **FIELDS ESCAPED BY** character is empty, no characters are escaped and **NULL** is output as **NULL**, not **\N**. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

For input, if the **FIELDS ESCAPED BY** character is not empty, occurrences of that character are stripped and the following character is taken literally as part of a field value. Some two-character sequences that are exceptions, where the first character is the escape character. These sequences are shown in the following table (using '\' for the escape character). The rules for **NULL** handling are described later in this section.

\0	An ASCII 0 (NUL) character
\b	A backspace character
\n	A newline (linefeed) character
\r	A carriage return character
\t	A tab character.
\Z	ASCII 26 (Control-Z)
\N	NULL

For more information about ‘\’-escape syntax, see [Section 8.1, “Literal Values”](#).

In certain cases, field- and line-handling options interact:

- If **LINES TERMINATED BY** is an empty string and **FIELDS TERMINATED BY** is non-empty, lines are also terminated with **FIELDS TERMINATED BY**.
- If the **FIELDS TERMINATED BY** and **FIELDS ENCLOSED BY** values are both empty (' '), a fixed-row (non-delimited) format is used. With fixed-row format, no delimiters are used between fields (but you can still have a line terminator). Instead, column values are read and written using a field width wide enough to hold all values in the field. For **TINYINT**, **SMALLINT**, **MEDIUMINT**, **INT**, and **BIGINT**, the field widths are 4, 6, 8, 11, and 20, respectively, no matter what the declared display width is.

LINES TERMINATED BY is still used to separate lines. If a line does not contain all fields, the rest of the columns are set to their default values. If you do not have a line terminator, you should set this to ' '. In this case, the text file must contain all fields for each row.

Fixed-row format also affects handling of **NULL** values, as described later. Note that fixed-size format does not work if you are using a multi-byte character set.

Handling of **NULL** values varies according to the **FIELDS** and **LINES** options in use:

- For the default **FIELDS** and **LINES** values, **NULL** is written as a field value of **\N** for output, and a field value of **\N** is read as **NULL** for input (assuming that the **ESCAPED BY** character is ‘\’).
- If **FIELDS ENCLOSED BY** is not empty, a field containing the literal word **NULL** as its value is read as a **NULL** value. This differs from the word **NULL** enclosed within **FIELDS ENCLOSED BY** characters, which is read as the string 'NULL'.
- If **FIELDS ESCAPED BY** is empty, **NULL** is written as the word **NULL**.
- With fixed-row format (which is used when **FIELDS TERMINATED BY** and **FIELDS ENCLOSED BY** are both empty), **NULL** is written as an empty string. Note that this causes both **NULL** values and empty strings in the table to be indistinguishable when written to the file because both are written as empty strings. If you need to be able to tell the two apart when reading the file back in, you should not use fixed-row format.

An attempt to load **NULL** into a **NOT NULL** column causes assignment of the implicit default value for the column's data type and a warning, or an error in strict SQL mode. Implicit default values are discussed in [Section 10.1.4, “Data Type Default Values”](#).

Some cases are not supported by **LOAD DATA INFILE**:

- Fixed-size rows (**FIELDS TERMINATED BY** and **FIELDS ENCLOSED BY** both empty) and **BLOB** or **TEXT** columns.
- If you specify one separator that is the same as or a prefix of another, **LOAD DATA INFILE** cannot interpret the input properly. For example, the following **FIELDS** clause would cause problems:

```
FIELDS TERMINATED BY ' ' ENCLOSED BY ' '
```

- If **FIELDS ESCAPED BY** is empty, a field value that contains an occurrence of **FIELDS ENCLOSED BY** or **LINES TERMINATED BY** followed by the **FIELDS TERMINATED BY** value causes **LOAD DATA INFILE** to stop reading a field or line too early. This happens because **LOAD DATA INFILE** cannot properly determine where the field or line value ends.

The following example loads all columns of the **persondata** table:

```
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata;
```

By default, when no column list is provided at the end of the **LOAD DATA INFILE** statement, input lines are expected to contain a field for each table column. If you want to load only some of a table's columns, specify a column list:

```
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata (col1,col2,...);
```

You must also specify a column list if the order of the fields in the input file differs from the order of the columns in the table. Otherwise, MySQL cannot tell how to match input fields with table columns.

The column list can contain either column names or user variables. With user variables, the **SET** clause enables you to perform transformations on their values before assigning the result to columns.

User variables in the **SET** clause can be used in several ways. The following example uses the first input column directly for the value of `t1.column1`, and assigns the second input column to a user variable that is subjected to a division operation before being used for the value of `t1.column2`:

```
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, @var1)
  SET column2 = @var1/100;
```

The **SET** clause can be used to supply values not derived from the input file. The following statement sets `column3` to the current date and time:

```
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, column2)
  SET column3 = CURRENT_TIMESTAMP;
```

You can also discard an input value by assigning it to a user variable and not assigning the variable to a table column:

```
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, @dummy, column2, @dummy, column3);
```

Use of the column/variable list and **SET** clause is subject to the following restrictions:

- Assignments in the **SET** clause should have only column names on the left hand side of assignment operators.
- You can use subqueries in the right hand side of **SET** assignments. A subquery that returns a value to be assigned to a column may be a scalar subquery only. Also, you cannot use a subquery to select from the table that is being loaded.
- Lines ignored by an **IGNORE** clause are not processed for the column/variable list or **SET** clause.
- User variables cannot be used when loading data with fixed-row format because user variables do not have a display width.

When processing an input line, **LOAD DATA** splits it into fields and uses the values according to the column/variable list and the **SET** clause, if they are present. Then the resulting row is inserted into the table. If there are **BEFORE INSERT** or **AFTER INSERT** triggers for the table, they are activated before or after inserting the row, respectively.

If an input line has too many fields, the extra fields are ignored and the number of warnings is incremented.

If an input line has too few fields, the table columns for which input fields are missing are set to their default values. Default value assignment is described in [Section 10.1.4, “Data Type Default Values”](#).

An empty field value is interpreted differently than if the field value is missing:

- For string types, the column is set to the empty string.
- For numeric types, the column is set to 0.
- For date and time types, the column is set to the appropriate “zero” value for the type. See [Section 10.3, “Date and Time Types”](#).

These are the same values that result if you assign an empty string explicitly to a string, numeric, or date or time type explicitly in an **INSERT** or **UPDATE** statement.

TIMESTAMP columns are set to the current date and time only if there is a **NULL** value for the column (that is, `\N`) and the column is not declared to allow **NULL** values, or if the **TIMESTAMP** column's default value is the current timestamp and it is omitted from the field list when a field list is specified.

LOAD DATA INFILE regards all input as strings, so you cannot use numeric values for **ENUM** or **SET** columns the way you can with **INSERT** statements. All **ENUM** and **SET** values must be specified as strings.

BIT values cannot be loaded using binary notation (for example, `b'011010'`). To work around this, specify the values as regular integers and use the **SET** clause to convert them so that MySQL performs a numeric type conversion and loads them into the **BIT** column properly:

```
shell> cat /tmp/bit_test.txt
2
127
shell> mysql test
mysql> LOAD DATA INFILE '/tmp/bit_test.txt'
-> INTO TABLE bit_test (@var1) SET b= CAST(@var1 AS UNSIGNED);
Query OK, 2 rows affected (0.00 sec)
Records: 2 Deleted: 0 Skipped: 0 Warnings: 0

mysql> SELECT BIN(b+0) FROM bit_test;
+-----+
| bin(b+0) |
+-----+
| 10      |
| 1111111 |
+-----+
2 rows in set (0.00 sec)
```

When the **LOAD DATA INFILE** statement finishes, it returns an information string in the following format:

```
Records: 1 Deleted: 0 Skipped: 0 Warnings: 0
```

If you are using the C API, you can get information about the statement by calling the `mysql_info()` function. See [Section 25.2.3.35, “mysql_info\(\)”](#).

Warnings occur under the same circumstances as when values are inserted via the **INSERT** statement (see [Section 12.2.4, “INSERT Syntax”](#)), except that **LOAD DATA INFILE** also generates warnings when there are too few or too many fields in the input row. The warnings are not stored anywhere; the number of warnings can be used only as an indication of whether everything went well.

You can use **SHOW WARNINGS** to get a list of the first `max_error_count` warnings as information about what went wrong. See [Section 12.5.4.32, “SHOW WARNINGS Syntax”](#).

12.2.6. REPLACE Syntax

```
REPLACE [LOW_PRIORITY | DELAYED]
[INTO] tbl_name [(col_name,...)]
VALUES ({expr | DEFAULT},...),(...),...
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
[INTO] tbl_name
SET col_name={expr | DEFAULT}, ...
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
[INTO] tbl_name [(col_name,...)]
SELECT ...
```

REPLACE works exactly like **INSERT**, except that if an old row in the table has the same value as a new row for a **PRIMARY KEY** or a **UNIQUE** index, the old row is deleted before the new row is inserted. See [Section 12.2.4, “INSERT Syntax”](#).

REPLACE is a MySQL extension to the SQL standard. It either inserts, or *deletes* and inserts. For another MySQL extension to standard SQL — that either inserts or *updates* — see [Section 12.2.4.3, “INSERT ... ON DUPLICATE KEY UPDATE Syntax”](#).

Note that unless the table has a **PRIMARY KEY** or **UNIQUE** index, using a **REPLACE** statement makes no sense. It becomes equivalent to **INSERT**, because there is no index to be used to determine whether a new row duplicates another.

Values for all columns are taken from the values specified in the **REPLACE** statement. Any missing columns are set to their default values, just as happens for **INSERT**. You cannot refer to values from the current row and use them in the new row. If you use an assignment such as `SET col_name = col_name + 1`, the reference to the column name on the right hand side is treated as

`col_name`), so the assignment is equivalent to `SET col_name = DEFAULT(col_name) + 1`.

To use `REPLACE`, you must have both the `INSERT` and `DELETE` privileges for the table.

The `REPLACE` statement returns a count to indicate the number of rows affected. This is the sum of the rows deleted and inserted. If the count is 1 for a single-row `REPLACE`, a row was inserted and no rows were deleted. If the count is greater than 1, one or more old rows were deleted before the new row was inserted. It is possible for a single row to replace more than one old row if the table contains multiple unique indexes and the new row duplicates values for different old rows in different unique indexes.

The affected-rows count makes it easy to determine whether `REPLACE` only added a row or whether it also replaced any rows: Check whether the count is 1 (added) or greater (replaced).

If you are using the C API, the affected-rows count can be obtained using the `mysql_affected_rows()` function.

Currently, you cannot replace into a table and select from the same table in a subquery.

MySQL uses the following algorithm for `REPLACE` (and `LOAD DATA ... REPLACE`):

1. Try to insert the new row into the table
2. While the insertion fails because a duplicate-key error occurs for a primary key or unique index:
 - a. Delete from the table the conflicting row that has the duplicate key value
 - b. Try again to insert the new row into the table

12.2.7. SELECT Syntax

```
SELECT
  [ALL | DISTINCT | DISTINCTROW ]
  [HIGH_PRIORITY]
  [STRAIGHT_JOIN]
  [SQL_SMALL_RESULT] [SQL_BIG_RESULT] [SQL_BUFFER_RESULT]
  [SQL_CACHE | SQL_NO_CACHE] [SQL_CALC_FOUND_ROWS]
  select_expr, ...
  [FROM table_references
  [WHERE where_condition]
  [GROUP BY {col_name | expr | position}
  [ASC | DESC], ... [WITH ROLLUP]]
  [HAVING where_condition]
  [ORDER BY {col_name | expr | position}
  [ASC | DESC], ...]
  [LIMIT {[offset,] row_count | row_count OFFSET offset}]
  [PROCEDURE procedure_name(argument_list)]
  [INTO OUTFILE 'file_name' export_options
  | INTO DUMPFILE 'file_name'
  | INTO var_name [, var_name]]
  [FOR UPDATE | LOCK IN SHARE MODE]]
```

`SELECT` is used to retrieve rows selected from one or more tables, and can include `UNION` statements and subqueries. See [Section 12.2.7.3, “UNION Syntax”](#), and [Section 12.2.8, “Subquery Syntax”](#).

The most commonly used clauses of `SELECT` statements are these:

- Each `select_expr` indicates a column that you want to retrieve. There must be at least one `select_expr`.
- `table_references` indicates the table or tables from which to retrieve rows. Its syntax is described in [Section 12.2.7.1, “JOIN Syntax”](#).
- The `WHERE` clause, if given, indicates the condition or conditions that rows must satisfy to be selected. `where_condition` is an expression that evaluates to true for each row to be selected. The statement selects all rows if there is no `WHERE` clause.

In the `WHERE` clause, you can use any of the functions and operators that MySQL supports, except for aggregate (summary) functions. See [Chapter 11, Functions and Operators](#).

`SELECT` can also be used to retrieve rows computed without reference to any table.

For example:

```
mysql> SELECT 1 + 1;
-> 2
```

You are allowed to specify **DUAL** as a dummy table name in situations where no tables are referenced:

```
mysql> SELECT 1 + 1 FROM DUAL;
-> 2
```

DUAL is purely for the convenience of people who require that all **SELECT** statements should have **FROM** and possibly other clauses. MySQL may ignore the clauses. MySQL does not require **FROM DUAL** if no tables are referenced.

In general, clauses used must be given in exactly the order shown in the syntax description. For example, a **HAVING** clause must come after any **GROUP BY** clause and before any **ORDER BY** clause. The exception is that the **INTO** clause can appear either as shown in the syntax description or immediately preceding the **FROM** clause.

- A *select_expr* can be given an alias using **AS alias_name**. The alias is used as the expression's column name and can be used in **GROUP BY**, **ORDER BY**, or **HAVING** clauses. For example:

```
SELECT CONCAT(last_name, ', ', first_name) AS full_name
FROM mytable ORDER BY full_name;
```

The **AS** keyword is optional when aliasing a *select_expr*. The preceding example could have been written like this:

```
SELECT CONCAT(last_name, ', ', first_name) full_name
FROM mytable ORDER BY full_name;
```

However, because the **AS** is optional, a subtle problem can occur if you forget the comma between two *select_expr* expressions: MySQL interprets the second as an alias name. For example, in the following statement, **columnb** is treated as an alias name:

```
SELECT columna columnb FROM mytable;
```

For this reason, it is good practice to be in the habit of using **AS** explicitly when specifying column aliases.

- It is not allowable to use a column alias in a **WHERE** clause, because the column value might not yet be determined when the **WHERE** clause is executed. See [Section B.1.5.4, “Problems with Column Aliases”](#).
- The **FROM table_references** clause indicates the table or tables from which to retrieve rows. If you name more than one table, you are performing a join. For information on join syntax, see [Section 12.2.7.1, “JOIN Syntax”](#). For each table specified, you can optionally specify an alias.

```
tbl_name [[AS] alias] [index_hint]
```

The use of index hints provides the optimizer with information about how to choose indexes during query processing. For a description of the syntax for specifying these hints, see [Section 12.2.7.2, “Index Hint Syntax”](#).

You can use **SET max_seeks_for_key=value** as an alternative way to force MySQL to prefer key scans instead of table scans. See [Section 5.2.3, “System Variables”](#).

- You can refer to a table within the default database as *tbl_name*, or as *db_name.tbl_name* to specify a database explicitly. You can refer to a column as *col_name*, *tbl_name.col_name*, or *db_name.tbl_name.col_name*. You need not specify a *tbl_name* or *db_name.tbl_name* prefix for a column reference unless the reference would be ambiguous. See [Section 8.2.1, “Identifier Qualifiers”](#), for examples of ambiguity that require the more explicit column reference forms.
- A table reference can be aliased using *tbl_name AS alias_name* or *tbl_name alias_name*:

```
SELECT t1.name, t2.salary FROM employee AS t1, info AS t2
WHERE t1.name = t2.name;

SELECT t1.name, t2.salary FROM employee t1, info t2
WHERE t1.name = t2.name;
```

- Columns selected for output can be referred to in **ORDER BY** and **GROUP BY** clauses using column names, column aliases, or column positions. Column positions are integers and begin with 1:

```
SELECT college, region, seed FROM tournament
ORDER BY region, seed;

SELECT college, region AS r, seed AS s FROM tournament
ORDER BY r, s;

SELECT college, region, seed FROM tournament
ORDER BY 2, 3;
```

To sort in reverse order, add the **DESC** (descending) keyword to the name of the column in the **ORDER BY** clause that you are sorting by. The default is ascending order; this can be specified explicitly using the **ASC** keyword.

If **ORDER BY** occurs within a subquery and also is applied in the outer query, the outermost **ORDER BY** takes precedence. For example, results for the following statement are sorted in descending order, not ascending order:

```
(SELECT ... ORDER BY a) ORDER BY a DESC;
```

Use of column positions is deprecated because the syntax has been removed from the SQL standard.

- If you use **GROUP BY**, output rows are sorted according to the **GROUP BY** columns as if you had an **ORDER BY** for the same columns. To avoid the overhead of sorting that **GROUP BY** produces, add **ORDER BY NULL**:

```
SELECT a, COUNT(b) FROM test_table GROUP BY a ORDER BY NULL;
```

- MySQL extends the **GROUP BY** clause so that you can also specify **ASC** and **DESC** after columns named in the clause:

```
SELECT a, COUNT(b) FROM test_table GROUP BY a DESC;
```

- MySQL extends the use of **GROUP BY** to allow selecting fields that are not mentioned in the **GROUP BY** clause. If you are not getting the results that you expect from your query, please read the description of **GROUP BY** found in [Section 11.12, “Functions and Modifiers for Use with GROUP BY Clauses”](#).
- GROUP BY** allows a **WITH ROLLUP** modifier. See [Section 11.12.2, “GROUP BY Modifiers”](#).
- The **HAVING** clause is applied nearly last, just before items are sent to the client, with no optimization. (**LIMIT** is applied after **HAVING**.)

The SQL standard requires that **HAVING** must reference only columns in the **GROUP BY** clause or columns used in aggregate functions. However, MySQL supports an extension to this behavior, and allows **HAVING** to refer to columns in the **SELECT** list and columns in outer subqueries as well.

If the **HAVING** clause refers to a column that is ambiguous, a warning occurs. In the following statement, **col2** is ambiguous because it is used as both an alias and a column name:

```
SELECT COUNT(col1) AS col2 FROM t GROUP BY col2 HAVING col2 = 2;
```

Preference is given to standard SQL behavior, so if a **HAVING** column name is used both in **GROUP BY** and as an aliased column in the output column list, preference is given to the column in the **GROUP BY** column.

- Do not use **HAVING** for items that should be in the **WHERE** clause. For example, do not write the following:

```
SELECT col_name FROM tbl_name HAVING col_name > 0;
```

Write this instead:

```
SELECT col_name FROM tbl_name WHERE col_name > 0;
```

- The **HAVING** clause can refer to aggregate functions, which the **WHERE** clause cannot:

```
SELECT user, MAX(salary) FROM users
GROUP BY user HAVING MAX(salary) > 10;
```

(This did not work in some older versions of MySQL.)

- MySQL allows duplicate column names. That is, there can be more than one *select_expr* with the same name. This is an extension to standard SQL. Because MySQL also allows **GROUP BY** and **HAVING** to refer to *select_expr* values, this can result in an ambiguity:

```
SELECT 12 AS a, a FROM t GROUP BY a;
```

In that statement, both columns have the name *a*. To ensure that the correct column is used for grouping, use different names for each *select_expr*.

- MySQL resolves unqualified column or alias references in **ORDER BY** clauses by searching in the *select_expr* values, then in the columns of the tables in the **FROM** clause. For **GROUP BY** or **HAVING** clauses, it searches the **FROM** clause before searching in the *select_expr* values. (For **GROUP BY** and **HAVING**, this differs from the pre-MySQL 5.0 behavior that used the same rules as for **ORDER BY**.)
- The **LIMIT** clause can be used to constrain the number of rows returned by the **SELECT** statement. **LIMIT** takes one or two numeric arguments, which must both be non-negative integer constants (except when using prepared statements).

With two arguments, the first argument specifies the offset of the first row to return, and the second specifies the maximum number of rows to return. The offset of the initial row is 0 (not 1):

```
SELECT * FROM tbl LIMIT 5,10; # Retrieve rows 6-15
```

To retrieve all rows from a certain offset up to the end of the result set, you can use some large number for the second parameter. This statement retrieves all rows from the 96th row to the last:

```
SELECT * FROM tbl LIMIT 95,18446744073709551615;
```

With one argument, the value specifies the number of rows to return from the beginning of the result set:

```
SELECT * FROM tbl LIMIT 5; # Retrieve first 5 rows
```

In other words, **LIMIT row_count** is equivalent to **LIMIT 0, row_count**.

For prepared statements, you can use placeholders. The following statements will return one row from the *tbl* table:

```
SET @a=1;
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?';
EXECUTE STMT USING @a;
```

The following statements will return the second to sixth row from the *tbl* table:

```
SET @skip=1; SET @numrows=5;
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?, ?';
EXECUTE STMT USING @skip, @numrows;
```

For compatibility with PostgreSQL, MySQL also supports the **LIMIT row_count OFFSET offset** syntax.

If **LIMIT** occurs within a subquery and also is applied in the outer query, the outermost **LIMIT** takes precedence. For example, the following statement produces two rows, not one:

```
(SELECT ... LIMIT 1) LIMIT 2;
```

- The **SELECT ... INTO OUTFILE 'file_name'** form of **SELECT** writes the selected rows to a file. The file is created on the server host, so you must have the **FILE** privilege to use this syntax. *file_name* cannot be an existing file, which among other things prevents files such as */etc/passwd* and database tables from being destroyed. As of MySQL 5.1.6, the **character_set_filesystem** system variable controls the interpretation of the filename.

The **SELECT ... INTO OUTFILE** statement is intended primarily to let you very quickly dump a table to a text file on the server machine. If you want to create the resulting file on some client host other than the server host, you cannot use **SELECT ... INTO OUTFILE**. In that case, you should instead use a command such as **mysql -e "SELECT ..." > file_name** to generate the file on the client host.

`SELECT ... INTO OUTFILE` is the complement of `LOAD DATA INFILE`; the syntax for the *export_options* part of the statement consists of the same `FIELDS` and `LINES` clauses that are used with the `LOAD DATA INFILE` statement. See [Section 12.2.5, “LOAD DATA INFILE Syntax”](#).

`FIELDS ESCAPED BY` controls how to write special characters. If the `FIELDS ESCAPED BY` character is not empty, it is used as a prefix that precedes following characters on output:

- The `FIELDS ESCAPED BY` character
- The `FIELDS [OPTIONALLY] ENCLOSED BY` character
- The first character of the `FIELDS TERMINATED BY` and `LINES TERMINATED BY` values
- ASCII NUL (the zero-valued byte; what is actually written following the escape character is ASCII ‘0’, not a zero-valued byte)

The `FIELDS TERMINATED BY`, `ENCLOSED BY`, `ESCAPED BY`, or `LINES TERMINATED BY` characters *must* be escaped so that you can read the file back in reliably. ASCII NUL is escaped to make it easier to view with some paggers.

The resulting file does not have to conform to SQL syntax, so nothing else need be escaped.

If the `FIELDS ESCAPED BY` character is empty, no characters are escaped and `NULL` is output as `NULL`, not `\N`. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

Here is an example that produces a file in the comma-separated values (CSV) format used by many programs:

```
SELECT a,b,a+b INTO OUTFILE '/tmp/result.txt'
FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"'
LINES TERMINATED BY '\n'
FROM test_table;
```

- If you use `INTO DUMPFILE` instead of `INTO OUTFILE`, MySQL writes only one row into the file, without any column or line termination and without performing any escape processing. This is useful if you want to store a `BLOB` value in a file.
- The `INTO` clause can name a list of one or more variables, which can be user-defined variables, or parameters or local variables within a stored function or procedure body. The selected values are assigned to the variables. The number of variables must match the number of columns.

Within a stored routine, the variables can be routine parameters or local variables. See [Section 19.2.7.3, “SELECT ... INTO Statement”](#).

Note

Any file created by `INTO OUTFILE` or `INTO DUMPFILE` is writable by all users on the server host. The reason for this is that the MySQL server cannot create a file that is owned by anyone other than the user under whose account it is running. (You should *never* run `mysqld` as `root` for this and other reasons.) The file thus must be world-writable so that you can manipulate its contents.

- The `SELECT` syntax description at the beginning this section shows the `INTO` clause near the end of the statement. It is also possible to use `INTO OUTFILE` or `INTO DUMPFILE` immediately preceding the `FROM` clause.
- A `PROCEDURE` clause names a procedure that should process the data in the result set. For an example, see [Section 28.4.1, “Procedure Analyse”](#).
- If you use `FOR UPDATE` with a storage engine that uses page or row locks, rows examined by the query are write-locked until the end of the current transaction. Using `LOCK IN SHARE MODE` sets a shared lock that allows other transactions to read the examined rows but not to update or delete them. See [Section 13.5.10.5, “SELECT ... FOR UPDATE and SELECT ... LOCK IN SHARE MODE Locking Reads”](#).

Following the `SELECT` keyword, you can use a number of options that affect the operation of the statement.

The `ALL`, `DISTINCT`, and `DISTINCTROW` options specify whether duplicate rows should be returned. If none of these options are given, the default is `ALL` (all matching rows are returned). `DISTINCT` and `DISTINCTROW` are synonyms and specify removal of duplic-

ate rows from the result set.

HIGH_PRIORITY, **STRAIGHT_JOIN**, and options beginning with **SQL_** are MySQL extensions to standard SQL.

- **HIGH_PRIORITY** gives the **SELECT** higher priority than a statement that updates a table. You should use this only for queries that are very fast and must be done at once. A **SELECT HIGH_PRIORITY** query that is issued while the table is locked for reading runs even if there is an update statement waiting for the table to be free. This affects only storage engines that use only table-level locking (**MyISAM**, **MEMORY**, **MERGE**).

HIGH_PRIORITY cannot be used with **SELECT** statements that are part of a **UNION**.

- **STRAIGHT_JOIN** forces the optimizer to join the tables in the order in which they are listed in the **FROM** clause. You can use this to speed up a query if the optimizer joins the tables in non-optimal order. See [Section 6.2.1, “Optimizing Queries with EXPLAIN”](#). **STRAIGHT_JOIN** also can be used in the *table_references* list. See [Section 12.2.7.1, “JOIN Syntax”](#).
- **SQL_BIG_RESULT** can be used with **GROUP BY** or **DISTINCT** to tell the optimizer that the result set has many rows. In this case, MySQL directly uses disk-based temporary tables if needed, and prefers sorting to using a temporary table with a key on the **GROUP BY** elements.
- **SQL_BUFFER_RESULT** forces the result to be put into a temporary table. This helps MySQL free the table locks early and helps in cases where it takes a long time to send the result set to the client.
- **SQL_SMALL_RESULT** can be used with **GROUP BY** or **DISTINCT** to tell the optimizer that the result set is small. In this case, MySQL uses fast temporary tables to store the resulting table instead of using sorting. This should not normally be needed.
- **SQL_CALC_FOUND_ROWS** tells MySQL to calculate how many rows there would be in the result set, disregarding any **LIMIT** clause. The number of rows can then be retrieved with **SELECT FOUND_ROWS()**. See [Section 11.11.3, “Information Functions”](#).
- **SQL_CACHE** tells MySQL to store the query result in the query cache if you are using a *query_cache_type* value of 2 or **DEMAND**. For a query that uses **UNION** or subqueries, this option effects any **SELECT** in the query. See [Section 6.5.4, “The MySQL Query Cache”](#).
- **SQL_NO_CACHE** tells MySQL not to store the query result in the query cache. See [Section 6.5.4, “The MySQL Query Cache”](#). For a query that uses **UNION** or subqueries, this option effects any **SELECT** in the query.

12.2.7.1. JOIN Syntax

MySQL supports the following **JOIN** syntaxes for the *table_references* part of **SELECT** statements and multiple-table **DELETE** and **UPDATE** statements:

```

table_references:
    table_reference [, table_reference] ...

table_reference:
    table_factor
  | join_table

table_factor:
    tbl_name [[AS] alias] [index_hint_list]
  | ( table_references )
  | { OJ table_reference LEFT OUTER JOIN table_reference
      ON conditional_expr }

join_table:
    table_reference [INNER | CROSS] JOIN table_factor [join_condition]
  | table_reference STRAIGHT_JOIN table_factor
  | table_reference STRAIGHT_JOIN table_factor ON condition
  | table_reference LEFT [OUTER] JOIN table_reference join_condition
  | table_reference NATURAL [LEFT [OUTER]] JOIN table_factor
  | table_reference RIGHT [OUTER] JOIN table_reference join_condition
  | table_reference NATURAL [RIGHT [OUTER]] JOIN table_factor

join_condition:
    ON conditional_expr
  | USING (column_list)

index_hint_list:
    index_hint [, index_hint] ...

index_hint:
    USE {INDEX|KEY}
      [{FOR {JOIN|ORDER BY|GROUP BY}}] ([index_list])
  | IGNORE {INDEX|KEY}
      [{FOR {JOIN|ORDER BY|GROUP BY}}] (index_list)

```

```
| FORCE {INDEX|KEY}
  [{FOR {JOIN|ORDER BY|GROUP BY}}] (index_list)
index_list:
  index_name [, index_name] ...
```

A table reference is also known as a join expression.

The syntax of *table_factor* is extended in comparison with the SQL Standard. The latter accepts only *table_reference*, not a list of them inside a pair of parentheses.

This is a conservative extension if we consider each comma in a list of *table_reference* items as equivalent to an inner join. For example:

```
SELECT * FROM t1 LEFT JOIN (t2, t3, t4)
                      ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

is equivalent to:

```
SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4)
                      ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

In MySQL, **CROSS JOIN** is a syntactic equivalent to **INNER JOIN** (they can replace each other). In standard SQL, they are not equivalent. **INNER JOIN** is used with an **ON** clause, **CROSS JOIN** is used otherwise.

In general, parentheses can be ignored in join expressions containing only inner join operations. MySQL also supports nested joins (see [Section 6.2.9, “Nested Join Optimization”](#)).

Index hints can be specified to affect how the MySQL optimizer makes use of indexes. For more information, see [Section 12.2.7.2, “Index Hint Syntax”](#).

The following list describes general factors to take into account when writing joins.

- A table reference can be aliased using *tbl_name AS alias_name* or *tbl_name alias_name*:

```
SELECT t1.name, t2.salary
  FROM employee AS t1 INNER JOIN info AS t2 ON t1.name = t2.name;

SELECT t1.name, t2.salary
  FROM employee t1 INNER JOIN info t2 ON t1.name = t2.name;
```

- INNER JOIN** and **,** (comma) are semantically equivalent in the absence of a join condition: both produce a Cartesian product between the specified tables (that is, each and every row in the first table is joined to each and every row in the second table).

However, the precedence of the comma operator is less than of **INNER JOIN**, **CROSS JOIN**, **LEFT JOIN**, and so on. If you mix comma joins with the other join types when there is a join condition, an error of the form **Unknown column 'col_name' in 'on clause'** may occur. Information about dealing with this problem is given later in this section.

- The **ON** conditional is any conditional expression of the form that can be used in a **WHERE** clause. Generally, you should use the **ON** clause for conditions that specify how to join tables, and the **WHERE** clause to restrict which rows you want in the result set.
- If there is no matching row for the right table in the **ON** or **USING** part in a **LEFT JOIN**, a row with all columns set to **NULL** is used for the right table. You can use this fact to find rows in a table that have no counterpart in another table:

```
SELECT left_tbl.*
  FROM left_tbl LEFT JOIN right_tbl ON left_tbl.id = right_tbl.id
 WHERE right_tbl.id IS NULL;
```

This example finds all rows in *left_tbl* with an *id* value that is not present in *right_tbl* (that is, all rows in *left_tbl* with no corresponding row in *right_tbl*). This assumes that *right_tbl.id* is declared **NOT NULL**. See [Section 6.2.8, “LEFT JOIN and RIGHT JOIN Optimization”](#).

- The **USING(column_list)** clause names a list of columns that must exist in both tables. If tables *a* and *b* both contain columns *c1*, *c2*, and *c3*, the following join compares corresponding columns from the two tables:

```
a LEFT JOIN b USING (c1,c2,c3)
```

- The **NATURAL [LEFT] JOIN** of two tables is defined to be semantically equivalent to an **INNER JOIN** or a **LEFT JOIN** with a **USING** clause that names all columns that exist in both tables.
- **RIGHT JOIN** works analogously to **LEFT JOIN**. To keep code portable across databases, it is recommended that you use **LEFT JOIN** instead of **RIGHT JOIN**.
- The **{ OJ ... LEFT OUTER JOIN ... }** syntax shown in the join syntax description exists only for compatibility with ODBC. The curly braces in the syntax should be written literally; they are not metasyntax as used elsewhere in syntax descriptions.
- **STRAIGHT_JOIN** is similar to **JOIN**, except that the left table is always read before the right table. This can be used for those (few) cases for which the join optimizer puts the tables in the wrong order.

Some join examples:

```
SELECT * FROM table1, table2;
SELECT * FROM table1 INNER JOIN table2 ON table1.id=table2.id;
SELECT * FROM table1 LEFT JOIN table2 ON table1.id=table2.id;
SELECT * FROM table1 LEFT JOIN table2 USING (id);
SELECT * FROM table1 LEFT JOIN table2 ON table1.id=table2.id
LEFT JOIN table3 ON table2.id=table3.id;
```

Join Processing Changes in MySQL 5.0.12

Note

Natural joins and joins with **USING**, including outer join variants, are processed according to the SQL:2003 standard. The goal was to align the syntax and semantics of MySQL with respect to **NATURAL JOIN** and **JOIN ... USING** according to SQL:2003. However, these changes in join processing can result in different output columns for some joins. Also, some queries that appeared to work correctly in older versions (prior to 5.0.12) must be rewritten to comply with the standard.

These changes have five main aspects:

- The way that MySQL determines the result columns of **NATURAL** or **USING** join operations (and thus the result of the entire **FROM** clause).
- Expansion of **SELECT *** and **SELECT tbl_name.*** into a list of selected columns.
- Resolution of column names in **NATURAL** or **USING** joins.
- Transformation of **NATURAL** or **USING** joins into **JOIN ... ON**.
- Resolution of column names in the **ON** condition of a **JOIN ... ON**.

The following list provides more detail about several effects of current join processing versus join processing in older versions. The term “previously” means “prior to MySQL 5.0.12.”

- The columns of a **NATURAL** join or a **USING** join may be different from previously. Specifically, redundant output columns no longer appear, and the order of columns for **SELECT *** expansion may be different from before.

Consider this set of statements:

```
CREATE TABLE t1 (i INT, j INT);
CREATE TABLE t2 (k INT, j INT);
INSERT INTO t1 VALUES(1,1);
INSERT INTO t2 VALUES(1,1);
SELECT * FROM t1 NATURAL JOIN t2;
SELECT * FROM t1 JOIN t2 USING (j);
```

Previously, the statements produced this output:

i	j	k	j
1	1	1	1
i	j	k	j
1	1	1	1

In the first **SELECT** statement, column **j** appears in both tables and thus becomes a join column, so, according to standard SQL, it should appear only once in the output, not twice. Similarly, in the second **SELECT** statement, column **j** is named in the **USING** clause and should appear only once in the output, not twice. But in both cases, the redundant column is not eliminated. Also, the order of the columns is not correct according to standard SQL.

Now the statements produce this output:

j	i	k
1	1	1
j	i	k
1	1	1

The redundant column is eliminated and the column order is correct according to standard SQL:

- First, coalesced common columns of the two joined tables, in the order in which they occur in the first table
- Second, columns unique to the first table, in order in which they occur in that table
- Third, columns unique to the second table, in order in which they occur in that table

The single result column that replaces two common columns is defined via the coalesce operation. That is, for two **t1.a** and **t2.a** the resulting single join column **a** is defined as **a = COALESCE(t1.a, t2.a)**, where:

```
COALESCE(x, y) = (CASE WHEN V1 IS NOT NULL THEN V1 ELSE V2 END)
```

If the join operation is any other join, the result columns of the join consists of the concatenation of all columns of the joined tables. This is the same as previously.

A consequence of the definition of coalesced columns is that, for outer joins, the coalesced column contains the value of the non-**NULL** column if one of the two columns is always **NULL**. If neither or both columns are **NULL**, both common columns have the same value, so it doesn't matter which one is chosen as the value of the coalesced column. A simple way to interpret this is to consider that a coalesced column of an outer join is represented by the common column of the inner table of a **JOIN**. Suppose that the tables **t1(a,b)** and **t2(a,c)** have the following contents:

t1	t2
1 x	2 z
2 y	3 w

Then:

```
mysql> SELECT * FROM t1 NATURAL LEFT JOIN t2;
```

a	b	c
1	x	NULL
2	y	z

Here column **a** contains the values of **t1.a**.

```
mysql> SELECT * FROM t1 NATURAL RIGHT JOIN t2;
```

a	c	b

2	z	y
3	w	NULL

Here column `a` contains the values of `t2.a`.

Compare these results to the otherwise equivalent queries with `JOIN ... ON`:

```
mysql> SELECT * FROM t1 LEFT JOIN t2 ON (t1.a = t2.a);
```

a	b	a	c
1	x	NULL	NULL
2	y	2	z

```
mysql> SELECT * FROM t1 RIGHT JOIN t2 ON (t1.a = t2.a);
```

a	b	a	c
2	y	2	z
NULL	NULL	3	w

- Previously, a `USING` clause could be rewritten as an `ON` clause that compares corresponding columns. For example, the following two clauses were semantically identical:

```
a LEFT JOIN b USING (c1,c2,c3)
a LEFT JOIN b ON a.c1=b.c1 AND a.c2=b.c2 AND a.c3=b.c3
```

Now the two clauses no longer are quite the same:

- With respect to determining which rows satisfy the join condition, both joins remain semantically identical.
- With respect to determining which columns to display for `SELECT *` expansion, the two joins are not semantically identical. The `USING` join selects the coalesced value of corresponding columns, whereas the `ON` join selects all columns from all tables. For the preceding `USING` join, `SELECT *` selects these values:

```
COALESCE(a.c1,b.c1), COALESCE(a.c2,b.c2), COALESCE(a.c3,b.c3)
```

For the `ON` join, `SELECT *` selects these values:

```
a.c1, a.c2, a.c3, b.c1, b.c2, b.c3
```

With an inner join, `COALESCE(a.c1,b.c1)` is the same as either `a.c1` or `b.c1` because both columns will have the same value. With an outer join (such as `LEFT JOIN`), one of the two columns can be `NULL`. That column will be omitted from the result.

- The evaluation of multi-way natural joins differs in a very important way that affects the result of `NATURAL` or `USING` joins and that can require query rewriting. Suppose that you have three tables `t1(a,b)`, `t2(c,b)`, and `t3(a,c)` that each have one row: `t1(1,2)`, `t2(10,2)`, and `t3(7,10)`. Suppose also that you have this `NATURAL JOIN` on the three tables:

```
SELECT ... FROM t1 NATURAL JOIN t2 NATURAL JOIN t3;
```

Previously, the left operand of the second join was considered to be `t2`, whereas it should be the nested join (`t1 NATURAL JOIN t2`). As a result, the columns of `t3` are checked for common columns only in `t2`, and, if `t3` has common columns with `t1`, these columns are not used as equi-join columns. Thus, previously, the preceding query was transformed to the following equi-join:

```
SELECT ... FROM t1, t2, t3
WHERE t1.b = t2.b AND t2.c = t3.c;
```

That join is missing one more equi-join predicate (`t1.a = t3.a`). As a result, it produces one row, not the empty result that it should. The correct equivalent query is this:

```
SELECT ... FROM t1, t2, t3
WHERE t1.b = t2.b AND t2.c = t3.c AND t1.a = t3.a;
```

If you require the same query result in current versions of MySQL as in older versions, rewrite the natural join as the first equi-join.

- Previously, the comma operator (,) and **JOIN** both had the same precedence, so the join expression `t1, t2 JOIN t3` was interpreted as `((t1, t2) JOIN t3)`. Now **JOIN** has higher precedence, so the expression is interpreted as `(t1, (t2 JOIN t3))`. This change affects statements that use an **ON** clause, because that clause can refer only to columns in the operands of the join, and the change in precedence changes interpretation of what those operands are.

Example:

```
CREATE TABLE t1 (i1 INT, j1 INT);
CREATE TABLE t2 (i2 INT, j2 INT);
CREATE TABLE t3 (i3 INT, j3 INT);
INSERT INTO t1 VALUES(1,1);
INSERT INTO t2 VALUES(1,1);
INSERT INTO t3 VALUES(1,1);
SELECT * FROM t1, t2 JOIN t3 ON (t1.i1 = t3.i3);
```

Previously, the **SELECT** was legal due to the implicit grouping of `t1, t2` as `(t1, t2)`. Now the **JOIN** takes precedence, so the operands for the **ON** clause are `t2` and `t3`. Because `t1.i1` is not a column in either of the operands, the result is an **Unknown column 't1.i1' in 'on clause'** error. To allow the join to be processed, group the first two tables explicitly with parentheses so that the operands for the **ON** clause are `(t1, t2)` and `t3`:

```
SELECT * FROM (t1, t2) JOIN t3 ON (t1.i1 = t3.i3);
```

Alternatively, avoid the use of the comma operator and use **JOIN** instead:

```
SELECT * FROM t1 JOIN t2 JOIN t3 ON (t1.i1 = t3.i3);
```

This change also applies to statements that mix the comma operator with **INNER JOIN**, **CROSS JOIN**, **LEFT JOIN**, and **RIGHT JOIN**, all of which now have higher precedence than the comma operator.

- Previously, the **ON** clause could refer to columns in tables named to its right. Now an **ON** clause can refer only to its operands.

Example:

```
CREATE TABLE t1 (i1 INT);
CREATE TABLE t2 (i2 INT);
CREATE TABLE t3 (i3 INT);
SELECT * FROM t1 JOIN t2 ON (i1 = i3) JOIN t3;
```

Previously, the **SELECT** statement was legal. Now the statement fails with an **Unknown column 'i3' in 'on clause'** error because `i3` is a column in `t3`, which is not an operand of the **ON** clause. The statement should be rewritten as follows:

```
SELECT * FROM t1 JOIN t2 JOIN t3 ON (i1 = i3);
```

- Resolution of column names in **NATURAL** or **USING** joins is different than previously. For column names that are outside the **FROM** clause, MySQL now handles a superset of the queries compared to previously. That is, in cases when MySQL formerly issued an error that some column is ambiguous, the query now is handled correctly. This is due to the fact that MySQL now treats the common columns of **NATURAL** or **USING** joins as a single column, so when a query refers to such columns, the query compiler does not consider them as ambiguous.

Example:

```
SELECT * FROM t1 NATURAL JOIN t2 WHERE b > 1;
```

Previously, this query would produce an error **ERROR 1052 (23000): Column 'b' in where clause is ambiguous**. Now the query produces the correct result:

b	c	y
4	2	3

One extension of MySQL compared to the SQL:2003 standard is that MySQL allows you to qualify the common (coalesced)

columns of **NATURAL** or **USING** joins (just as previously), while the standard disallows that.

12.2.7.2. Index Hint Syntax

You can provide hints to give the optimizer information about how to choose indexes during query processing. [Section 12.2.7.1, “JOIN Syntax”](#), describes the general syntax for specifying tables in a **SELECT** statement. The syntax for an individual table, including that for index hints, looks like this:

```
tbl_name [[AS] alias] [index_hint_list]
index_hint_list:
    index_hint [, index_hint] ...
index_hint:
    USE {INDEX|KEY}
        [{FOR {JOIN|ORDER BY|GROUP BY}}] ([index_list])
    | IGNORE {INDEX|KEY}
        [{FOR {JOIN|ORDER BY|GROUP BY}}] (index_list)
    | FORCE {INDEX|KEY}
        [{FOR {JOIN|ORDER BY|GROUP BY}}] (index_list)
index_list:
    index_name [, index_name] ...
```

By specifying **USE INDEX (index_list)**, you can tell MySQL to use only one of the named indexes to find rows in the table. The alternative syntax **IGNORE INDEX (index_list)** can be used to tell MySQL to not use some particular index or indexes. These hints are useful if **EXPLAIN** shows that MySQL is using the wrong index from the list of possible indexes.

You can also use **FORCE INDEX**, which acts like **USE INDEX (index_list)** but with the addition that a table scan is assumed to be very expensive. In other words, a table scan is used only if there is no way to use one of the given indexes to find rows in the table.

USE KEY, **IGNORE KEY**, and **FORCE KEY** are synonyms for **USE INDEX**, **IGNORE INDEX**, and **FORCE INDEX**.

Each hint requires the names of *indexes*, not the names of columns. The name of a **PRIMARY KEY** is **PRIMARY**. To see the index names for a table, use **SHOW INDEX**.

Index hints do not work for **FULLTEXT** indexes.

Prior to MySQL 5.1.17, **USE INDEX**, **IGNORE INDEX**, and **FORCE INDEX** affect only which indexes are used when MySQL decides how to find rows in the table and how to process joins. They do not affect whether an index is used when resolving an **ORDER BY** or **GROUP BY** clause.

Examples:

```
SELECT * FROM table1 USE INDEX (col1_index,col2_index)
WHERE col1=1 AND col2=2 AND col3=3;

SELECT * FROM table1 IGNORE INDEX (col3_index)
WHERE col1=1 AND col2=2 AND col3=3;
```

As of MySQL 5.1.17, the syntax for index hints is extended in the following ways:

- It is syntactically valid to specify an empty *index_list* for **USE INDEX**, which means “use no indexes.” Specifying an empty *index_list* for **FORCE INDEX** or **IGNORE INDEX** is a syntax error.
- You can specify the scope of a index hint by adding a **FOR** clause to the hint. This provides more fine-grained control over the optimizer's selection of an execution plan for various phases of query processing. To affect only the indexes used when MySQL decides how to find rows in the table and how to process joins, use **FOR JOIN**. To influence index usage for sorting or grouping rows, use **FOR ORDER BY** or **FOR GROUP BY**. (However, if there is a covering index for the table and it is used to access the table, the optimizer will ignore **IGNORE INDEX FOR {ORDER BY|GROUP BY}** hints that disable that index.)
- You can specify multiple index hints:

```
SELECT * FROM t1 USE INDEX (i1) IGNORE INDEX FOR ORDER BY (i2) ORDER BY a;
```

It is not a error to name the same index in several hints (even within the same hint):

```
SELECT * FROM t1 USE INDEX (i1) USE INDEX (i1,i1);
```

However, it is an error to mix **USE INDEX** and **FORCE INDEX** for the same table:

```
SELECT * FROM t1 USE INDEX FOR JOIN (i1) FORCE INDEX FOR JOIN (i2);
```

The default scope of index hints also is changed as of MySQL 5.1.17. Formerly, index hints applied only to how indexes are used for retrieval of records and not during resolution of **ORDER BY** or **GROUP BY** clauses. As of 5.1.17, if you specify no **FOR** clause for an index hint, the hint by default applies to all parts of the statement. For example, this hint:

```
IGNORE INDEX (i1)
```

is equivalent to this combination of hints:

```
IGNORE INDEX FOR JOIN (i1)
IGNORE INDEX FOR ORDER BY (i1)
IGNORE INDEX FOR GROUP BY (i1)
```

To cause the server to use the older behavior for hint scope when no **FOR** clause is present (so that hints apply only to row retrieval), enable the **old** system variable at server startup. Take care about enabling this variable in a replication setup. With statement-based binary logging, having different modes for the master and slaves might lead to replication errors.

When index hints are processed, they are collected in a single list by type (**USE**, **FORCE**, **IGNORE**) and by scope (**FOR JOIN**, **FOR ORDER BY**, **FOR GROUP BY**). For example:

```
SELECT * FROM t1
  USE INDEX () IGNORE INDEX (i2) USE INDEX (i1) USE INDEX (i2);
```

is equivalent to:

```
SELECT * FROM t1
  USE INDEX (i1,i2) IGNORE INDEX (i2);
```

The index hints then are applied for each scope in the following order:

1. **{USE|FORCE} INDEX** is applied if present. (If not, the optimizer-determined set of indexes is used.)
2. **IGNORE INDEX** is applied over the result of the previous step. For example:

```
SELECT * FROM t1 USE INDEX (i1) IGNORE INDEX (i2) USE INDEX (i2)
```

is equivalent to:

```
SELECT * FROM t1 USE INDEX (i1).
```

12.2.7.3. **UNION** Syntax

```
SELECT ...
UNION [ALL | DISTINCT] SELECT ...
[UNION [ALL | DISTINCT] SELECT ...]
```

UNION is used to combine the result from multiple **SELECT** statements into a single result set.

The column names from the first **SELECT** statement are used as the column names for the results returned. Selected columns listed in corresponding positions of each **SELECT** statement should have the same data type. (For example, the first column selected by the first statement should have the same type as the first column selected by the other statements.)

If the data types of corresponding **SELECT** columns do not match, the types and lengths of the columns in the **UNION** result take into account the values retrieved by all of the **SELECT** statements. For example, consider the following:

```
mysql> SELECT REPEAT('a',1) UNION SELECT REPEAT('b',10);
+-----+
| REPEAT('a',1) |
+-----+
| a              |
| bbbbbbbbbbb   |
+-----+
```

(In some earlier versions of MySQL, only the type and length from the first **SELECT** would have been used and the second row would have been truncated to a length of 1.)

The **SELECT** statements are normal select statements, but with the following restrictions:

- Only the last **SELECT** statement can use **INTO OUTFILE**.
- **HIGH_PRIORITY** cannot be used with **SELECT** statements that are part of a **UNION**. If you specify it for the first **SELECT**, it has no effect. If you specify it for any subsequent **SELECT** statements, a syntax error results.

The default behavior for **UNION** is that duplicate rows are removed from the result. The optional **DISTINCT** keyword has no effect other than the default because it also specifies duplicate-row removal. With the optional **ALL** keyword, duplicate-row removal does not occur and the result includes all matching rows from all the **SELECT** statements.

You can mix **UNION ALL** and **UNION DISTINCT** in the same query. Mixed **UNION** types are treated such that a **DISTINCT** union overrides any **ALL** union to its left. A **DISTINCT** union can be produced explicitly by using **UNION DISTINCT** or implicitly by using **UNION** with no following **DISTINCT** or **ALL** keyword.

To use an **ORDER BY** or **LIMIT** clause to sort or limit the entire **UNION** result, parenthesize the individual **SELECT** statements and place the **ORDER BY** or **LIMIT** after the last one. The following example uses both clauses:

```
(SELECT a FROM t1 WHERE a=10 AND B=1)
UNION
(SELECT a FROM t2 WHERE a=11 AND B=2)
ORDER BY a LIMIT 10;
```

This kind of **ORDER BY** cannot use column references that include a table name (that is, names in *tbl_name.col_name* format). Instead, provide a column alias in the first **SELECT** statement and refer to the alias in the **ORDER BY**. (Alternatively, refer to the column in the **ORDER BY** using its column position. However, use of column positions is deprecated.)

Also, if a column to be sorted is aliased, the **ORDER BY** clause *must* refer to the alias, not the column name. The first of the following statements will work, but the second will fail with an **Unknown column 'a' in 'order clause'** error:

```
(SELECT a AS b FROM t) UNION (SELECT ... ) ORDER BY b;
(SELECT a AS b FROM t) UNION (SELECT ... ) ORDER BY a;
```

To apply **ORDER BY** or **LIMIT** to an individual **SELECT**, place the clause inside the parentheses that enclose the **SELECT**:

```
(SELECT a FROM t1 WHERE a=10 AND B=1 ORDER BY a LIMIT 10)
UNION
(SELECT a FROM t2 WHERE a=11 AND B=2 ORDER BY a LIMIT 10);
```

Use of **ORDER BY** for individual **SELECT** statements implies nothing about the order in which the rows appear in the final result because **UNION** by default produces an unordered set of rows. If **ORDER BY** appears with **LIMIT**, it is used to determine the subset of the selected rows to retrieve for the **SELECT**, but does not necessarily affect the order of those rows in the final **UNION** result. If **ORDER BY** appears without **LIMIT** in a **SELECT**, it is optimized away because it will have no effect anyway.

To cause rows in a **UNION** result to consist of the sets of rows retrieved by each **SELECT** one after the other, select an additional column in each **SELECT** to use as a sort column and add an **ORDER BY** following the last **SELECT**:

```
(SELECT 1 AS sort_col, col1a, col1b, ... FROM t1)
UNION
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col;
```

To additionally maintain sort order within individual **SELECT** results, add a secondary column to the **ORDER BY** clause:

```
(SELECT 1 AS sort_col, col1a, col1b, ... FROM t1)
UNION
```

```
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col, col1a;
```

12.2.8. Subquery Syntax

A subquery is a [SELECT](#) statement within another statement.

Starting with MySQL 4.1, all subquery forms and operations that the SQL standard requires are supported, as well as a few features that are MySQL-specific.

Here is an example of a subquery:

```
SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
```

In this example, [SELECT * FROM t1 ...](#) is the *outer query* (or *outer statement*), and [\(SELECT column1 FROM t2\)](#) is the *subquery*. We say that the subquery is *nested* within the outer query, and in fact it is possible to nest subqueries within other subqueries, to a considerable depth. A subquery must always appear within parentheses.

The main advantages of subqueries are:

- They allow queries that are *structured* so that it is possible to isolate each part of a statement.
- They provide alternative ways to perform operations that would otherwise require complex joins and unions.
- They are, in many people's opinion, more readable than complex joins or unions. Indeed, it was the innovation of subqueries that gave people the original idea of calling the early SQL “Structured Query Language.”

Here is an example statement that shows the major points about subquery syntax as specified by the SQL standard and supported in MySQL:

```
DELETE FROM t1
WHERE s11 > ANY
  (SELECT COUNT(*) /* no hint */ FROM t2
  WHERE NOT EXISTS
    (SELECT * FROM t3
     WHERE ROW(5*t2.s1,77)=
      (SELECT 50,11*s1 FROM t4 UNION SELECT 50,77 FROM
       (SELECT * FROM t5) AS t5)));
```

A subquery can return a scalar (a single value), a single row, a single column, or a table (one or more rows of one or more columns). These are called scalar, column, row, and table subqueries. Subqueries that return a particular kind of result often can be used only in certain contexts, as described in the following sections.

There are few restrictions on the type of statements in which subqueries can be used. A subquery can contain any of the keywords or clauses that an ordinary [SELECT](#) can contain: [DISTINCT](#), [GROUP BY](#), [ORDER BY](#), [LIMIT](#), joins, index hints, [UNION](#) constructs, comments, functions, and so on.

One restriction is that a subquery's outer statement must be one of: [SELECT](#), [INSERT](#), [UPDATE](#), [DELETE](#), [SET](#), or [DO](#). Another restriction is that currently you cannot modify a table and select from the same table in a subquery. This applies to statements such as [DELETE](#), [INSERT](#), [REPLACE](#), [UPDATE](#), and (because subqueries can be used in the [SET](#) clause) [LOAD DATA INFILE](#).

A more comprehensive discussion of restrictions on subquery use, including performance issues for certain forms of subquery syntax, is given in [Section D.3, “Restrictions on Subqueries”](#).

12.2.8.1. The Subquery as Scalar Operand

In its simplest form, a subquery is a scalar subquery that returns a single value. A scalar subquery is a simple operand, and you can use it almost anywhere a single column value or literal is legal, and you can expect it to have those characteristics that all operands have: a data type, a length, an indication whether it can be [NULL](#), and so on. For example:

```
CREATE TABLE t1 (s1 INT, s2 CHAR(5) NOT NULL);
INSERT INTO t1 VALUES(100, 'abcde');
SELECT (SELECT s2 FROM t1);
```

The subquery in this [SELECT](#) returns a single value ('abcde') that has a data type of [CHAR](#), a length of 5, a character set and colla-

tion equal to the defaults in effect at **CREATE TABLE** time, and an indication that the value in the column can be **NULL**. In fact, almost all subqueries can be **NULL**. If the table used in the example were empty, the value of the subquery would be **NULL**.

There are a few contexts in which a scalar subquery cannot be used. If a statement allows only a literal value, you cannot use a subquery. For example, **LIMIT** requires literal integer arguments, and **LOAD DATA INFILE** requires a literal string filename. You cannot use subqueries to supply these values.

When you see examples in the following sections that contain the rather spartan construct **(SELECT column1 FROM t1)**, imagine that your own code contains much more diverse and complex constructions.

Suppose that we make two tables:

```
CREATE TABLE t1 (s1 INT);
INSERT INTO t1 VALUES (1);
CREATE TABLE t2 (s1 INT);
INSERT INTO t2 VALUES (2);
```

Then perform a **SELECT**:

```
SELECT (SELECT s1 FROM t2) FROM t1;
```

The result is **2** because there is a row in **t2** containing a column **s1** that has a value of **2**.

A scalar subquery can be part of an expression, but remember the parentheses, even if the subquery is an operand that provides an argument for a function. For example:

```
SELECT UPPER((SELECT s1 FROM t1)) FROM t2;
```

12.2.8.2. Comparisons Using Subqueries

The most common use of a subquery is in the form:

```
non_subquery_operand comparison_operator (subquery)
```

Where *comparison_operator* is one of these operators:

```
= > < >= <= <>
```

For example:

```
... 'a' = (SELECT column1 FROM t1)
```

At one time the only legal place for a subquery was on the right side of a comparison, and you might still find some old DBMSs that insist on this.

Here is an example of a common-form subquery comparison that you cannot do with a join. It finds all the values in table **t1** that are equal to a maximum value in table **t2**:

```
SELECT column1 FROM t1
WHERE column1 = (SELECT MAX(column2) FROM t2);
```

Here is another example, which again is impossible with a join because it involves aggregating for one of the tables. It finds all rows in table **t1** containing a value that occurs twice in a given column:

```
SELECT * FROM t1 AS t
WHERE 2 = (SELECT COUNT(*) FROM t1 WHERE t1.id = t.id);
```

For a comparison performed with one of these operators, the subquery must return a scalar, with the exception that **=** can be used with row subqueries. See [Section 12.2.8.5, “Row Subqueries”](#).

12.2.8.3. Subqueries with **ANY**, **IN**, and **SOME**

Syntax:

```
operand comparison_operator ANY (subquery)
```

```
operand IN (subquery)
operand comparison_operator SOME (subquery)
```

The **ANY** keyword, which must follow a comparison operator, means “return **TRUE** if the comparison is **TRUE** for **ANY** of the values in the column that the subquery returns.” For example:

```
SELECT s1 FROM t1 WHERE s1 > ANY (SELECT s1 FROM t2);
```

Suppose that there is a row in table **t1** containing (**10**). The expression is **TRUE** if table **t2** contains (**21, 14, 7**) because there is a value **7** in **t2** that is less than **10**. The expression is **FALSE** if table **t2** contains (**20, 10**), or if table **t2** is empty. The expression is *unknown* if table **t2** contains (**NULL, NULL, NULL**).

When used with a subquery, the word **IN** is an alias for **= ANY**. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 = ANY (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 IN (SELECT s1 FROM t2);
```

IN and **= ANY** are not synonyms when used with an expression list. **IN** can take an expression list, but **= ANY** cannot. See [Section 11.2.3, “Comparison Functions and Operators”](#).

NOT IN is not an alias for **<> ANY**, but for **<> ALL**. See [Section 12.2.8.4, “Subqueries with ALL”](#).

The word **SOME** is an alias for **ANY**. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 <> ANY (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 <> SOME (SELECT s1 FROM t2);
```

Use of the word **SOME** is rare, but this example shows why it might be useful. To most people's ears, the English phrase “a is not equal to any b” means “there is no b which is equal to a,” but that is not what is meant by the SQL syntax. The syntax means “there is some b to which a is not equal.” Using **<> SOME** instead helps ensure that everyone understands the true meaning of the query.

12.2.8.4. Subqueries with ALL

Syntax:

```
operand comparison_operator ALL (subquery)
```

The word **ALL**, which must follow a comparison operator, means “return **TRUE** if the comparison is **TRUE** for **ALL** of the values in the column that the subquery returns.” For example:

```
SELECT s1 FROM t1 WHERE s1 > ALL (SELECT s1 FROM t2);
```

Suppose that there is a row in table **t1** containing (**10**). The expression is **TRUE** if table **t2** contains (**-5, 0, +5**) because **10** is greater than all three values in **t2**. The expression is **FALSE** if table **t2** contains (**12, 6, NULL, -100**) because there is a single value **12** in table **t2** that is greater than **10**. The expression is *unknown* (that is, **NULL**) if table **t2** contains (**0, NULL, 1**).

Finally, if table **t2** is empty, the result is **TRUE**. So, the following statement is **TRUE** when table **t2** is empty:

```
SELECT * FROM t1 WHERE 1 > ALL (SELECT s1 FROM t2);
```

But this statement is **NULL** when table **t2** is empty:

```
SELECT * FROM t1 WHERE 1 > (SELECT s1 FROM t2);
```

In addition, the following statement is **NULL** when table **t2** is empty:

```
SELECT * FROM t1 WHERE 1 > ALL (SELECT MAX(s1) FROM t2);
```

In general, *tables containing NULL values* and *empty tables* are “edge cases.” When writing subquery code, always consider whether you have taken those two possibilities into account.

NOT IN is an alias for **<> ALL**. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 <> ALL (SELECT s1 FROM t2);
```

```
SELECT s1 FROM t1 WHERE s1 NOT IN (SELECT s1 FROM t2);
```

12.2.8.5. Row Subqueries

The discussion to this point has been of scalar or column subqueries; that is, subqueries that return a single value or a column of values. A *row subquery* is a subquery variant that returns a single row and can thus return more than one column value. Here are two examples:

```
SELECT * FROM t1 WHERE (1,2) = (SELECT column1, column2 FROM t2);
SELECT * FROM t1 WHERE ROW(1,2) = (SELECT column1, column2 FROM t2);
```

The queries here are both **TRUE** if table **t2** has a row where **column1 = 1** and **column2 = 2**.

The expressions **(1, 2)** and **ROW(1, 2)** are sometimes called *row constructors*. The two are equivalent. They are legal in other contexts as well. For example, the following two statements are semantically equivalent (although the first one cannot be optimized until MySQL 5.1.12):

```
SELECT * FROM t1 WHERE (column1,column2) = (1,1);
SELECT * FROM t1 WHERE column1 = 1 AND column2 = 1;
```

The normal use of row constructors is for comparisons with subqueries that return two or more columns. For example, the following query answers the request, “find all rows in table **t1** that also exist in table **t2**”:

```
SELECT column1,column2,column3
FROM t1
WHERE (column1,column2,column3) IN
(SELECT column1,column2,column3 FROM t2);
```

12.2.8.6. EXISTS and NOT EXISTS

If a subquery returns any rows at all, **EXISTS subquery** is **TRUE**, and **NOT EXISTS subquery** is **FALSE**. For example:

```
SELECT column1 FROM t1 WHERE EXISTS (SELECT * FROM t2);
```

Traditionally, an **EXISTS** subquery starts with **SELECT ***, but it could begin with **SELECT 5** or **SELECT column1** or anything at all. MySQL ignores the **SELECT** list in such a subquery, so it makes no difference.

For the preceding example, if **t2** contains any rows, even rows with nothing but **NULL** values, the **EXISTS** condition is **TRUE**. This is actually an unlikely example because a **[NOT] EXISTS** subquery almost always contains correlations. Here are some more realistic examples:

- What kind of store is present in one or more cities?

```
SELECT DISTINCT store_type FROM stores
WHERE EXISTS (SELECT * FROM cities_stores
              WHERE cities_stores.store_type = stores.store_type);
```

- What kind of store is present in no cities?

```
SELECT DISTINCT store_type FROM stores
WHERE NOT EXISTS (SELECT * FROM cities_stores
                  WHERE cities_stores.store_type = stores.store_type);
```

- What kind of store is present in all cities?

```
SELECT DISTINCT store_type FROM stores s1
WHERE NOT EXISTS (
  SELECT * FROM cities WHERE NOT EXISTS (
    SELECT * FROM cities_stores
    WHERE cities_stores.city = cities.city
    AND cities_stores.store_type = stores.store_type));
```

The last example is a double-nested **NOT EXISTS** query. That is, it has a **NOT EXISTS** clause within a **NOT EXISTS** clause. Formally, it answers the question “does a city exist with a store that is not in **Stores**”? But it is easier to say that a nested **NOT EXISTS**

answers the question “is x **TRUE** for all y ?”

12.2.8.7. Correlated Subqueries

A *correlated subquery* is a subquery that contains a reference to a table that also appears in the outer query. For example:

```
SELECT * FROM t1 WHERE column1 = ANY
(SELECT column1 FROM t2 WHERE t2.column2 = t1.column2);
```

Notice that the subquery contains a reference to a column of **t1**, even though the subquery's **FROM** clause does not mention a table **t1**. So, MySQL looks outside the subquery, and finds **t1** in the outer query.

Suppose that table **t1** contains a row where **column1** = 5 and **column2** = 6; meanwhile, table **t2** contains a row where **column1** = 5 and **column2** = 7. The simple expression **... WHERE column1 = ANY (SELECT column1 FROM t2)** would be **TRUE**, but in this example, the **WHERE** clause within the subquery is **FALSE** (because (5, 6) is not equal to (5, 7)), so the subquery as a whole is **FALSE**.

Scoping rule: MySQL evaluates from inside to outside. For example:

```
SELECT column1 FROM t1 AS x
WHERE x.column1 = (SELECT column1 FROM t2 AS x
WHERE x.column1 = (SELECT column1 FROM t3
WHERE x.column2 = t3.column1));
```

In this statement, **x.column2** must be a column in table **t2** because **SELECT column1 FROM t2 AS x ...** renames **t2**. It is not a column in table **t1** because **SELECT column1 FROM t1 ...** is an outer query that is *farther out*.

For subqueries in **HAVING** or **ORDER BY** clauses, MySQL also looks for column names in the outer select list.

For certain cases, a correlated subquery is optimized. For example:

```
val IN (SELECT key_val FROM tbl_name WHERE correlated_condition)
```

Otherwise, they are inefficient and likely to be slow. Rewriting the query as a join might improve performance.

Aggregate functions in correlated subqueries may contain outer references, provided the function contains nothing but outer references, and provided the function is not contained in another function or expression.

12.2.8.8. Subqueries in the **FROM** clause

Subqueries are legal in a **SELECT** statement's **FROM** clause. The actual syntax is:

```
SELECT ... FROM (subquery) [AS] name ...
```

The **[AS] name** clause is mandatory, because every table in a **FROM** clause must have a name. Any columns in the *subquery* select list must have unique names. You can find this syntax described elsewhere in this manual, where the term used is “derived tables.”

For the sake of illustration, assume that you have this table:

```
CREATE TABLE t1 (s1 INT, s2 CHAR(5), s3 FLOAT);
```

Here is how to use a subquery in the **FROM** clause, using the example table:

```
INSERT INTO t1 VALUES (1, '1', 1.0);
INSERT INTO t1 VALUES (2, '2', 2.0);
SELECT sb1, sb2, sb3
FROM (SELECT s1 AS sb1, s2 AS sb2, s3*2 AS sb3 FROM t1) AS sb
WHERE sb1 > 1;
```

Result: 2, '2', 4.0.

Here is another example: Suppose that you want to know the average of a set of sums for a grouped table. This does not work:

```
SELECT AVG(SUM(column1)) FROM t1 GROUP BY column1;
```

However, this query provides the desired information:

```
SELECT AVG(sum_column1)
FROM (SELECT SUM(column1) AS sum_column1
FROM t1 GROUP BY column1) AS t1;
```

Notice that the column name used within the subquery (`sum_column1`) is recognized in the outer query.

Subqueries in the `FROM` clause can return a scalar, column, row, or table. Subqueries in the `FROM` clause cannot be correlated subqueries, unless used within the `ON` clause of a `JOIN` operation.

Subqueries in the `FROM` clause are executed even for the `EXPLAIN` statement (that is, derived temporary tables are built). This occurs because upper-level queries need information about all tables during the optimization phase, and the table represented by a subquery in the `FROM` clause is unavailable unless the subquery is executed.

12.2.8.9. Subquery Errors

There are some errors that apply only to subqueries. This section describes them.

- Unsupported subquery syntax:

```
ERROR 1235 (ER_NOT_SUPPORTED_YET)
SQLSTATE = 42000
Message = "This version of MySQL does not yet support
'LIMIT & IN/ALL/ANY/SOME subquery'"
```

This means that statements of the following form do not work yet:

```
SELECT * FROM t1 WHERE s1 IN (SELECT s2 FROM t2 ORDER BY s1 LIMIT 1)
```

- Incorrect number of columns from subquery:

```
ERROR 1241 (ER_OPERAND_COL)
SQLSTATE = 21000
Message = "Operand should contain 1 column(s)"
```

This error occurs in cases like this:

```
SELECT (SELECT column1, column2 FROM t2) FROM t1;
```

You may use a subquery that returns multiple columns, if the purpose is comparison. In other contexts, the subquery must be a scalar operand. See [Section 12.2.8.5, “Row Subqueries”](#).

- Incorrect number of rows from subquery:

```
ERROR 1242 (ER_SUBSELECT_NO_1_ROW)
SQLSTATE = 21000
Message = "Subquery returns more than 1 row"
```

This error occurs for statements where the subquery returns more than one row. Consider the following example:

```
SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
```

If `SELECT column1 FROM t2` returns just one row, the previous query will work. If the subquery returns more than one row, error 1242 will occur. In that case, the query should be rewritten as:

```
SELECT * FROM t1 WHERE column1 = ANY (SELECT column1 FROM t2);
```

- Incorrectly used table in subquery:

```
Error 1093 (ER_UPDATE_TABLE_USED)
SQLSTATE = HY000
Message = "You can't specify target table 'x'
for update in FROM clause"
```

This error occurs in cases such as the following:

```
UPDATE t1 SET column2 = (SELECT MAX(column1) FROM t1);
```

You can use a subquery for assignment within an **UPDATE** statement because subqueries are legal in **UPDATE** and **DELETE** statements as well as in **SELECT** statements. However, you cannot use the same table (in this case, table **t1**) for both the subquery's **FROM** clause and the update target.

For transactional storage engines, the failure of a subquery causes the entire statement to fail. For non-transactional storage engines, data modifications made before the error was encountered are preserved.

12.2.8.10. Optimizing Subqueries

Development is ongoing, so no optimization tip is reliable for the long term. The following list provides some interesting tricks that you might want to play with:

- Use subquery clauses that affect the number or order of the rows in the subquery. For example:

```
SELECT * FROM t1 WHERE t1.column1 IN  
(SELECT column1 FROM t2 ORDER BY column1);  
SELECT * FROM t1 WHERE t1.column1 IN  
(SELECT DISTINCT column1 FROM t2);  
SELECT * FROM t1 WHERE EXISTS  
(SELECT * FROM t2 LIMIT 1);
```

- Replace a join with a subquery. For example, try this:

```
SELECT DISTINCT column1 FROM t1 WHERE t1.column1 IN (  
SELECT column1 FROM t2);
```

Instead of this:

```
SELECT DISTINCT t1.column1 FROM t1, t2  
WHERE t1.column1 = t2.column1;
```

- Some subqueries can be transformed to joins for compatibility with older versions of MySQL that do not support subqueries. However, in some cases, converting a subquery to a join may improve performance. See [Section 12.2.8.11, “Rewriting Subqueries as Joins”](#).
- Move clauses from outside to inside the subquery. For example, use this query:

```
SELECT * FROM t1  
WHERE s1 IN (SELECT s1 FROM t1 UNION ALL SELECT s1 FROM t2);
```

Instead of this query:

```
SELECT * FROM t1  
WHERE s1 IN (SELECT s1 FROM t1) OR s1 IN (SELECT s1 FROM t2);
```

For another example, use this query:

```
SELECT (SELECT column1 + 5 FROM t1) FROM t2;
```

Instead of this query:

```
SELECT (SELECT column1 FROM t1) + 5 FROM t2;
```

- Use a row subquery instead of a correlated subquery. For example, use this query:

```
SELECT * FROM t1  
WHERE (column1,column2) IN (SELECT column1,column2 FROM t2);
```

Instead of this query:

```
SELECT * FROM t1
WHERE EXISTS (SELECT * FROM t2 WHERE t2.column1=t1.column1
AND t2.column2=t1.column2);
```

- Use `NOT (a = ANY (...))` rather than `a <> ALL (...)`.
- Use `x = ANY (table containing (1,2))` rather than `x=1 OR x=2`.
- Use `= ANY` rather than `EXISTS`.
- For uncorrelated subqueries that always return one row, `IN` is always slower than `=`. For example, use this query:

```
SELECT * FROM t1 WHERE t1.col_name
= (SELECT a FROM t2 WHERE b = some_const);
```

Instead of this query:

```
SELECT * FROM t1 WHERE t1.col_name
IN (SELECT a FROM t2 WHERE b = some_const);
```

These tricks might cause programs to go faster or slower. Using MySQL facilities like the `BENCHMARK()` function, you can get an idea about what helps in your own situation. See [Section 11.11.3, “Information Functions”](#).

Some optimizations that MySQL itself makes are:

- MySQL executes uncorrelated subqueries only once. Use `EXPLAIN` to make sure that a given subquery really is uncorrelated.
- MySQL rewrites `IN`, `ALL`, `ANY`, and `SOME` subqueries in an attempt to take advantage of the possibility that the select-list columns in the subquery are indexed.
- MySQL replaces subqueries of the following form with an index-lookup function, which `EXPLAIN` describes as a special join type (`unique_subquery` or `index_subquery`):

```
... IN (SELECT indexed_column FROM single_table ...)
```

- MySQL enhances expressions of the following form with an expression involving `MIN()` or `MAX()`, unless `NULL` values or empty sets are involved:

```
value {ALL|ANY|SOME} {> | < | >= | <=} (uncorrelated subquery)
```

For example, this `WHERE` clause:

```
WHERE 5 > ALL (SELECT x FROM t)
```

might be treated by the optimizer like this:

```
WHERE 5 > (SELECT MAX(x) FROM t)
```

See also the MySQL Internals Manual chapter [How MySQL Transforms Subqueries](#).

12.2.8.11. Rewriting Subqueries as Joins

Although MySQL 5.1 supports subqueries (see [Section 12.2.8, “Subquery Syntax”](#)), it is still true that there are sometimes other ways to test membership in a set of values. It is also true that on some occasions, it is not only possible to rewrite a query without a subquery, but it can be more efficient to make use of some of these techniques rather than to use subqueries. One of these is the `IN()` construct:

For example, this query:

```
SELECT * FROM t1 WHERE id IN (SELECT id FROM t2);
```

Can be rewritten as:

```
SELECT DISTINCT t1.* FROM t1, t2 WHERE t1.id=t2.id;
```

The queries:

```
SELECT * FROM t1 WHERE id NOT IN (SELECT id FROM t2);
SELECT * FROM t1 WHERE NOT EXISTS (SELECT id FROM t2 WHERE t1.id=t2.id);
```

Can be rewritten using `IN()`:

```
SELECT table1.* FROM table1 LEFT JOIN table2 ON table1.id=table2.id
WHERE table2.id IS NULL;
```

A `LEFT [OUTER] JOIN` can be faster than an equivalent subquery because the server might be able to optimize it better — a fact that is not specific to MySQL Server alone. Prior to SQL-92, outer joins did not exist, so subqueries were the only way to do certain things. Today, MySQL Server and many other modern database systems offer a wide range of outer join types.

MySQL Server supports multiple-table `DELETE` statements that can be used to efficiently delete rows based on information from one table or even from many tables at the same time. Multiple-table `UPDATE` statements are also supported. See [Section 12.2.1, “DELETE Syntax”](#), and [Section 12.2.10, “UPDATE Syntax”](#).

12.2.9. TRUNCATE Syntax

```
TRUNCATE [TABLE] tbl_name
```

`TRUNCATE TABLE` empties a table completely. Logically, this is equivalent to a `DELETE` statement that deletes all rows, but there are practical differences under some circumstances.

For `InnoDB` tables, `TRUNCATE TABLE` is mapped to `DELETE` if there are foreign key constraints that reference the table; otherwise fast truncation (dropping and re-creating the table) is used. The `AUTO_INCREMENT` counter is reset by `TRUNCATE TABLE`, regardless of whether there is a foreign key constraint.

For other storage engines, `TRUNCATE TABLE` differs from `DELETE` in the following ways in MySQL 5.1:

- Truncate operations drop and re-create the table, which is much faster than deleting rows one by one.
- Truncate operations are not transaction-safe; an error occurs when attempting one in the course of an active transaction or active table lock.
- The number of deleted rows is not returned.
- As long as the table format file `tbl_name.frm` is valid, the table can be re-created as an empty table with `TRUNCATE TABLE`, even if the data or index files have become corrupted.
- The table handler does not remember the last used `AUTO_INCREMENT` value, but starts counting from the beginning. This is true even for `MyISAM` and `InnoDB`, which normally do not reuse sequence values.
- When used with partitioned tables, `TRUNCATE TABLE` preserves the partitioning; that is, the data and index files are dropped and re-created, while the partition definitions (`.par`) file is unaffected.
- Since truncation of a table does not make any use of `DELETE`, the `TRUNCATE` statement does not invoke `ON DELETE` triggers.

`TRUNCATE TABLE` requires the `DROP` privilege as of MySQL 5.1.16. (Before 5.1.16, it requires the `DELETE` privilege.)

12.2.10. UPDATE Syntax

Single-table syntax:

```
UPDATE [LOW_PRIORITY] [IGNORE] tbl_name
SET col_name1=expr1 [, col_name2=expr2 ...]
```

```
[WHERE where_condition]  
[ORDER BY ...]  
[LIMIT row_count]
```

Multiple-table syntax:

```
UPDATE [LOW_PRIORITY] [IGNORE] table_references  
SET col_name1=expr1 [, col_name2=expr2 ...]  
[WHERE where_condition]
```

For the single-table syntax, the **UPDATE** statement updates columns of existing rows in *tbl_name* with new values. The **SET** clause indicates which columns to modify and the values they should be given. The **WHERE** clause, if given, specifies the conditions that identify which rows to update. With no **WHERE** clause, all rows are updated. If the **ORDER BY** clause is specified, the rows are updated in the order that is specified. The **LIMIT** clause places a limit on the number of rows that can be updated.

For the multiple-table syntax, **UPDATE** updates rows in each table named in *table_references* that satisfy the conditions. In this case, **ORDER BY** and **LIMIT** cannot be used.

where_condition is an expression that evaluates to true for each row to be updated. It is specified as described in [Section 12.2.7, “SELECT Syntax”](#).

The **UPDATE** statement supports the following modifiers:

- If you use the **LOW_PRIORITY** keyword, execution of the **UPDATE** is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (**MyISAM**, **MEMORY**, **MERGE**).
- If you use the **IGNORE** keyword, the update statement does not abort even if errors occur during the update. Rows for which duplicate-key conflicts occur are not updated. Rows for which columns are updated to values that would cause data conversion errors are updated to the closest valid values instead.

If you access a column from *tbl_name* in an expression, **UPDATE** uses the current value of the column. For example, the following statement sets the **age** column to one more than its current value:

```
UPDATE persondata SET age=age+1;
```

Single-table **UPDATE** assignments are generally evaluated from left to right. For multiple-table updates, there is no guarantee that assignments are carried out in any particular order.

If you set a column to the value it currently has, MySQL notices this and does not update it.

If you update a column that has been declared **NOT NULL** by setting to **NULL**, the column is set to the default value appropriate for the data type and the warning count is incremented. The default value is **0** for numeric types, the empty string (**' '**) for string types, and the “zero” value for date and time types.

UPDATE returns the number of rows that were actually changed. The `mysql_info()` C API function returns the number of rows that were matched and updated and the number of warnings that occurred during the **UPDATE**.

You can use **LIMIT row_count** to restrict the scope of the **UPDATE**. A **LIMIT** clause is a rows-matched restriction. The statement stops as soon as it has found *row_count* rows that satisfy the **WHERE** clause, whether or not they actually were changed.

If an **UPDATE** statement includes an **ORDER BY** clause, the rows are updated in the order specified by the clause. This can be useful in certain situations that might otherwise result in an error. Suppose that a table **t** contains a column **id** that has a unique index. The following statement could fail with a duplicate-key error, depending on the order in which rows are updated:

```
UPDATE t SET id = id + 1;
```

For example, if the table contains 1 and 2 in the **id** column and 1 is updated to 2 before 2 is updated to 3, an error occurs. To avoid this problem, add an **ORDER BY** clause to cause the rows with larger **id** values to be updated before those with smaller values:

```
UPDATE t SET id = id + 1 ORDER BY id DESC;
```

You can also perform **UPDATE** operations covering multiple tables. However, you cannot use **ORDER BY** or **LIMIT** with a multiple-table **UPDATE**. The *table_references* clause lists the tables involved in the join. Its syntax is described in [Section 12.2.7.1, “JOIN](#)

[Syntax](#)". Here is an example:

```
UPDATE items,month SET items.price=month.price
WHERE items.id=month.id;
```

The preceding example shows an inner join that uses the comma operator, but multiple-table [UPDATE](#) statements can use any type of join allowed in [SELECT](#) statements, such as [LEFT JOIN](#).

You need the [UPDATE](#) privilege only for columns referenced in a multiple-table [UPDATE](#) that are actually updated. You need only the [SELECT](#) privilege for any columns that are read but not modified.

If you use a multiple-table [UPDATE](#) statement involving [InnoDB](#) tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, update a single table and rely on the [ON UPDATE](#) capabilities that [InnoDB](#) provides to cause the other tables to be modified accordingly. See [Section 13.5.6.4, "FOREIGN KEY Constraints"](#).

Currently, you cannot update a table and select from the same table in a subquery.

12.3. MySQL Utility Statements

12.3.1. DESCRIBE Syntax

```
{DESCRIBE | DESC} tbl_name [col_name | wild]
```

[DESCRIBE](#) provides information about the columns in a table. It is a shortcut for [SHOW COLUMNS FROM](#). These statements also display information for views. (See [Section 12.5.4.4, "SHOW COLUMNS Syntax"](#).)

[col_name](#) can be a column name, or a string containing the SQL [%](#) and [_](#) wildcard characters to obtain output only for the columns with names matching the string. There is no need to enclose the string within quotes unless it contains spaces or other special characters.

```
mysql> DESCRIBE city;
```

Field	Type	Null	Key	Default	Extra
Id	int(11)	NO	PRI	NULL	auto_increment
Name	char(35)	NO			
Country	char(3)	NO	UNI		
District	char(20)	YES	MUL		
Population	int(11)	NO		0	

5 rows in set (0.00 sec)

[Field](#) indicates the column name.

The [Null](#) field indicates whether [NULL](#) values can be stored in the column.

The [Key](#) field indicates whether the column is indexed. A value of [PRI](#) indicates that the column is part of the table's primary key. [UNI](#) indicates that the column is part of a [UNIQUE](#) index. The [MUL](#) value indicates that multiple occurrences of a given value are allowed within the column.

One reason for [MUL](#) to be displayed on a [UNIQUE](#) index is that several columns form a composite [UNIQUE](#) index; although the combination of the columns is unique, each column can still hold multiple occurrences of a given value. Note that in a composite index, only the leftmost column of the index has an entry in the [Key](#) field.

The [Default](#) field indicates the default value that is assigned to the column.

The [Extra](#) field contains any additional information that is available about a given column. In the example shown, the [Extra](#) field indicates that the [Id](#) column was created with the [AUTO_INCREMENT](#) keyword.

If the data types are different from what you expect them to be based on a [CREATE TABLE](#) statement, note that MySQL sometimes changes data types. See [Section 12.1.10.1, "Silent Column Specification Changes"](#).

The [DESCRIBE](#) statement is provided for compatibility with Oracle.

The [SHOW CREATE TABLE](#) and [SHOW TABLE STATUS](#) statements also provide information about tables. See [Section 12.5.4, "SHOW Syntax"](#).

12.3.2. **HELP** Syntax

```
HELP 'search_string'
```

The **HELP** statement returns online information from the MySQL Reference manual. Its proper operation requires that the help tables in the **mysql** database be initialized with help topic information (see [Section 5.2.8, “Server-Side Help”](#)).

The **HELP** statement searches the help tables for the given search string and displays the result of the search. The search string is not case sensitive.

The **HELP** statement understands several types of search strings:

- At the most general level, use **contents** to retrieve a list of the top-level help categories:

```
HELP 'contents'
```

- For a list of topics in a given help category, such as **Data Types**, use the category name:

```
HELP 'data types'
```

- For help on a specific help topic, such as the **ASCII()** function or the **CREATE TABLE** statement, use the associated keyword or keywords:

```
HELP 'ascii'
HELP 'create table'
```

In other words, the search string matches a category, many topics, or a single topic. You cannot necessarily tell in advance whether a given search string will return a list of items or the help information for a single help topic. However, you can tell what kind of response **HELP** returned by examining the number of rows and columns in the result set.

The following descriptions indicate the forms that the result set can take. Output for the example statements is shown using the familiar “tabular” or “vertical” format that you see when using the **mysql** client, but note that **mysql** itself reformats **HELP** result sets in a different way.

- Empty result set

No match could be found for the search string.

- Result set containing a single row with three columns

This means that the search string yielded a hit for the help topic. The result has three columns:

- name**: The topic name.
- description**: Descriptive help text for the topic.
- example**: Usage example or examples. This column might be blank.

Example: **HELP 'replace'**

Yields:

```
name: REPLACE
description: Syntax:
REPLACE(str,from_str,to_str)
```

```
Returns the string str with all occurrences of the string from_str
replaced by the string to_str. REPLACE() performs a case-sensitive
match when searching for from_str.
example: mysql> SELECT REPLACE('www.mysql.com', 'w', 'Ww');
-> 'WwWwWw.mysql.com'
```

- Result set containing multiple rows with two columns

This means that the search string matched many help topics. The result set indicates the help topic names:

- **name**: The help topic name.
- **is_it_category**: **Y** if the name represents a help category, **N** if it does not. If it does not, the **name** value when specified as the argument to the **HELP** statement should yield a single-row result set containing a description for the named item.

Example: **HELP 'status'**

Yields:

name	is_it_category
SHOW	N
SHOW ENGINE	N
SHOW INNODB STATUS	N
SHOW MASTER STATUS	N
SHOW PROCEDURE STATUS	N
SHOW SLAVE STATUS	N
SHOW SLAVE STATUS	N
SHOW TABLE STATUS	N

- Result set containing multiple rows with three columns

This means the search string matches a category. The result set contains category entries:

- **source_category_name**: The help category name.
- **name**: The category or topic name
- **is_it_category**: **Y** if the name represents a help category, **N** if it does not. If it does not, the **name** value when specified as the argument to the **HELP** statement should yield a single-row result set containing a description for the named item.

Example: **HELP 'functions'**

Yields:

source_category_name	name	is_it_category
Functions	CREATE FUNCTION	N
Functions	DROP FUNCTION	N
Functions	Bit Functions	Y
Functions	Comparison operators	Y
Functions	Control flow functions	Y
Functions	Date and Time Functions	Y
Functions	Encryption Functions	Y
Functions	Information Functions	Y
Functions	Logical operators	Y
Functions	Miscellaneous Functions	Y
Functions	Numeric Functions	Y
Functions	String Functions	Y

Before MySQL 5.1.17, if you intend to use the **HELP()** statement while other tables are locked with **LOCK TABLES**, you must also lock the required **mysql.help_XXX** tables. See [Section 12.4.5, “LOCK TABLES and UNLOCK TABLES Syntax”](#).

12.3.3. USE Syntax

USE db_name

The **USE db_name** statement tells MySQL to use the **db_name** database as the default (current) database for subsequent statements. The database remains the default until the end of the session or another **USE** statement is issued:

```
USE db1;
SELECT COUNT(*) FROM mytable;  # selects from db1.mytable
USE db2;
SELECT COUNT(*) FROM mytable;  # selects from db2.mytable
```

Making a particular database the default by means of the `USE` statement does not preclude you from accessing tables in other databases. The following example accesses the `author` table from the `db1` database and the `editor` table from the `db2` database:

```
USE db1;
SELECT author_name, editor_name FROM author, db2.editor
WHERE author.editor_id = db2.editor.editor_id;
```

The `USE` statement is provided for compatibility with Sybase.

12.4. MySQL Transactional and Locking Statements

MySQL supports local transactions (within a given client connection) through statements such as `SET AUTOCOMMIT`, `START TRANSACTION`, `COMMIT`, and `ROLLBACK`. See [Section 12.4.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”](#). XA transaction support enables MySQL to participate in distributed transactions as well. See [Section 12.4.7, “XA Transactions”](#).

12.4.1. START TRANSACTION, COMMIT, and ROLLBACK Syntax

```
START TRANSACTION [WITH CONSISTENT SNAPSHOT] | BEGIN [WORK]
COMMIT [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
ROLLBACK [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
SET AUTOCOMMIT = {0 | 1}
```

The `START TRANSACTION` and `BEGIN` statement begin a new transaction. `COMMIT` commits the current transaction, making its changes permanent. `ROLLBACK` rolls back the current transaction, canceling its changes. The `SET AUTOCOMMIT` statement disables or enables the default autocommit mode for the current connection.

The optional `WORK` keyword is supported for `COMMIT` and `ROLLBACK`, as are the `CHAIN` and `RELEASE` clauses. `CHAIN` and `RELEASE` can be used for additional control over transaction completion. The value of the `completion_type` system variable determines the default completion behavior. See [Section 5.2.3, “System Variables”](#).

The `AND CHAIN` clause causes a new transaction to begin as soon as the current one ends, and the new transaction has the same isolation level as the just-terminated transaction. The `RELEASE` clause causes the server to disconnect the current client connection after terminating the current transaction. Including the `NO` keyword suppresses `CHAIN` or `RELEASE` completion, which can be useful if the `completion_type` system variable is set to cause chaining or release completion by default.

By default, MySQL runs with autocommit mode enabled. This means that as soon as you execute a statement that updates (modifies) a table, MySQL stores the update on disk.

If you are using a transaction-safe storage engine (such as `InnoDB`, or `NDB Cluster`), you can disable autocommit mode with the following statement:

```
SET AUTOCOMMIT=0;
```

After disabling autocommit mode by setting the `AUTOCOMMIT` variable to zero, you must use `COMMIT` to store your changes to disk or `ROLLBACK` if you want to ignore the changes you have made since the beginning of your transaction.

To disable autocommit mode for a single series of statements, use the `START TRANSACTION` statement:

```
START TRANSACTION;
SELECT @A:=SUM(salary) FROM table1 WHERE type=1;
UPDATE table2 SET summary=@A WHERE type=1;
COMMIT;
```

With `START TRANSACTION`, autocommit remains disabled until you end the transaction with `COMMIT` or `ROLLBACK`. The autocommit mode then reverts to its previous state.

`BEGIN` and `BEGIN WORK` are supported as aliases of `START TRANSACTION` for initiating a transaction. `START TRANSACTION` is standard SQL syntax and is the recommended way to start an ad-hoc transaction.

Important

Many APIs used for writing MySQL client applications (such as JDBC) provide their own methods for starting transactions that can (and sometimes should) be used instead of sending a `START TRANSACTION` statement from the client. See [Chapter 25, APIs and Libraries](#), or the documentation for your API, for more information.

The **BEGIN** statement differs from the use of the **BEGIN** keyword that starts a **BEGIN . . . END** compound statement. The latter does not begin a transaction. See [Section 19.2.5, “BEGIN . . . END Compound Statement Syntax”](#).

You can also begin a transaction like this:

```
START TRANSACTION WITH CONSISTENT SNAPSHOT;
```

The **WITH CONSISTENT SNAPSHOT** clause starts a consistent read for storage engines that are capable of it. Currently, this applies only to **InnoDB**. The effect is the same as issuing a **START TRANSACTION** followed by a **SELECT** from any **InnoDB** table. See [Section 13.5.10.4, “Consistent Non-Locking Read”](#).

The **WITH CONSISTENT SNAPSHOT** clause does not change the current transaction isolation level, so it provides a consistent snapshot only if the current isolation level is one that allows consistent read (**REPEATABLE READ** or **SERIALIZABLE**).

Beginning a transaction causes any pending transaction to be committed. See [Section 12.4.3, “Statements That Cause an Implicit Commit”](#), for more information.

Beginning a transaction also causes table locks acquired with **LOCK TABLES** to be released, as though you had executed **UNLOCK TABLES**. Beginning a transaction does not release a global read lock acquired with **FLUSH TABLES WITH READ LOCK**.

For best results, transactions should be performed using only tables managed by a single transactional storage engine. Otherwise, the following problems can occur:

- If you use tables from more than one transaction-safe storage engine (such as **InnoDB** and **Falcon**), and the transaction isolation level is not **SERIALIZABLE**, it is possible that when one transaction commits, another ongoing transaction that uses the same tables will see only some of the changes made by the first transaction. That is, the atomicity of transactions is not guaranteed with mixed engines and inconsistencies can result. (If mixed-engine transactions are infrequent, you can use **SET TRANSACTION ISOLATION LEVEL** to set the isolation level to **SERIALIZABLE** on a per-transaction basis as necessary.)
- If you use non-transaction-safe tables within a transaction, any changes to those tables are stored at once, regardless of the status of autocommit mode.

If you issue a **ROLLBACK** statement after updating a non-transactional table within a transaction, an **ER_WARNING_NOT_COMPLETE_ROLLBACK** warning occurs. Changes to transaction-safe tables are rolled back, but not changes to non-transaction-safe tables.

Each transaction is stored in the binary log in one chunk, upon **COMMIT**. Transactions that are rolled back are not logged. (**Exception:** Modifications to non-transactional tables cannot be rolled back. If a transaction that is rolled back includes modifications to non-transactional tables, the entire transaction is logged with a **ROLLBACK** statement at the end to ensure that the modifications to those tables are replicated.) See [Section 5.11.4, “The Binary Log”](#).

You can change the isolation level for transactions with **SET TRANSACTION ISOLATION LEVEL**. See [Section 12.4.6, “SET TRANSACTION Syntax”](#).

Rolling back can be a slow operation that may occur without the user having explicitly asked for it (for example, when an error occurs). Because of this, **SHOW PROCESSLIST** displays **Rolling back** in the **State** column for the connection during implicit and explicit (**ROLLBACK** SQL statement) rollbacks.

12.4.2. Statements That Cannot Be Rolled Back

Some statements cannot be rolled back. In general, these include data definition language (DDL) statements, such as those that create or drop databases, those that create, drop, or alter tables or stored routines.

You should design your transactions not to include such statements. If you issue a statement early in a transaction that cannot be rolled back, and then another statement later fails, the full effect of the transaction cannot be rolled back in such cases by issuing a **ROLLBACK** statement.

12.4.3. Statements That Cause an Implicit Commit

Each of the following statements (and any synonyms for them) implicitly end a transaction, as if you had done a **COMMIT** before executing the statement:

- `ALTER EVENT`, `ALTER FUNCTION`, `ALTER FUNCTION`, `ALTER PROCEDURE`, `ALTER TABLE`, `BEGIN`, `CREATE DATABASE`, `CREATE EVENT`, `CREATE FUNCTION`, `CREATE INDEX`, `CREATE PROCEDURE`, `CREATE TABLE`, `DROP DATABASE`, `DROP EVENT`, `DROP FUNCTION`, `DROP INDEX`, `DROP PROCEDURE`, `DROP TABLE`, `LOAD DATA INFILE`, `LOCK TABLES`, `RENAME TABLE`, `SET AUTOCOMMIT=1`, `START TRANSACTION`, `TRUNCATE TABLE`, `UNLOCK TABLES`.

The `BEGIN` statement differs from the use of the `BEGIN` keyword that starts a `BEGIN . . . END` compound statement. The latter does not cause an implicit commit. See [Section 19.2.5, “BEGIN . . . END Compound Statement Syntax”](#).

- Beginning with MySQL 5.1.3, `ALTER VIEW`, `CREATE TRIGGER`, `CREATE USER`, `CREATE VIEW`, `DROP TRIGGER`, `DROP USER`, `DROP VIEW`, and `RENAME USER` cause an implicit commit.
- `UNLOCK TABLES` commits a transaction only if any tables currently have been locked with `LOCK TABLES`. This does not occur for `UNLOCK TABLES` following `FLUSH TABLES WITH READ LOCK` because the latter statement does not acquire table-level locks.
- The `CREATE TABLE` statement in `InnoDB` is processed as a single transaction. This means that a `ROLLBACK` from the user does not undo `CREATE TABLE` statements the user made during that transaction.
- `CREATE TABLE` and `DROP TABLE` do not commit a transaction if the `TEMPORARY` keyword is used. (This does not apply to other operations on temporary tables such as `CREATE INDEX`, which do cause a commit.)
- In MySQL 5.1.11 and earlier, `LOAD DATA INFILE` caused an implicit commit for all storage engines. Beginning with MySQL 5.1.12, it causes an implicit commit only for tables using the `NDB` storage engine. For more information, see [Bug#11151](#).
- Beginning with MySQL 5.1.15, `CREATE TABLE . . . SELECT` causes an implicit commit before and after the statement is executed when you are creating non-temporary tables. (No commit occurs for `CREATE TEMPORARY TABLE . . . SELECT`.) This is to prevent an issue during replication where the table could be created on the master after a rollback, but fail to be recorded in the binary log, and therefore not replicated to the slave. For more information, see [Bug#22865](#).

Transactions cannot be nested. This is a consequence of the implicit `COMMIT` performed for any current transaction when you issue a `START TRANSACTION` statement or one of its synonyms.

Statements that cause implicit cannot be used in an XA transaction while the transaction is in an `ACTIVE` state.

12.4.4. SAVEPOINT and ROLLBACK TO SAVEPOINT Syntax

```
SAVEPOINT identifier
ROLLBACK [WORK] TO SAVEPOINT identifier
RELEASE SAVEPOINT identifier
```

`InnoDB` supports the SQL statements `SAVEPOINT`, `ROLLBACK TO SAVEPOINT`, `RELEASE SAVEPOINT` and the optional `WORK` keyword for `ROLLBACK`.

The `SAVEPOINT` statement sets a named transaction savepoint with a name of *identifier*. If the current transaction has a savepoint with the same name, the old savepoint is deleted and a new one is set.

The `ROLLBACK TO SAVEPOINT` statement rolls back a transaction to the named savepoint. Modifications that the current transaction made to rows after the savepoint was set are undone in the rollback, but `InnoDB` does *not* release the row locks that were stored in memory after the savepoint. (Note that for a new inserted row, the lock information is carried by the transaction ID stored in the row; the lock is not separately stored in memory. In this case, the row lock is released in the undo.) Savepoints that were set at a later time than the named savepoint are deleted.

If the `ROLLBACK TO SAVEPOINT` statement returns the following error, it means that no savepoint with the specified name exists:

```
ERROR 1181: Got error 153 during ROLLBACK
```

The `RELEASE SAVEPOINT` statement removes the named savepoint from the set of savepoints of the current transaction. No commit or rollback occurs. It is an error if the savepoint does not exist.

All savepoints of the current transaction are deleted if you execute a `COMMIT`, or a `ROLLBACK` that does not name a savepoint.

Beginning with MySQL 5.0.17, a new savepoint level is created when a stored function is invoked or a trigger is activated. The savepoints on previous levels become unavailable and thus do not conflict with savepoints on the new level. When the function or trigger terminates, any savepoints it created are released and the previous savepoint level is restored.

12.4.5. LOCK TABLES and UNLOCK TABLES Syntax

```
LOCK TABLES
    tbl_name [[AS] alias] lock_type
    [, tbl_name [[AS] alias] lock_type] ...

lock_type:
    READ [LOCAL]
    | [LOW_PRIORITY] WRITE

UNLOCK TABLES
```

LOCK TABLES locks base tables (but not views) for the current thread. To use **LOCK TABLES**, you must have the **LOCK TABLES** privilege, and the **SELECT** privilege for each table to be locked.

UNLOCK TABLES explicitly releases any table locks held by the current thread. Another use for **UNLOCK TABLES** is to release the global read lock acquired with **FLUSH TABLES WITH READ LOCK**. (You can lock all tables in all databases with read locks with the **FLUSH TABLES WITH READ LOCK** statement. See [Section 12.5.5.2, “FLUSH Syntax”](#). This is a very convenient way to get backups if you have a filesystem such as Veritas that can take snapshots in time.)

The following general rules apply to acquisition and release of locks by a given thread:

- Table locks are acquired with **LOCK TABLES**.
- If the **LOCK TABLES** statement must wait due to locks held by other threads on any of the tables, it blocks until all locks can be acquired.
- Table locks are released explicitly with **UNLOCK TABLES**.
- Table locks are released implicitly under these conditions:
 - **LOCK TABLES** releases any table locks currently held by the thread before acquiring new locks.
 - Beginning a transaction (for example, with **START TRANSACTION**) implicitly performs an **UNLOCK TABLES**. (Additional information about the interaction between table locking and transactions is given later in the section.)
 - If a client connection drops, the server releases table locks held by the client. If the client reconnects, the locks will no longer be in effect. For this reason, clients may wish to disable auto-reconnect. With auto-reconnect in effect, the client is not notified if reconnect occurs but any table locks will have been lost. With auto-reconnect disabled, if the connection drops, an error occurs for the next statement issued. The client can detect the error and take appropriate action such as reacquiring the locks. See [Section 25.2.13, “Controlling Automatic Reconnect Behavior”](#).
- One thread cannot release another thread's locks.

Note

If you use **ALTER TABLE** on a locked table, it may become unlocked. See [Section B.1.7.1, “Problems with ALTER TABLE”](#).

The main reasons to use **LOCK TABLES** are to emulate transactions or to get more speed when updating tables. This is explained in more detail later in this section.

A table lock protects only against inappropriate reads or writes by other clients. The client holding the lock, even a read lock, can perform table-level operations such as **DROP TABLE**. Truncate operations are not transaction-safe, so an error occurs if the client attempts one during an active transaction or while holding a table lock.

When you use **LOCK TABLES**, you must lock all tables that you are going to use in your statements. While the locks obtained with a **LOCK TABLES** statement are in effect, you cannot access any tables that were not locked by the statement. Because **LOCK TABLES** will not lock views, if the operation that you are performing uses any views, you must also lock all base tables on which those views depend.

You cannot use a locked table multiple times in a single query. Use aliases instead, in which case you must obtain a lock for each alias separately:

```
mysql> LOCK TABLE t WRITE, t AS t1 WRITE;
mysql> INSERT INTO t SELECT * FROM t;
ERROR 1100: Table 't' was not locked with LOCK TABLES
```

```
mysql> INSERT INTO t SELECT * FROM t AS t1;
```

If your statements refer to a table by means of an alias, you must lock the table using that same alias. It does not work to lock the table without specifying the alias:

```
mysql> LOCK TABLE t READ;
mysql> SELECT * FROM t AS myalias;
ERROR 1100: Table 'myalias' was not locked with LOCK TABLES
```

Conversely, if you lock a table using an alias, you must refer to it in your statements using that alias:

```
mysql> LOCK TABLE t AS myalias READ;
mysql> SELECT * FROM t;
ERROR 1100: Table 't' was not locked with LOCK TABLES
mysql> SELECT * FROM t AS myalias;
```

If a thread obtains a **READ** lock on a table, that thread (and all other threads) can only read from the table. If a thread obtains a **WRITE** lock on a table, only the thread holding the lock can write to the table. Other threads are blocked from reading or writing the table until the lock has been released.

The difference between **READ LOCAL** and **READ** is that **READ LOCAL** allows non-conflicting **INSERT** statements (concurrent inserts) to execute while the lock is held. However, **READ LOCAL** cannot be used if you are going to manipulate the database using processes external to the server while you hold the lock. For **InnoDB** tables, **READ LOCAL** is the same as **READ**.

WRITE locks normally have higher priority than **READ** locks to ensure that updates are processed as soon as possible. This means that if one thread obtains a **READ** lock and then another thread requests a **WRITE** lock, subsequent **READ** lock requests wait until the **WRITE** thread has gotten the lock and released it. You can use **LOW_PRIORITY WRITE** locks to allow other threads to obtain **READ** locks before the thread that is waiting for the **WRITE** lock. You should use **LOW_PRIORITY WRITE** locks only if you are sure that eventually there will be a time when no threads have a **READ** lock. (Exception: For **InnoDB** tables in transactional mode (autocommit = 0), a **LOW_PRIORITY WRITE** lock acts like a regular **WRITE** lock and precedes waiting **READ** locks.)

LOCK TABLES works as follows:

1. Sort all tables to be locked in an internally defined order. From the user standpoint, this order is undefined.
2. If a table is to be locked with a read and a write lock, put the write lock request before the read lock request.
3. Lock one table at a time until the thread gets all locks.

This policy ensures that table locking is deadlock free. There are, however, other things you need to be aware of about this policy: If you are using a **LOW_PRIORITY WRITE** lock for a table, it means only that MySQL waits for this particular lock until there are no threads that want a **READ** lock. When the thread has gotten the **WRITE** lock and is waiting to get the lock for the next table in the lock table list, all other threads wait for the **WRITE** lock to be released. If this becomes a serious problem with your application, you should consider converting some of your tables to transaction-safe tables.

For some operations, system tables in the **mysql** database must be accessed. For example, the **HELP** statement requires the contents of the server-side help tables, and **CONVERT_TZ()** might need to read the time zone tables. Before MySQL 5.1.17, to perform such operations while a **LOCK TABLES** statement is in effect, you must also lock the requisite system tables explicitly or a lock error occurs. As of 5.1.17, the server implicitly locks the system tables for reading as necessary so that you need not lock them explicitly. These tables are treated as just described:

```
mysql.help_category
mysql.help_keyword
mysql.help_relation
mysql.help_topic
mysql.proc
mysql.time_zone
mysql.time_zone_leap_second
mysql.time_zone_name
mysql.time_zone_transition
mysql.time_zone_transition_type
```

If you want to explicitly place a **WRITE** lock on any of those tables with a **LOCK TABLES** statement, the table must be the only one locked; no other table can be locked with the same statement.

LOCK TABLES and **UNLOCK TABLES** interact with the use of transactional tables as follows:

- **LOCK TABLES** is not transaction-safe and implicitly commits any active transaction before attempting to lock the tables. Also, beginning a transaction (for example, with **START TRANSACTION**) implicitly performs an **UNLOCK TABLES**. (See [Section 12.4.3, “Statements That Cause an Implicit Commit”](#).)
- **UNLOCK TABLES** implicitly commits any active transaction, but only if any tables have been locked with **LOCK TABLES**.
- The correct way to use **LOCK TABLES** and **UNLOCK TABLES** with transactional tables, such as **InnoDB** tables, is to set **AUTO-COMMIT = 0** and not to call **UNLOCK TABLES** until you commit the transaction explicitly. When you call **LOCK TABLES**, **InnoDB** internally takes its own table lock, and MySQL takes its own table lock. **InnoDB** releases its table lock at the next commit, but for MySQL to release its table lock, you have to call **UNLOCK TABLES**. You should not have **AUTOCOMMIT = 1**, because then **InnoDB** releases its table lock immediately after the call of **LOCK TABLES**, and deadlocks can very easily happen. Note that we do not acquire the **InnoDB** table lock at all if **AUTOCOMMIT=1**, to help old applications avoid unnecessary deadlocks.
- **ROLLBACK** does not release MySQL's non-transactional table locks.
- **FLUSH TABLES WITH READ LOCK** acquires a global read lock and not table locks, so it is not subject to the same behavior as **LOCK TABLES** and **UNLOCK TABLES** with respect to table locking and implicit commits. See [Section 12.5.5.2, “FLUSH Syntax”](#).

You can safely use **KILL** to terminate a thread that is waiting for a table lock. See [Section 12.5.5.3, “KILL Syntax”](#).

Note that you should *not* lock any tables that you are using with **INSERT DELAYED** because in that case the **INSERT** is performed by a separate thread.

Normally, you do not need to lock tables, because all single **UPDATE** statements are atomic; no other thread can interfere with any other currently executing SQL statement. However, there are a few cases when locking tables may provide an advantage:

- If you are going to run many operations on a set of **MyISAM** tables, it is much faster to lock the tables you are going to use. Locking **MyISAM** tables speeds up inserting, updating, or deleting on them because MySQL does not flush the key cache for the locked tables until **UNLOCK TABLES** is called. Normally, the key cache is flushed after each SQL statement.

The downside to locking the tables is that no thread can update a **READ**-locked table (including the one holding the lock) and no thread can access a **WRITE**-locked table other than the one holding the lock.

- If you are using tables for a non-transactional storage engine, you must use **LOCK TABLES** if you want to ensure that no other thread modifies the tables between a **SELECT** and an **UPDATE**. The example shown here requires **LOCK TABLES** to execute safely:

```
LOCK TABLES trans READ, customer WRITE;
SELECT SUM(value) FROM trans WHERE customer_id=some_id;
UPDATE customer
  SET total_value=sum_from_previous_statement
  WHERE customer_id=some_id;
UNLOCK TABLES;
```

Without **LOCK TABLES**, it is possible that another thread might insert a new row in the **trans** table between execution of the **SELECT** and **UPDATE** statements.

You can avoid using **LOCK TABLES** in many cases by using relative updates (**UPDATE customer SET value=value+new_value**) or the **LAST_INSERT_ID()** function. See [Section 1.9.5.2, “Transactions and Atomic Operations”](#).

You can also avoid locking tables in some cases by using the user-level advisory lock functions **GET_LOCK()** and **RELEASE_LOCK()**. These locks are saved in a hash table in the server and implemented with **pthread_mutex_lock()** and **pthread_mutex_unlock()** for high speed. See [Section 11.11.4, “Miscellaneous Functions”](#).

See [Section 6.3.1, “Internal Locking Methods”](#), for more information on locking policy.

12.4.6. SET TRANSACTION Syntax

```
SET [GLOBAL | SESSION] TRANSACTION ISOLATION LEVEL
{ READ UNCOMMITTED | READ COMMITTED | REPEATABLE READ | SERIALIZABLE }
```

This statement sets the transaction isolation level for the next transaction, globally, or for the current session.

The default behavior of `SET TRANSACTION` is to set the isolation level for the next (not yet started) transaction. If you use the `GLOBAL` keyword, the statement sets the default transaction level globally for all new connections created from that point on. Existing connections are unaffected. You need the `SUPER` privilege to do this. Using the `SESSION` keyword sets the default transaction level for all future transactions performed on the current connection.

For descriptions of each `InnoDB` transaction isolation level, see [Section 13.5.10.3, “InnoDB and TRANSACTION ISOLATION LEVEL”](#). `InnoDB` supports each of these levels in MySQL 5.1. The default level is `REPEATABLE READ`.

In MySQL 5.1, if the `READ COMMITTED` isolation level is used or the `innodb_locks_unsafe_for_binlog` system variable is enabled, there is no `InnoDB` gap locking except in constraint checking. Also, record locks for non-matching rows are released after MySQL has evaluated the `WHERE` condition.

To set the initial default global isolation level for `mysqld`, use the `--transaction-isolation` option. See [Section 5.2.2, “Command Options”](#).

12.4.7. XA Transactions

Support for XA transactions is available for the `InnoDB` storage engine. The MySQL XA implementation is based on the X/Open CAE document *Distributed Transaction Processing: The XA Specification*. This document is published by The Open Group and available at <http://www.opengroup.org/public/pubs/catalog/c193.htm>. Limitations of the current XA implementation are described in [Section D.5, “Restrictions on XA Transactions”](#).

On the client side, there are no special requirements. The XA interface to a MySQL server consists of SQL statements that begin with the `XA` keyword. MySQL client programs must be able to send SQL statements and to understand the semantics of the XA statement interface. They do not need be linked against a recent client library. Older client libraries also will work.

Currently, among the MySQL Connectors, MySQL Connector/J 5.0.0 supports XA directly (by means of a class interface that handles the XA SQL statement interface for you).

XA supports distributed transactions; that is, the ability to allow multiple separate transactional resources to participate in a global transaction. Transactional resources often are RDBMSs but may be other kinds of resources.

A global transaction involves several actions that are transactional in themselves, but that all must either complete successfully as a group, or all be rolled back as a group. In essence, this extends ACID properties “up a level” so that multiple ACID transactions can be executed in concert as components of a global operation that also has ACID properties. (However, for a distributed transaction, you must use the `SERIALIZABLE` isolation level to achieve ACID properties. It is enough to use `REPEATABLE READ` for a non-distributed transaction, but not for a distributed transaction.)

Some examples of distributed transactions:

- An application may act as an integration tool that combines a messaging service with an RDBMS. The application makes sure that transactions dealing with message sending, retrieval, and processing that also involve a transactional database all happen in a global transaction. You can think of this as “transactional email.”
- An application performs actions that involve different database servers, such as a MySQL server and an Oracle server (or multiple MySQL servers), where actions that involve multiple servers must happen as part of a global transaction, rather than as separate transactions local to each server.
- A bank keeps account information in an RDBMS and distributes and receives money via automated teller machines (ATMs). It is necessary to ensure that ATM actions are correctly reflected in the accounts, but this cannot be done with the RDBMS alone. A global transaction manager integrates the ATM and database resources to ensure overall consistency of financial transactions.

Applications that use global transactions involve one or more Resource Managers and a Transaction Manager:

- A Resource Manager (RM) provides access to transactional resources. A database server is one kind of resource manager. It must be possible to either commit or roll back transactions managed by the RM.
- A Transaction Manager (TM) coordinates the transactions that are part of a global transaction. It communicates with the RMs that handle each of these transactions. The individual transactions within a global transaction are “branches” of the global transaction. Global transactions and their branches are identified by a naming scheme described later.

The MySQL implementation of XA MySQL enables a MySQL server to act as a Resource Manager that handles XA transactions within a global transaction. A client program that connects to the MySQL server acts as the Transaction Manager.

To carry out a global transaction, it is necessary to know which components are involved, and bring each component to a point when it can be committed or rolled back. Depending on what each component reports about its ability to succeed, they must all commit or roll back as an atomic group. That is, either all components must commit, or all components must roll back. To manage a global transaction, it is necessary to take into account that any component or the connecting network might fail.

The process for executing a global transaction uses two-phase commit (2PC). This takes place after the actions performed by the branches of the global transaction have been executed.

1. In the first phase, all branches are prepared. That is, they are told by the TM to get ready to commit. Typically, this means each RM that manages a branch records the actions for the branch in stable storage. The branches indicate whether they are able to do this, and these results are used for the second phase.
2. In the second phase, the TM tells the RMs whether to commit or roll back. If all branches indicated when they were prepared that they will be able to commit, all branches are told to commit. If any branch indicated when it was prepared that it will not be able to commit, all branches are told to roll back.

In some cases, a global transaction might use one-phase commit (1PC). For example, when a Transaction Manager finds that a global transaction consists of only one transactional resource (that is, a single branch), that resource can be told to prepare and commit at the same time.

12.4.7.1. XA Transaction SQL Syntax

To perform XA transactions in MySQL, use the following statements:

```
XA {START|BEGIN} xid [JOIN|RESUME]
XA END xid [SUSPEND [FOR MIGRATE]]
XA PREPARE xid
XA COMMIT xid [ONE PHASE]
XA ROLLBACK xid
XA RECOVER
```

For **XA START**, the **JOIN** and **RESUME** clauses are not supported.

For **XA END** the **SUSPEND [FOR MIGRATE]** clause is not supported.

Each XA statement begins with the **XA** keyword, and most of them require an *xid* value. An *xid* is an XA transaction identifier. It indicates which transaction the statement applies to. *xid* values are supplied by the client, or generated by the MySQL server. An *xid* value has from one to three parts:

```
xid: gtrid [, bqual [, formatID ]]
```

gtrid is a global transaction identifier, *bqual* is a branch qualifier, and *formatID* is a number that identifies the format used by the *gtrid* and *bqual* values. As indicated by the syntax, *bqual* and *formatID* are optional. The default *bqual* value is `' '` if not given. The default *formatID* value is 1 if not given.

gtrid and *bqual* must be string literals, each up to 64 bytes (not characters) long. *gtrid* and *bqual* can be specified in several ways. You can use a quoted string (`'ab'`), hex string (`0x6162`, `X'ab'`), or bit value (`b'nnnn'`).

formatID is an unsigned integer.

The *gtrid* and *bqual* values are interpreted in bytes by the MySQL server's underlying XA support routines. However, while an SQL statement containing an XA statement is being parsed, the server works with some specific character set. To be safe, write *gtrid* and *bqual* as hex strings.

xid values typically are generated by the Transaction Manager. Values generated by one TM must be different from values generated by other TMs. A given TM must be able to recognize its own *xid* values in a list of values returned by the **XA RECOVER** statement.

MySQL Enterprise

For expert advice on XA Distributed Transaction Support subscribe to the MySQL Enterprise Monitor. For more information see, <http://www.mysql.com/products/enterprise/advisors.html>.

XA START *xid* starts an XA transaction with the given *xid* value. Each XA transaction must have a unique *xid* value, so the value must not currently be used by another XA transaction. Uniqueness is assessed using the *gtrid* and *bqual* values. All following XA statements for the XA transaction must be specified using the same *xid* value as that given in the **XA START** statement. If you use any of those statements but specify an *xid* value that does not correspond to some existing XA transaction, an error occurs.

One or more XA transactions can be part of the same global transaction. All XA transactions within a given global transaction must use the same *gtrid* value in the *xid* value. For this reason, *gtrid* values must be globally unique so that there is no ambiguity about which global transaction a given XA transaction is part of. The *bqual* part of the *xid* value must be different for each XA transaction within a global transaction. (The requirement that *bqual* values be different is a limitation of the current MySQL XA implementation. It is not part of the XA specification.)

The **XA RECOVER** statement returns information for those XA transactions on the MySQL server that are in the **PREPARED** state. (See [Section 12.4.7.2, “XA Transaction States”](#).) The output includes a row for each such XA transaction on the server, regardless of which client started it.

XA RECOVER output rows look like this (for an example *xid* value consisting of the parts 'abc', 'def', and 7):

```
mysql> XA RECOVER;
+-----+-----+-----+-----+
| formatID | gtrid_length | bqual_length | data |
+-----+-----+-----+-----+
| 7 | 3 | 3 | abcdef |
+-----+-----+-----+-----+
```

The output columns have the following meanings:

- *formatID* is the *formatID* part of the transaction *xid*
- *gtrid_length* is the length in bytes of the *gtrid* part of the *xid*
- *bqual_length* is the length in bytes of the *bqual* part of the *xid*
- *data* is the concatenation of the *gtrid* and *bqual* parts of the *xid*

12.4.7.2. XA Transaction States

An XA transaction progresses through the following states:

1. Use **XA START** to start an XA transaction and put it in the **ACTIVE** state.
2. For an **ACTIVE** XA transaction, issue the SQL statements that make up the transaction, and then issue an **XA END** statement. **XA END** puts the transaction in the **IDLE** state.
3. For an **IDLE** XA transaction, you can issue either an **XA PREPARE** statement or an **XA COMMIT ... ONE PHASE** statement:
 - **XA PREPARE** puts the transaction in the **PREPARED** state. An **XA RECOVER** statement at this point will include the transaction's *xid* value in its output, because **XA RECOVER** lists all XA transactions that are in the **PREPARED** state.
 - **XA COMMIT ... ONE PHASE** prepares and commits the transaction. The *xid* value will not be listed by **XA RECOVER** because the transaction terminates.
4. For a **PREPARED** XA transaction, you can issue an **XA COMMIT** statement to commit and terminate the transaction, or **XA ROLLBACK** to roll back and terminate the transaction.

Here is a simple XA transaction that inserts a row into a table as part of a global transaction:

```
mysql> XA START 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO mytable (i) VALUES(10);
```

```
Query OK, 1 row affected (0.04 sec)

mysql> XA END 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> XA PREPARE 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> XA COMMIT 'xatest';
Query OK, 0 rows affected (0.00 sec)
```

Within the context of a given client connection, XA transactions and local (non-XA) transactions are mutually exclusive. For example, if **XA START** has been issued to begin an XA transaction, a local transaction cannot be started until the XA transaction has been committed or rolled back. Conversely, if a local transaction has been started with **START TRANSACTION**, no XA statements can be used until the transaction has been committed or rolled back.

Note that if an XA transaction is in the **ACTIVE** state, you cannot issue any statements that cause an implicit commit. That would violate the XA contract because you could not roll back the XA transaction. You will receive the following error if you try to execute such a statement:

```
ERROR 1399 (XAE07): XAER_RMFAIL: The command cannot be executed
when global transaction is in the ACTIVE state
```

Statements to which the preceding remark applies are listed at [Section 12.4.3, “Statements That Cause an Implicit Commit”](#).

12.5. Database Administration Statements

12.5.1. Account Management Statements

MySQL account information is stored in the tables of the `mysql` database. This database and the access control system are discussed extensively in [Chapter 5, Database Administration](#), which you should consult for additional details.

Important

Some releases of MySQL introduce changes to the structure of the grant tables to add new privileges or features. Whenever you update to a new version of MySQL, you should update your grant tables to make sure that they have the current structure so that you can take advantage of any new capabilities. See [Section 5.5.7, “mysql_upgrade — Check Tables for MySQL Upgrade”](#).

MySQL Enterprise

In a production environment it is always prudent to examine any changes to users' accounts. The MySQL Enterprise Monitor provides notification whenever users' privileges are altered. For more information see, <http://www.mysql.com/products/enterprise/advisors.html>.

12.5.1.1. CREATE USER Syntax

```
CREATE USER user [IDENTIFIED BY [PASSWORD] 'password']
[, user [IDENTIFIED BY [PASSWORD] 'password']] ...
```

The **CREATE USER** statement creates new MySQL accounts. To use it, you must have the global **CREATE USER** privilege or the **INSERT** privilege for the `mysql` database. For each account, **CREATE USER** creates a new row in the `mysql.user` table that has no privileges. An error occurs if the account already exists. Each account is named using the same format as for the **GRANT** statement; for example, `'jeffrey'@'localhost'`. If you specify only the username part of the account name, a hostname part of `'%'` is used. For additional information about specifying account names, see [Section 12.5.1.3, “GRANT Syntax”](#).

The account can be given a password with the optional **IDENTIFIED BY** clause. The *user* value and the password are given the same way as for the **GRANT** statement. In particular, to specify the password in plain text, omit the **PASSWORD** keyword. To specify the password as the hashed value as returned by the **PASSWORD()** function, include the **PASSWORD** keyword. See [Section 12.5.1.3, “GRANT Syntax”](#).

12.5.1.2. DROP USER Syntax

```
DROP USER user [, user] ...
```

The **DROP USER** statement removes one or more MySQL accounts. It removes privilege rows for the account from all grant tables. To

use this statement, you must have the global **CREATE USER** privilege or the **DELETE** privilege for the `mysql` database. Each account is named using the same format as for the **GRANT** statement; for example, `'jeffrey'@'localhost'`. If you specify only the user-name part of the account name, a hostname part of `'%'` is used. For additional information about specifying account names, see [Section 12.5.1.3, “GRANT Syntax”](#).

With **DROP USER**, you can remove an account and its privileges as follows:

```
DROP USER user;
```

Important

DROP USER does not automatically close any open user sessions. Rather, in the event that a user with an open session is dropped, the statement does not take effect until that user's session is closed. Once the session is closed, the user is dropped, and that user's next attempt to log in will fail. *This is by design.*

DROP USER does not automatically delete or invalidate any database objects that the user created. This applies to tables, views, stored routines, triggers, and events.

12.5.1.3. GRANT Syntax

```
GRANT priv_type [(column_list)] [, priv_type [(column_list)]] ...
ON [object_type] {tbl_name | * | *.* | db_name.*}
TO user [IDENTIFIED BY [PASSWORD] 'password']
    [, user [IDENTIFIED BY [PASSWORD] 'password']] ...
[REQUIRE
    NONE |
    [{SSL | X509}]
    [CIPHER 'cipher' [AND]]
    [ISSUER 'issuer' [AND]]
    [SUBJECT 'subject']]
[WITH with_option [with_option] ...]

object_type =
TABLE
|
FUNCTION
|
PROCEDURE

with_option =
GRANT OPTION
|
MAX_QUERIES_PER_HOUR count
|
MAX_UPDATES_PER_HOUR count
|
MAX_CONNECTIONS_PER_HOUR count
|
MAX_USER_CONNECTIONS count
```

The **GRANT** statement enables system administrators to create MySQL user accounts and to grant rights to from accounts. To use **GRANT**, you must have the **GRANT OPTION** privilege, and you must have the privileges that you are granting. The **REVOKE** statement is related and enables administrators to remove account privileges. See [Section 12.5.1.5, “REVOKE Syntax”](#).

MySQL Enterprise

For automated notification of users with inappropriate privileges, subscribe to the MySQL Enterprise Monitor. For more information see <http://www.mysql.com/products/enterprise/advisors.html>.

MySQL account information is stored in the tables of the `mysql` database. This database and the access control system are discussed extensively in [Chapter 5, Database Administration](#), which you should consult for additional details.

Important

Some releases of MySQL introduce changes to the structure of the grant tables to add new privileges or features. Whenever you update to a new version of MySQL, you should update your grant tables to make sure that they have the current structure so that you can take advantage of any new capabilities. See [Section 5.5.7, “mysql_upgrade — Check Tables for MySQL Upgrade”](#).

If the grant tables hold privilege rows that contain mixed-case database or table names and the `lower_case_table_names` system variable is set to a non-zero value, **REVOKE** cannot be used to revoke these privileges. It will be necessary to manipulate the grant tables directly. (**GRANT** will not create such rows when `lower_case_table_names` is set, but such rows might have been created prior to setting the variable.)

Privileges can be granted at several levels. The examples shown here include no **IDENTIFIED BY 'password'** clause for brevity, but you should include one if the account does not already exist to avoid creating an account with no password.

- **Global level**

Global privileges apply to all databases on a given server. These privileges are stored in the `mysql.user` table. `GRANT ALL ON *.*` and `REVOKE ALL ON *.*` grant and revoke only global privileges.

```
GRANT ALL ON *.* TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON *.* TO 'someuser'@'somehost';
```

- **Database level**

Database privileges apply to all objects in a given database. These privileges are stored in the `mysql.db` and `mysql.host` tables. `GRANT ALL ON db_name.*` and `REVOKE ALL ON db_name.*` grant and revoke only database privileges.

```
GRANT ALL ON mydb.* TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON mydb.* TO 'someuser'@'somehost';
```

- **Table level**

Table privileges apply to all columns in a given table. These privileges are stored in the `mysql.tables_priv` table. `GRANT ALL ON db_name.tbl_name` and `REVOKE ALL ON db_name.tbl_name` grant and revoke only table privileges.

```
GRANT ALL ON mydb.mytbl TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON mydb.mytbl TO 'someuser'@'somehost';
```

- **Column level**

Column privileges apply to single columns in a given table. These privileges are stored in the `mysql.columns_priv` table. When using `REVOKE`, you must specify the same columns that were granted. The column or columns for which the privileges are to be granted must be enclosed within parentheses.

```
GRANT SELECT (col1), INSERT (col1,col2) ON mydb.mytbl TO 'someuser'@'somehost';
```

- **Routine level**

The `CREATE ROUTINE`, `ALTER ROUTINE`, `EXECUTE`, and `GRANT` privileges apply to stored routines (functions and procedures). They can be granted at the global and database levels. Also, except for `CREATE ROUTINE`, these privileges can be granted at the routine level for individual routines and are stored in the `mysql.procs_priv` table.

```
GRANT CREATE ROUTINE ON mydb.* TO 'someuser'@'somehost';
GRANT EXECUTE ON PROCEDURE mydb.myproc TO 'someuser'@'somehost';
```

The *object_type* clause should be specified as `TABLE`, `FUNCTION`, or `PROCEDURE` when the following object is a table, a stored function, or a stored procedure.

For the `GRANT` and `REVOKE` statements, *priv_type* can be specified as any of the following:

Privilege	Meaning
<code>ALL [PRIVILEGES]</code>	Sets all simple privileges except <code>GRANT OPTION</code>
<code>ALTER</code>	Enables use of <code>ALTER TABLE</code>
<code>ALTER ROUTINE</code>	Enables stored routines to be altered or dropped
<code>CREATE</code>	Enables use of <code>CREATE TABLE</code>
<code>CREATE ROUTINE</code>	Enables creation of stored routines
<code>CREATE TEMPORARY TABLES</code>	Enables use of <code>CREATE TEMPORARY TABLE</code>
<code>CREATE USER</code>	Enables use of <code>CREATE USER</code> , <code>DROP USER</code> , <code>RENAME USER</code> , and <code>REVOKE ALL PRIVILEGES</code> .
<code>CREATE VIEW</code>	Enables use of <code>CREATE VIEW</code>
<code>DELETE</code>	Enables use of <code>DELETE</code>
<code>DROP</code>	Enables use of <code>DROP TABLE</code>
<code>EVENT</code>	Enables creation of events for the event scheduler

EXECUTE	Enables the user to run stored routines
FILE	Enables use of <code>SELECT ... INTO OUTFILE</code> and <code>LOAD DATA INFILE</code>
INDEX	Enables use of <code>CREATE INDEX</code> and <code>DROP INDEX</code>
INSERT	Enables use of <code>INSERT</code>
LOCK TABLES	Enables use of <code>LOCK TABLES</code> on tables for which you have the <code>SELECT</code> privilege
PROCESS	Enables the user to see all processes with <code>SHOW PROCESSLIST</code>
REFERENCES	Not implemented
RELOAD	Enables use of <code>FLUSH</code>
REPLICATION CLIENT	Enables the user to ask where slave or master servers are
REPLICATION SLAVE	Needed for replication slaves (to read binary log events from the master)
SELECT	Enables use of <code>SELECT</code>
SHOW DATABASES	<code>SHOW DATABASES</code> shows all databases
SHOW VIEW	Enables use of <code>SHOW CREATE VIEW</code>
SHUTDOWN	Enables use of <code>mysqladmin shutdown</code>
SUPER	Enables use of <code>CHANGE MASTER</code> , <code>KILL</code> , <code>PURGE MASTER LOGS</code> , and <code>SET GLOBAL</code> statements, the <code>mysqladmin debug</code> command; allows you to connect (once) even if <code>max_connections</code> is reached
TRIGGER	Enables the user to create or drop triggers
UPDATE	Enables use of <code>UPDATE</code>
USAGE	Synonym for “no privileges”
GRANT OPTION	Enables privileges to be granted

The `EVENT` and `TRIGGER` privileges were added in MySQL 5.1.6. A trigger is associated with a table, so to create or drop a trigger, you must have the `TRIGGER` privilege for the table, not the trigger. (Before MySQL 5.1.6, the `SUPER` privilege was required to create or drop triggers.)

The `REFERENCES` privilege currently is unused.

`USAGE` can be specified when you want to create a user that has no privileges.

Use `SHOW GRANTS` to determine what privileges an account has. See [Section 12.5.4.17, “SHOW GRANTS Syntax”](#).

You can assign global privileges by using `ON *.*` syntax or database-level privileges by using `ON db_name.*` syntax. If you specify `ON *` and you have selected a default database, the privileges are granted in that database.

Warning

If you specify `ON *` and you have *not* selected a default database, the privileges granted are global.

The `FILE`, `PROCESS`, `RELOAD`, `REPLICATION CLIENT`, `REPLICATION SLAVE`, `SHOW DATABASES`, `SHUTDOWN`, `SUPER`, and `CREATE USER` privileges are administrative privileges that can only be granted globally (using `ON *.*` syntax).

Other privileges can be granted globally or at more specific levels.

The *priv_type* values that you can specify for a table are `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `CREATE`, `DROP`, `GRANT OPTION`, `INDEX`, `ALTER`, `CREATE VIEW`, `SHOW VIEW` and `TRIGGER`.

The *priv_type* values that you can specify for a column (that is, when you use a *column_list* clause) are `SELECT`, `INSERT`, and `UPDATE`.

The *priv_type* values that you can specify at the routine level are `ALTER ROUTINE`, `EXECUTE`, and `GRANT OPTION`. `CREATE ROUTINE` is not a routine-level privilege because you must have this privilege to create a routine in the first place.

For the global, database, table, and routine levels, `GRANT ALL` assigns only the privileges that exist at the level you are granting. For example, `GRANT ALL ON db_name.*` is a database-level statement, so it does not grant any global-only privileges such as `FILE`.

MySQL allows you to grant privileges even on database objects that do not exist. In such cases, the privileges to be granted must include the [CREATE](#) privilege. *This behavior is by design*, and is intended to enable the database administrator to prepare user accounts and privileges for database objects that are to be created at a later time.

Important

MySQL does not automatically revoke any privileges when you drop a table or database. However, if you drop a routine, any routine-level privileges granted for that routine are revoked.

Note

The `'_'` and `'%'` wildcards are allowed when specifying database names in [GRANT](#) statements that grant privileges at the global or database levels. This means, for example, that if you want to use a `'_'` character as part of a database name, you should specify it as `'\_'` in the [GRANT](#) statement, to prevent the user from being able to access additional databases matching the wildcard pattern; for example, [GRANT ... ON `foo\\\_bar`.* TO ...](#).

To accommodate granting rights to users from arbitrary hosts, MySQL supports specifying the *user* value in the form *user_name@host_name*. If a *user_name* or *host_name* value is legal as an unquoted identifier, you need not quote it. However, quotes are necessary to specify a *user_name* string containing special characters (such as `'-'`), or a *host_name* string containing special characters or wildcard characters (such as `'%'`); for example, `'test-user'@'test-hostname'`. Quote the username and hostname separately.

You can specify wildcards in the hostname. For example, *user_name@'%.loc.gov'* applies to *user_name* for any host in the `loc.gov` domain, and *user_name@'144.155.166.%'* applies to *user_name* for any host in the `144.155.166` class C subnet.

The simple form *user_name* is a synonym for *user_name@'%'*.

MySQL does not support wildcards in usernames. Anonymous users are defined by inserting entries with `User=''` into the `mysql.user` table or by creating a user with an empty name with the [GRANT](#) statement:

```
GRANT ALL ON test.* TO ''@'localhost' ...
```

When specifying quoted values, quote database, table, column, and routine names as identifiers, using backticks (```). Quote hostnames, usernames, and passwords as strings, using single quotes (`'`).

Warning

If you allow anonymous users to connect to the MySQL server, you should also grant privileges to all local users as *user_name@localhost*. Otherwise, the anonymous user account for `localhost` in the `mysql.user` table (created during MySQL installation) is used when named users try to log in to the MySQL server from the local machine. For details, see [Section 5.7.5, “Access Control, Stage 1: Connection Verification”](#).

You can determine whether this applies to you by executing the following query, which lists any anonymous users:

```
SELECT Host, User FROM mysql.user WHERE User='';
```

If you want to delete the local anonymous user account to avoid the problem just described, use these statements:

```
DELETE FROM mysql.user WHERE Host='localhost' AND User='';
FLUSH PRIVILEGES;
```

[GRANT](#) supports hostnames up to 60 characters long. Database, table, column, and routine names can be up to 64 characters. Usernames can be up to 16 characters.

Note

The allowable length for usernames cannot be changed by altering the `mysql.user` table, and attempting to do so results in unpredictable behavior which may even make it impossible for users to log in to the MySQL server. You should never alter any of the tables in the `mysql` database in any manner whatsoever except by means of the procedure prescribed by MySQL AB that is described in [Section 5.5.7, “mysql_upgrade — Check Tables for MySQL Upgrade”](#).

The privileges for a table, column, or routine are formed additively as the logical **OR** of the privileges at each of the privilege levels. For example, if the `mysql.user` table specifies that a user has a global [SELECT](#) privilege, the privilege cannot be denied by an entry at

the database, table, or column level.

The privileges for a column can be calculated as follows:

```
global privileges
OR (database privileges AND host privileges)
OR table privileges
OR column privileges
OR routine privileges
```

In most cases, you grant rights to a user at only one of the privilege levels, so life is not normally this complicated. The details of the privilege-checking procedure are presented in [Section 5.7, “The MySQL Access Privilege System”](#).

If you grant privileges for a username/hostname combination that does not exist in the `mysql.user` table, an entry is added and remains there until deleted with a `DELETE` statement. In other words, `GRANT` may create `user` table entries, but `REVOKE` does not remove them; you must do that explicitly using `DROP USER` or `DELETE`.

Warning

If you create a new user but do not specify an `IDENTIFIED BY` clause, the user has no password. This is very insecure. However, you can enable the `NO_AUTO_CREATE_USER` SQL mode to prevent `GRANT` from creating a new user if it would otherwise do so, unless `IDENTIFIED BY` is given to provide the new user a non-empty password.

MySQL Enterprise

The MySQL Enterprise Monitor specifically guards against user accounts with no passwords. To find out more see <http://www.mysql.com/products/enterprise/advisors.html>.

If a new user is created or if you have global grant privileges, the user's password is set to the password specified by the `IDENTIFIED BY` clause, if one is given. If the user already had a password, this is replaced by the new one.

Passwords can also be set with the `SET PASSWORD` statement. See [Section 12.5.1.6, “SET PASSWORD Syntax”](#).

In the `IDENTIFIED BY` clause, the password should be given as the literal password value. It is unnecessary to use the `PASSWORD( )` function as it is for the `SET PASSWORD` statement. For example:

```
GRANT ... IDENTIFIED BY 'mypass';
```

If you do not want to send the password in clear text and you know the hashed value that `PASSWORD( )` would return for the password, you can specify the hashed value preceded by the keyword `PASSWORD`:

```
GRANT ...
IDENTIFIED BY PASSWORD '*6C8989366EAF75BB670AD8EA7A7FC1176A95CEF4';
```

In a C program, you can get the hashed value by using the `make_scrambled_password( )` C API function.

If you grant privileges for a database, an entry in the `mysql.db` table is created if needed. If all privileges for the database are removed with `REVOKE`, this entry is deleted.

The `SHOW DATABASES` privilege enables the account to see database names by issuing the `SHOW DATABASE` statement. Accounts that do not have this privilege see only databases for which they have some privileges, and cannot use the statement at all if the server was started with the `--skip-show-database` option.

MySQL Enterprise

The `SHOW DATABASES` privilege should be granted only to users who need to see all the databases on a MySQL server. Subscribers to the MySQL Enterprise Monitor are alerted when servers are started without the `--skip-show-database` option. For more information see, <http://www.mysql.com/products/enterprise/advisors.html>.

If a user has no privileges for a table, the table name is not displayed when the user requests a list of tables (for example, with a `SHOW TABLES` statement).

The `WITH GRANT OPTION` clause gives the user the ability to give to other users any privileges the user has at the specified privilege level. You should be careful to whom you give the `GRANT OPTION` privilege, because two users with different privileges may be able to join privileges!

You cannot grant another user a privilege which you yourself do not have; the `GRANT OPTION` privilege enables you to assign only

those privileges which you yourself possess.

Be aware that when you grant a user the **GRANT OPTION** privilege at a particular privilege level, any privileges the user possesses (or may be given in the future) at that level can also be granted by that user to other users. Suppose that you grant a user the **INSERT** privilege on a database. If you then grant the **SELECT** privilege on the database and specify **WITH GRANT OPTION**, that user can give to other users not only the **SELECT** privilege, but also **INSERT**. If you then grant the **UPDATE** privilege to the user on the database, the user can grant **INSERT**, **SELECT**, and **UPDATE**.

For a non-administrative user, you should not grant the **ALTER** privilege globally or for the **mysql** database. If you do that, the user can try to subvert the privilege system by renaming tables!

The **MAX_QUERIES_PER_HOUR count**, **MAX_UPDATES_PER_HOUR count**, and **MAX_CONNECTIONS_PER_HOUR count** options limit the number of queries, updates, and logins a user can perform during any given one-hour period. (Queries for which results are served from the query cache do not count against the **MAX_QUERIES_PER_HOUR** limit.) If **count** is 0 (the default), this means that there is no limitation for that user.

The **MAX_USER_CONNECTIONS count** option limits the maximum number of simultaneous connections that the account can make. If **count** is 0 (the default), the **max_user_connections** system variable determines the number of simultaneous connections for the account.

Note: To specify any of these resource-limit options for an existing user without affecting existing privileges, use **GRANT USAGE ON *.* ... WITH MAX_...**

See [Section 5.8.4, “Limiting Account Resources”](#).

MySQL can check X509 certificate attributes in addition to the usual authentication that is based on the username and password. To specify SSL-related options for a MySQL account, use the **REQUIRE** clause of the **GRANT** statement. (For background information on the use of SSL with MySQL, see [Section 5.8.7, “Using Secure Connections”](#).)

There are a number of different possibilities for limiting connection types for a given account:

- **REQUIRE NONE** indicates that the account has no SSL or X509 requirements. This is the default if no SSL-related **REQUIRE** options are specified. Unencrypted connections are allowed if the username and password are valid. However, encrypted connections can also be used, at the client's option, if the client has the proper certificate and key files. That is, the client need not specify any SSL command options, in which case the connection will be unencrypted. To use an encrypted connection, the client must specify either the **--ssl-ca** option, or all three of the **--ssl-ca**, **--ssl-key**, and **--ssl-cert** options.
- The **REQUIRE SSL** option tells the server to allow only SSL-encrypted connections for the account.

```
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  IDENTIFIED BY 'goodsecret' REQUIRE SSL;
```

To connect, the client must specify the **--ssl-ca** option, and may additionally specify the **--ssl-key** and **--ssl-cert** options.

- **REQUIRE X509** means that the client must have a valid certificate but that the exact certificate, issuer, and subject do not matter. The only requirement is that it should be possible to verify its signature with one of the CA certificates.

```
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  IDENTIFIED BY 'goodsecret' REQUIRE X509;
```

To connect, the client must specify the **--ssl-ca**, **--ssl-key**, and **--ssl-cert** options. This is also true for **ISSUER** and **SUBJECT** because those **REQUIRE** options imply **X509**.

- **REQUIRE ISSUER 'issuer'** places the restriction on connection attempts that the client must present a valid X509 certificate issued by CA **'issuer'**. If the client presents a certificate that is valid but has a different issuer, the server rejects the connection. Use of X509 certificates always implies encryption, so the **SSL** option is unnecessary in this case.

```
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  IDENTIFIED BY 'goodsecret'
  REQUIRE ISSUER '/C=FI/ST=Some-State/L=Helsinki/
    O=MySQL Finland AB/CN=Tonu Samuel/Email=tonu@example.com';
```

Note that the **'issuer'** value should be entered as a single string.

- **REQUIRE SUBJECT 'subject'** places the restriction on connection attempts that the client must present a valid X509 certifi-

ate containing the subject *subject*. If the client presents a certificate that is valid but has a different subject, the server rejects the connection.

```
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  IDENTIFIED BY 'goodsecret'
  REQUIRE SUBJECT '/C=EE/ST=Some-State/L=Tallinn/
    O=MySQL demo client certificate/
    CN=Tonu Samuel/Email=tonu@example.com';
```

Note that the '*subject*' value should be entered as a single string.

- **REQUIRE CIPHER** '*cipher*' is needed to ensure that ciphers and key lengths of sufficient strength are used. SSL itself can be weak if old algorithms using short encryption keys are used. Using this option, you can ask that a specific cipher method is used to allow a connection.

```
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  IDENTIFIED BY 'goodsecret'
  REQUIRE CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

The **SUBJECT**, **ISSUER**, and **CIPHER** options can be combined in the **REQUIRE** clause like this:

```
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  IDENTIFIED BY 'goodsecret'
  REQUIRE SUBJECT '/C=EE/ST=Some-State/L=Tallinn/
    O=MySQL demo client certificate/
    CN=Tonu Samuel/Email=tonu@example.com'
  AND ISSUER '/C=FI/ST=Some-State/L=Helsinki/
    O=MySQL Finland AB/CN=Tonu Samuel/Email=tonu@example.com'
  AND CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

The **AND** keyword is optional between **REQUIRE** options.

The order of the options does not matter, but no option can be specified twice.

When **mysql**d starts, all privileges are read into memory. For details, see [Section 5.7.7, “When Privilege Changes Take Effect”](#).

Note that if you are using table, column, or routine privileges for even one user, the server examines table, column, and routine privileges for all users and this slows down MySQL a bit. Similarly, if you limit the number of queries, updates, or connections for any users, the server must monitor these values.

The biggest differences between the standard SQL and MySQL versions of **GRANT** are:

- In MySQL, privileges are associated with the combination of a hostname and username and not with only a username.
- Standard SQL does not have global or database-level privileges, nor does it support all the privilege types that MySQL supports.
- MySQL does not support the standard SQL **UNDER** privilege.
- Standard SQL privileges are structured in a hierarchical manner. If you remove a user, all privileges the user has been granted are revoked. This is also true in MySQL if you use **DROP USER**. See [Section 12.5.1.2, “DROP USER Syntax”](#).
- In standard SQL, when you drop a table, all privileges for the table are revoked. In standard SQL, when you revoke a privilege, all privileges that were granted based on that privilege are also revoked. In MySQL, privileges can be dropped only with explicit **REVOKE** statements or by manipulating values stored in the MySQL grant tables.
- In MySQL, it is possible to have the **INSERT** privilege for only some of the columns in a table. In this case, you can still execute **INSERT** statements on the table, provided that you omit those columns for which you do not have the **INSERT** privilege. The omitted columns are set to their implicit default values if strict SQL mode is not enabled. In strict mode, the statement is rejected if any of the omitted columns have no default value. (Standard SQL requires you to have the **INSERT** privilege on all columns.) [Section 5.2.6, “SQL Modes”](#), discusses strict mode. [Section 10.1.4, “Data Type Default Values”](#), discusses implicit default values.

12.5.1.4. RENAME USER Syntax

```
RENAME USER old_user TO new_user
[, old_user TO new_user] ...
```

The **RENAME USER** statement renames existing MySQL accounts. To use it, you must have the global **CREATE USER** privilege or the **UPDATE** privilege for the **mysql** database. An error occurs if any old account does not exist or any new account exists. Each account is named using the same format as for the **GRANT** statement; for example, **'jeffrey'@'localhost'**. If you specify only the user-name part of the account name, a hostname part of **'%'** is used. For additional information about specifying account names, see [Section 12.5.1.3, “GRANT Syntax”](#).

RENAME USER does not automatically migrate any database objects that the user created, nor does it migrate any privileges that the user had prior to the renaming. This applies to tables, views, stored routines, triggers, and events.

12.5.1.5. REVOKE Syntax

```
REVOKE priv_type [(column_list)] [, priv_type [(column_list)]] ...
ON [object_type] {tbl_name | * | *.* | db_name.*}
FROM user [, user] ...

REVOKE ALL PRIVILEGES, GRANT OPTION FROM user [, user] ...
```

The **REVOKE** statement enables system administrators to revoke privileges from MySQL accounts. To use **REVOKE**, you must have the **GRANT OPTION** privilege, and you must have the privileges that you are revoking.

Each account is named using the same format as for the **GRANT** statement; for example, **'jeffrey'@'localhost'**. If you specify only the username part of the account name, a hostname part of **'%'** is used. For additional information about specifying account names, see [Section 12.5.1.3, “GRANT Syntax”](#).

For details on the levels at which privileges exist, the allowable **priv_type** values, and the syntax for specifying users and passwords, see [Section 12.5.1.3, “GRANT Syntax”](#).

If the grant tables hold privilege rows that contain mixed-case database or table names and the **lower_case_table_names** system variable is set to a non-zero value, **REVOKE** cannot be used to revoke these privileges. It will be necessary to manipulate the grant tables directly. (**GRANT** will not create such rows when **lower_case_table_names** is set, but such rows might have been created prior to setting the variable.)

To revoke all privileges, use the following syntax, which drops all global, database-, table-, and column-level privileges for the named user or users:

```
REVOKE ALL PRIVILEGES, GRANT OPTION FROM user [, user] ...
```

To use this **REVOKE** syntax, you must have the global **CREATE USER** privilege or the **UPDATE** privilege for the **mysql** database.

REVOKE removes privileges, but does not drop **user** table entries. You must do that explicitly using **DELETE** or **DROP USER** (see [Section 12.5.1.2, “DROP USER Syntax”](#)).

12.5.1.6. SET PASSWORD Syntax

```
SET PASSWORD [FOR user] = PASSWORD('some password')
```

The **SET PASSWORD** statement assigns a password to an existing MySQL user account.

With no **FOR** clause, this statement sets the password for the current user. Any client that has connected to the server using a non-anonymous account can change the password for that account.

With a **FOR** clause, this statement sets the password for a specific account on the current server host. Only clients that have the **UPDATE** privilege for the **mysql** database can do this. The **user** value should be given in **user_name@host_name** format, where **user_name** and **host_name** are exactly as they are listed in the **User** and **Host** columns of the **mysql.user** table entry. For example, if you had an entry with **User** and **Host** column values of **'bob'** and **'%.loc.gov'**, you would write the statement like this:

```
SET PASSWORD FOR 'bob'@'%.loc.gov' = PASSWORD('newpass');
```

That is equivalent to the following statements:

```
UPDATE mysql.user SET Password=PASSWORD('newpass')
WHERE User='bob' AND Host='%.loc.gov';
FLUSH PRIVILEGES;
```

Note

If you are connecting to a MySQL 4.1 or later server using a pre-4.1 client program, do not use the preceding `SET PASSWORD` or `UPDATE` statement without reading [Section 5.7.9, “Password Hashing as of MySQL 4.1”](#), first. The password format changed in MySQL 4.1, and under certain circumstances it is possible that if you change your password, you might not be able to connect to the server afterward.

You can see which account the server authenticated you as by executing `SELECT CURRENT_USER()`.

MySQL Enterprise

For automated notification of users without passwords, subscribe to the MySQL Enterprise Monitor. For more information see <http://www.mysql.com/products/enterprise/advisors.html>.

12.5.2. Table Maintenance Statements

12.5.2.1. ANALYZE TABLE Syntax

```
ANALYZE [LOCAL | NO_WRITE_TO_BINLOG] TABLE tbl_name [, tbl_name] ...
```

`ANALYZE TABLE` analyzes and stores the key distribution for a table. During the analysis, the table is locked with a read lock for `MyISAM`. For `InnoDB` the table is locked with a write lock. This statement works with `MyISAM`, and `InnoDB` tables. For `MyISAM` tables, this statement is equivalent to using `myisamchk --analyze`.

For more information on how the analysis works within `InnoDB`, see [Section 13.5.16, “Restrictions on InnoDB Tables”](#).

MySQL Enterprise

For expert advice on optimizing tables subscribe to the MySQL Enterprise Monitor. For more information see <http://www.mysql.com/products/enterprise/advisors.html>.

MySQL uses the stored key distribution to decide the order in which tables should be joined when you perform a join on something other than a constant.

This statement requires `SELECT` and `INSERT` privileges for the table.

`ANALYZE TABLE` returns a result set with the following columns:

Column	Value
Table	The table name
Op	Always <code>analyze</code>
Msg_type	One of <code>status</code> , <code>error</code> , <code>info</code> , or <code>warning</code>
Msg_text	The message

You can check the stored key distribution with the `SHOW INDEX` statement. See [Section 12.5.4.18, “SHOW INDEX Syntax”](#).

If the table has not changed since the last `ANALYZE TABLE` statement, the table is not analyzed again.

By default, `ANALYZE TABLE` statements are written to the binary log so that such statements used on a MySQL server acting as a replication master will be replicated to replication slaves. Logging can be suppressed with the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

12.5.2.2. BACKUP TABLE Syntax

```
BACKUP TABLE tbl_name [, tbl_name] ... TO '/path/to/backup/directory'
```

Note

This statement is deprecated. We are working on a better replacement for it that will provide online backup capabilities. In the meantime, the `mysqlhotcopy` script can be used instead.

`BACKUP TABLE` copies to the backup directory the minimum number of table files needed to restore the table, after flushing any buf-

ferred changes to disk. The statement works only for **MyISAM** tables. It copies the `.frm` definition and `.MYD` data files. The `.MYI` index file can be rebuilt from those two files. The directory should be specified as a full pathname. To restore the table, use **RESTORE TABLE**.

During the backup, a read lock is held for each table, one at time, as they are being backed up. If you want to back up several tables as a snapshot (preventing any of them from being changed during the backup operation), issue a **LOCK TABLES** statement first, to obtain a read lock for all tables in the group.

BACKUP TABLE returns a result set with the following columns:

Column	Value
Table	The table name
Op	Always backup
Msg_type	One of status , error , info , or warning
Msg_text	The message

12.5.2.3. CHECK TABLE Syntax

```
CHECK TABLE tbl_name [, tbl_name] ... [option] ...
option = {FOR UPGRADE | QUICK | FAST | MEDIUM | EXTENDED | CHANGED}
```

CHECK TABLE checks a table or tables for errors. **CHECK TABLE** works for **MyISAM**, **InnoDB**, and **ARCHIVE** tables. Starting with MySQL 5.1.9, **CHECK** is also valid for **CSV** tables, see [Section 13.11, “The CSV Storage Engine”](#). For **MyISAM** tables, the key statistics are updated as well.

CHECK TABLE can also check views for problems, such as tables that are referenced in the view definition that no longer exist.

CHECK TABLE returns a result set with the following columns:

Column	Value
Table	The table name
Op	Always check
Msg_type	One of status , error , info , or warning
Msg_text	The message

Note that the statement might produce many rows of information for each checked table. The last row has a **Msg_type** value of **status** and the **Msg_text** normally should be **OK**. If you don't get **OK**, or **Table is already up to date** you should normally run a repair of the table. See [Section 5.9.4, “Table Maintenance and Crash Recovery”](#). **Table is already up to date** means that the storage engine for the table indicated that there was no need to check the table.

The **FOR UPGRADE** option checks whether the named tables are compatible with the current version of MySQL. This option was added in MySQL 5.1.7. With **FOR UPGRADE**, the server checks each table to determine whether there have been any incompatible changes in any of the table's data types or indexes since the table was created. If not, the check succeeds. Otherwise, if there is a possible incompatibility, the server runs a full check on the table (which might take some time). If the full check succeeds, the server marks the table's `.frm` file with the current MySQL version number. Marking the `.frm` file ensures that further checks for the table with the same version of the server will be fast.

Incompatibilities might occur because the storage format for a data type has changed or because its sort order has changed. Our aim is to avoid these changes, but occasionally they are necessary to correct problems that would be worse than an incompatibility between releases.

Currently, **FOR UPGRADE** discovers these incompatibilities:

- The indexing order for end-space in **TEXT** columns for **InnoDB** and **MyISAM** tables changed between MySQL 4.1 and 5.0.
- The storage method of the new **DECIMAL** data type changed between MySQL 5.0.3 and 5.0.5.

The other check options that can be given are shown in the following table. These options apply only to checking **MyISAM** tables and are ignored for **InnoDB** tables and views.

Type	Meaning
QUICK	Do not scan the rows to check for incorrect links.
FAST	Check only tables that have not been closed properly.
CHANGED	Check only tables that have been changed since the last check or that have not been closed properly.
MEDIUM	Scan rows to verify that deleted links are valid. This also calculates a key checksum for the rows and verifies this with a calculated checksum for the keys.
EXTENDED	Do a full key lookup for all keys for each row. This ensures that the table is 100% consistent, but takes a long time.

If none of the options **QUICK**, **MEDIUM**, or **EXTENDED** are specified, the default check type for dynamic-format **MyISAM** tables is **MEDIUM**. This has the same result as running `myisamchk --medium-check tbl_name` on the table. The default check type also is **MEDIUM** for static-format **MyISAM** tables, unless **CHANGED** or **FAST** is specified. In that case, the default is **QUICK**. The row scan is skipped for **CHANGED** and **FAST** because the rows are very seldom corrupted.

You can combine check options, as in the following example that does a quick check on the table to determine whether it was closed properly:

```
CHECK TABLE test_table FAST QUICK;
```

Note

In some cases, **CHECK TABLE** changes the table. This happens if the table is marked as “corrupted” or “not closed properly” but **CHECK TABLE** does not find any problems in the table. In this case, **CHECK TABLE** marks the table as okay.

If a table is corrupted, it is most likely that the problem is in the indexes and not in the data part. All of the preceding check types check the indexes thoroughly and should thus find most errors.

If you just want to check a table that you assume is okay, you should use no check options or the **QUICK** option. The latter should be used when you are in a hurry and can take the very small risk that **QUICK** does not find an error in the data file. (In most cases, under normal usage, MySQL should find any error in the data file. If this happens, the table is marked as “corrupted” and cannot be used until it is repaired.)

FAST and **CHANGED** are mostly intended to be used from a script (for example, to be executed from **cron**) if you want to check tables from time to time. In most cases, **FAST** is to be preferred over **CHANGED**. (The only case when it is not preferred is when you suspect that you have found a bug in the **MyISAM** code.)

EXTENDED is to be used only after you have run a normal check but still get strange errors from a table when MySQL tries to update a row or find a row by key. This is very unlikely if a normal check has succeeded.

Use of **CHECK TABLE ... EXTENDED** might influence the execution plan generated by the query optimizer.

Some problems reported by **CHECK TABLE** cannot be corrected automatically:

- **Found row where the auto_increment column has the value 0.**

This means that you have a row in the table where the **AUTO_INCREMENT** index column contains the value 0. (It is possible to create a row where the **AUTO_INCREMENT** column is 0 by explicitly setting the column to 0 with an **UPDATE** statement.)

This is not an error in itself, but could cause trouble if you decide to dump the table and restore it or do an **ALTER TABLE** on the table. In this case, the **AUTO_INCREMENT** column changes value according to the rules of **AUTO_INCREMENT** columns, which could cause problems such as a duplicate-key error.

To get rid of the warning, simply execute an **UPDATE** statement to set the column to some value other than 0.

- If **CHECK TABLE** finds a problem for an **InnoDB** table, the server shuts down to prevent error propagation. Details of the error will be written to the error log.

12.5.2.4. CHECKSUM TABLE Syntax

```
CHECKSUM TABLE tbl_name [, tbl_name] ... [ QUICK | EXTENDED ]
```

CHECKSUM TABLE reports a table checksum.

With **QUICK**, the live table checksum is reported if it is available, or **NULL** otherwise. This is very fast. A live checksum is enabled by specifying the **CHECKSUM=1** table option when you create the table; currently, this is supported only for **MyISAM** tables. See [Section 12.1.10, “CREATE TABLE Syntax”](#).

With **EXTENDED**, the entire table is read row by row and the checksum is calculated. This can be very slow for large tables.

If neither **QUICK** nor **EXTENDED** is specified, MySQL returns a live checksum if the table storage engine supports it and scans the table otherwise.

For a non-existent table, **CHECKSUM TABLE** returns **NULL** and generates a warning.

The checksum value depends on the table row format. If the row format changes, the checksum also changes. For example, the storage format for **VARCHAR** changed between MySQL 4.1 and 5.0, so if a 4.1 table is upgraded to MySQL 5.0, the checksum value may change.

12.5.2.5. OPTIMIZE TABLE Syntax

```
OPTIMIZE [LOCAL | NO_WRITE_TO_BINLOG] TABLE tbl_name [, tbl_name] ...
```

OPTIMIZE TABLE should be used if you have deleted a large part of a table or if you have made many changes to a table with variable-length rows (tables that have **VARCHAR**, **VARBINARY**, **BLOB**, or **TEXT** columns). Deleted rows are maintained in a linked list and subsequent **INSERT** operations reuse old row positions. You can use **OPTIMIZE TABLE** to reclaim the unused space and to defragment the data file.

This statement requires **SELECT** and **INSERT** privileges for the table.

In most setups, you need not run **OPTIMIZE TABLE** at all. Even if you do a lot of updates to variable-length rows, it is not likely that you need to do this more than once a week or month and only on certain tables.

OPTIMIZE TABLE works *only* for **MyISAM**, **InnoDB**, and **ARCHIVE** tables. It does *not* work for tables created using any other storage engine, including **NDB** Disk Data tables.

For **MyISAM** tables, **OPTIMIZE TABLE** works as follows:

1. If the table has deleted or split rows, repair the table.
2. If the index pages are not sorted, sort them.
3. If the table's statistics are not up to date (and the repair could not be accomplished by sorting the index), update them.

For **InnoDB** tables, **OPTIMIZE TABLE** is mapped to **ALTER TABLE**, which rebuilds the table to update index statistics and free unused space in the clustered index.

You can make **OPTIMIZE TABLE** work on other storage engines by starting **mysqld** with the **--skip-new** or **--safe-mode** option. In this case, **OPTIMIZE TABLE** is just mapped to **ALTER TABLE**.

OPTIMIZE TABLE returns a result set with the following columns:

Column	Value
Table	The table name
Op	Always optimize
Msg_type	One of status , error , info , or warning
Msg_text	The message

Note that MySQL locks the table during the time **OPTIMIZE TABLE** is running.

By default, **OPTIMIZE TABLE** statements are written to the binary log so that such statements used on a MySQL server acting as a replication master will be replicated to replication slaves. Logging can be suppressed with the optional **NO_WRITE_TO_BINLOG** keyword or its alias **LOCAL**.

OPTIMIZE TABLE does not sort R-tree indexes, such as spatial indexes on **POINT** columns. (Bug#23578)

12.5.2.6. REPAIR TABLE Syntax

```
REPAIR [LOCAL | NO_WRITE_TO_BINLOG] TABLE
      tbl_name [, tbl_name] ... [QUICK] [EXTENDED] [USE_FRM]
```

REPAIR TABLE repairs a possibly corrupted table. By default, it has the same effect as `myisamchk --recover tbl_name`. **REPAIR TABLE** works for **MyISAM** and for **ARCHIVE** tables. Starting with MySQL 5.1.9, **REPAIR** is also valid for **CSV** tables. See Section 13.4, “The MyISAM Storage Engine”, and Section 13.10, “The ARCHIVE Storage Engine”, and Section 13.11, “The CSV Storage Engine”

This statement requires **SELECT** and **INSERT** privileges for the table.

Normally, you should never have to run this statement. However, if disaster strikes, **REPAIR TABLE** is very likely to get back all your data from a **MyISAM** table. If your tables become corrupted often, you should try to find the reason for it, to eliminate the need to use **REPAIR TABLE**. See Section B.1.4.2, “What to Do If MySQL Keeps Crashing”, and Section 13.4.4, “MyISAM Table Problems”.

Caution

It is best to make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to filesystem errors.

Warning

If the server dies during a **REPAIR TABLE** operation, it is essential after restarting it that you immediately execute another **REPAIR TABLE** statement for the table before performing any other operations on it. (It is always a good idea to start by making a backup.) In the worst case, you might have a new clean index file without information about the data file, and then the next operation you perform could overwrite the data file. This is an unlikely but possible scenario.

REPAIR TABLE returns a result set with the following columns:

Column	Value
Table	The table name
Op	Always repair
Msg_type	One of status , error , info , or warning
Msg_text	The message

The **REPAIR TABLE** statement might produce many rows of information for each repaired table. The last row has a **Msg_type** value of **status** and **Msg_text** normally should be **OK**. If you do not get **OK**, you should try repairing the table with `myisamchk -safe-recover`. (**REPAIR TABLE** does not yet implement all the options of `myisamchk`.) With `myisamchk -safe-recover`, you can also use options that **REPAIR TABLE** does not support, such as `--max-record-length`.

If **QUICK** is given, **REPAIR TABLE** tries to repair only the index tree. This type of repair is like that done by `myisamchk -recover --quick`.

If you use **EXTENDED**, MySQL creates the index row by row instead of creating one index at a time with sorting. This type of repair is like that done by `myisamchk -safe-recover`.

There is also a **USE_FRM** mode available for **REPAIR TABLE**. Use this if the **.MYI** index file is missing or if its header is corrupted. In this mode, MySQL re-creates the **.MYI** file using information from the **.frm** file. This kind of repair cannot be done with `myisamchk`.

Note

Use this mode *only* if you cannot use regular **REPAIR** modes. The **.MYI** header contains important table metadata (in par-

ticular, current [AUTO_INCREMENT](#) value and [Delete link](#)) that are lost in `REPAIR ... USE_FRM`. Don't use `USE_FRM` if the table is compressed because this information is also stored in the `.MYI` file.

Caution

Do not use `USE_FRM` if your table was created by a different version of the MySQL server than the one you are currently running. Doing so risks the loss of all rows in the table. It is particularly dangerous to use `USE_FRM` after the server returns this message:

```
Table upgrade required. Please do
"REPAIR TABLE `tbl_name`" to fix it!
```

By default, `REPAIR TABLE` statements are written to the binary log so that such statements used on a MySQL server acting as a replication master will be replicated to replication slaves. Logging can be suppressed with the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

12.5.2.7. RESTORE TABLE Syntax

```
RESTORE TABLE tbl_name [, tbl_name] ... FROM '/path/to/backup/directory'
```

`RESTORE TABLE` restores the table or tables from a backup that was made with `BACKUP TABLE`. The directory should be specified as a full pathname.

Existing tables are not overwritten; if you try to restore over an existing table, an error occurs. Just as for `BACKUP TABLE`, `RESTORE TABLE` currently works only for `MyISAM` tables. Restored tables are not replicated from master to slave.

The backup for each table consists of its `.frm` format file and `.MYD` data file. The restore operation restores those files, and then uses them to rebuild the `.MYI` index file. Restoring takes longer than backing up due to the need to rebuild the indexes. The more indexes the table has, the longer it takes.

`RESTORE TABLE` returns a result set with the following columns:

Column	Value
Table	The table name
Op	Always <code>restore</code>
Msg_type	One of <code>status</code> , <code>error</code> , <code>info</code> , or <code>warning</code>
Msg_text	The message

12.5.3. SET Syntax

```
SET variable_assignment [, variable_assignment] ...

variable_assignment:
    user_var_name = expr
    | [GLOBAL | SESSION] system_var_name = expr
    | [@@global. | @@session. | @@] system_var_name = expr
```

The `SET` statement assigns values to different types of variables that affect the operation of the server or your client. Older versions of MySQL employed `SET OPTION`, but this syntax is deprecated in favor of `SET` without `OPTION`.

This section describes use of `SET` for assigning values to system variables or user variables. For general information about these types of variables, see [Section 5.2.3, “System Variables”](#), and [Section 8.4, “User-Defined Variables”](#). System variables also can be set at server startup, as described in [Section 5.2.4, “Using System Variables”](#).

Some variants of `SET` syntax are used in other contexts:

- `SET PASSWORD` assigns account passwords. See [Section 12.5.1.6, “SET PASSWORD Syntax”](#).
- `SET TRANSACTION ISOLATION LEVEL` sets the isolation level for transaction processing. See [Section 12.4.6, “SET TRANSACTION Syntax”](#).
- `SET` is used within stored routines to assign values to local routine variables. See [Section 19.2.7.2, “Variable SET Statement”](#).

The following discussion shows the different **SET** syntaxes that you can use to set variables. The examples use the **=** assignment operator, but the **:=** operator also is allowable.

A user variable is written as **@var_name** and can be set as follows:

```
SET @var_name = expr;
```

Many system variables are dynamic and can be changed while the server runs by using the **SET** statement. For a list, see [Section 5.2.4.2, “Dynamic System Variables”](#). To change a system variable with **SET**, refer to it as **var_name**, optionally preceded by a modifier:

- To indicate explicitly that a variable is a global variable, precede its name by **GLOBAL** or **@@global..** The **SUPER** privilege is required to set global variables.
- To indicate explicitly that a variable is a session variable, precede its name by **SESSION**, **@@session.**, or **@@**. Setting a session variable requires no special privilege, but a client can change only its own session variables, not those of any other client.
- **LOCAL** and **@@local.** are synonyms for **SESSION** and **@@session..**
- If no modifier is present, **SET** changes the session variable.

MySQL Enterprise

The MySQL Enterprise Monitor makes extensive use of system variables to determine the state of your server. For more information see <http://www.mysql.com/products/enterprise/advisors.html>.

A **SET** statement can contain multiple variable assignments, separated by commas. If you set several system variables, the most recent **GLOBAL** or **SESSION** modifier in the statement is used for following variables that have no modifier specified.

Examples:

```
SET sort_buffer_size=10000;
SET @@local.sort_buffer_size=10000;
SET GLOBAL sort_buffer_size=1000000, SESSION sort_buffer_size=1000000;
SET @@sort_buffer_size=1000000;
SET @@global.sort_buffer_size=1000000, @@local.sort_buffer_size=1000000;
```

When you assign a value to a system variable with **SET**, you cannot use suffix letters in the value (as can be done with startup options). However, the value can take the form of an expression:

```
SET sort_buffer_size = 10 * 1024 * 1024;
```

The **@@var_name** syntax for system variables is supported for compatibility with some other database systems.

If you change a session system variable, the value remains in effect until your session ends or until you change the variable to a different value. The change is not visible to other clients.

If you change a global system variable, the value is remembered and used for new connections until the server restarts. (To make a global system variable setting permanent, you should set it in an option file.) The change is visible to any client that accesses that global variable. However, the change affects the corresponding session variable only for clients that connect after the change. The global variable change does not affect the session variable for any client that is currently connected (not even that of the client that issues the **SET GLOBAL** statement).

To prevent incorrect usage, MySQL produces an error if you use **SET GLOBAL** with a variable that can only be used with **SET SESSION** or if you do not specify **GLOBAL** (or **@@global.**) when setting a global variable.

To set a **SESSION** variable to the **GLOBAL** value or a **GLOBAL** value to the compiled-in MySQL default value, use the **DEFAULT** keyword. For example, the following two statements are identical in setting the session value of **max_join_size** to the global value:

```
SET max_join_size=DEFAULT;
SET @@session.max_join_size=@@global.max_join_size;
```

Not all system variables can be set to **DEFAULT**. In such cases, use of **DEFAULT** results in an error.

You can refer to the values of specific global or session system variables in expressions by using one of the @@-modifiers. For example, you can retrieve values in a `SELECT` statement like this:

```
SELECT @@global.sql_mode, @@session.sql_mode, @@sql_mode;
```

When you refer to a system variable in an expression as `@@var_name` (that is, when you do not specify `@@global.` or `@@session.`), MySQL returns the session value if it exists and the global value otherwise. (This differs from `SET @@var_name = value`, which always refers to the session value.)

To display system variables names and values, use the `SHOW VARIABLES` statement. (See [Section 12.5.4.31, “SHOW VARIABLES Syntax”](#).)

The following list describes options that have non-standard syntax or that are not described in the list of system variables found in [Section 5.2.3, “System Variables”](#). Although the options described here are not displayed by `SHOW VARIABLES`, you can obtain their values with `SELECT` (with the exception of `CHARACTER SET` and `SET NAMES`). For example:

```
mysql> SELECT @@AUTOCOMMIT;
+-----+
| @@AUTOCOMMIT |
+-----+
|             1 |
+-----+
```

The lettercase of these options does not matter.

- `AUTOCOMMIT = {0 | 1}`

Set the autocommit mode. If set to 1, all changes to a table take effect immediately. If set to 0 you have to use `COMMIT` to accept a transaction or `ROLLBACK` to cancel it. By default, client connections begin with `AUTOCOMMIT` set to 1. If you change `AUTOCOMMIT` mode from 0 to 1, MySQL performs an automatic `COMMIT` of any open transaction. Another way to begin a transaction is to use a `START TRANSACTION` or `BEGIN` statement. See [Section 12.4.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”](#).

- `BIG_TABLES = {0 | 1}`

If set to 1, all temporary tables are stored on disk rather than in memory. This is a little slower, but the error `The table tbl_name is full` does not occur for `SELECT` operations that require a large temporary table. The default value for a new connection is 0 (use in-memory temporary tables). Normally, you should never need to set this variable, because in-memory tables are automatically converted to disk-based tables as required.

Note

This variable was formerly named `SQL_BIG_TABLES`.

- `CHARACTER SET {charset_name | DEFAULT}`

This maps all strings from and to the client with the given mapping. You can add new mappings by editing `sql/convert.cc` in the MySQL source distribution. `SET CHARACTER SET` sets three session system variables: `character_set_client` and `character_set_results` are set to the given character set, and `character_set_connection` to the value of `character_set_database`. See [Section 9.4, “Connection Character Sets and Collations”](#).

The default mapping can be restored by using the value `DEFAULT`. The default depends on the server configuration.

Note that the syntax for `SET CHARACTER SET` differs from that for setting most other options.

- `FOREIGN_KEY_CHECKS = {0 | 1}`

If set to 1 (the default), foreign key constraints for `InnoDB` tables are checked. If set to 0, they are ignored. Disabling foreign key checking can be useful for reloading `InnoDB` tables in an order different from that required by their parent/child relationships. See [Section 13.5.6.4, “FOREIGN KEY Constraints”](#).

Setting `FOREIGN_KEY_CHECKS` to 0 also affects data definition statements: `DROP SCHEMA` drops a schema even if it contains tables that have foreign keys that are referred to by tables outside the schema, and `DROP TABLE` drops tables that have foreign keys that are referred to by other tables.

Note

Setting `FOREIGN_KEY_CHECKS` to 1 does not trigger a scan of the existing table data. Therefore, rows added to the table while `FOREIGN_KEY_CHECKS=0` will not be verified for consistency.

- `IDENTITY = value`

This variable is a synonym for the `LAST_INSERT_ID` variable. It exists for compatibility with other database systems. You can read its value with `SELECT @@IDENTITY`, and set it using `SET IDENTITY`.

- `INSERT_ID = value`

Set the value to be used by the following `INSERT` or `ALTER TABLE` statement when inserting an `AUTO_INCREMENT` value. This is mainly used with the binary log.

- `LAST_INSERT_ID = value`

Set the value to be returned from `LAST_INSERT_ID()`. This is stored in the binary log when you use `LAST_INSERT_ID()` in a statement that updates a table. Setting this variable does not update the value returned by the `mysql_insert_id()` C API function.

- `NAMES {'charset_name' [COLLATE 'collation_name'] | DEFAULT}`

`SET NAMES` sets the three session system variables `character_set_client`, `character_set_connection`, and `character_set_results` to the given character set. Setting `character_set_connection` to `charset_name` also sets `collation_connection` to the default collation for `charset_name`. The optional `COLLATE` clause may be used to specify a collation explicitly. See [Section 9.4, “Connection Character Sets and Collations”](#).

The default mapping can be restored by using a value of `DEFAULT`. The default depends on the server configuration.

Note that the syntax for `SET NAMES` differs from that for setting most other options.

- `ONE_SHOT`

This option is a modifier, not a variable. It can be used to influence the effect of variables that set the character set, the collation, and the time zone. `ONE_SHOT` is primarily used for replication purposes: `mysqlbinlog` uses `SET ONE_SHOT` to modify temporarily the values of character set, collation, and time zone variables to reflect at rollforward what they were originally. `ONE_SHOT` is for internal use only and is deprecated for MySQL 5.0 and up.

You cannot use `ONE_SHOT` with other than the allowed set of variables; if you try, you get an error like this:

```
mysql> SET ONE_SHOT max_allowed_packet = 1;
ERROR 1382 (HY000): The 'SET ONE_SHOT' syntax is reserved for purposes
internal to the MySQL server
```

If `ONE_SHOT` is used with the allowed variables, it changes the variables as requested, but only for the next non-`SET` statement. After that, the server resets all character set, collation, and time zone-related system variables to their previous values. Example:

```
mysql> SET ONE_SHOT character_set_connection = latin5;
mysql> SET ONE_SHOT collation_connection = latin5_turkish_ci;
mysql> SHOW VARIABLES LIKE '%_connection';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| character_set_connection | latin5 |
| collation_connection | latin5_turkish_ci |
+-----+-----+

mysql> SHOW VARIABLES LIKE '%_connection';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| character_set_connection | latin1 |
| collation_connection | latin1_swedish_ci |
+-----+-----+
```

- `SQL_AUTO_IS_NULL = {0 | 1}`

If set to 1 (the default), you can find the last inserted row for a table that contains an `AUTO_INCREMENT` column by using the following construct:

```
WHERE auto_increment_column IS NULL
```

This behavior is used by some ODBC programs, such as Access.

- `SQL_BIG_SELECTS = {0 | 1}`

If set to 0, MySQL aborts `SELECT` statements that are likely to take a very long time to execute (that is, statements for which the optimizer estimates that the number of examined rows exceeds the value of `max_join_size`). This is useful when an inadvisable `WHERE` statement has been issued. The default value for a new connection is 1, which allows all `SELECT` statements.

If you set the `max_join_size` system variable to a value other than `DEFAULT`, `SQL_BIG_SELECTS` is set to 0.

- `SQL_BUFFER_RESULT = {0 | 1}`

If set to 1, `SQL_BUFFER_RESULT` forces results from `SELECT` statements to be put into temporary tables. This helps MySQL free the table locks early and can be beneficial in cases where it takes a long time to send results to the client. The default value is 0.

- `SQL_LOG_BIN = {0 | 1}`

If set to 0, no logging is done to the binary log for the client. The client must have the `SUPER` privilege to set this option. The default value is 1.

- `SQL_LOG_OFF = {0 | 1}`

If set to 1, no logging is done to the general query log for this client. The client must have the `SUPER` privilege to set this option. The default value is 0.

- `SQL_LOG_UPDATE = {0 | 1}`

This variable is deprecated, and is mapped to `SQL_LOG_BIN`.

- `SQL_NOTES = {0 | 1}`

If set to 1 (the default), warnings of `Note` level are recorded. If set to 0, `Note` warnings are suppressed. `mysqldump` includes output to set this variable to 0 so that reloading the dump file does not produce warnings for events that do not affect the integrity of the reload operation.

- `SQL_QUOTE_SHOW_CREATE = {0 | 1}`

If set to 1 (the default), the server quotes identifiers for `SHOW CREATE TABLE` and `SHOW CREATE DATABASE` statements. If set to 0, quoting is disabled. This option is enabled by default so that replication works for identifiers that require quoting. See [Section 12.5.4.9, “SHOW CREATE TABLE Syntax”](#), and [Section 12.5.4.6, “SHOW CREATE DATABASE Syntax”](#).

- `SQL_SAFE_UPDATES = {0 | 1}`

If set to 1, MySQL aborts `UPDATE` or `DELETE` statements that do not use a key in the `WHERE` clause or a `LIMIT` clause. This makes it possible to catch `UPDATE` or `DELETE` statements where keys are not used properly and that would probably change or delete a large number of rows. The default value is 0.

- `SQL_SELECT_LIMIT = {value | DEFAULT}`

The maximum number of rows to return from `SELECT` statements. The default value for a new connection is “unlimited.” If you have changed the limit, the default value can be restored by using a `SQL_SELECT_LIMIT` value of `DEFAULT`.

If a `SELECT` has a `LIMIT` clause, the `LIMIT` takes precedence over the value of `SQL_SELECT_LIMIT`.

`SQL_SELECT_LIMIT` does not apply to `SELECT` statements executed within stored routines. It also does not apply to `SELECT` statements that do not produce a result set to be returned to the client. These include `SELECT` statements in subqueries, `CREATE TABLE ... SELECT`, and `INSERT INTO ... SELECT`.

- `SQL_WARNINGS = {0 | 1}`

This variable controls whether single-row **INSERT** statements produce an information string if warnings occur. The default is 0. Set the value to 1 to produce an information string.

- **TIMESTAMP** = {*timestamp_value* | DEFAULT}

Set the time for this client. This is used to get the original timestamp if you use the binary log to restore rows. *timestamp_value* should be a Unix epoch timestamp, not a MySQL timestamp.

SET TIMESTAMP affects the value returned by **NOW()** but not by **SYSDATE()**. This means that timestamp settings in the binary log have no effect on invocations of **SYSDATE()**. The server can be started with the **--sysdate-is-now** option to cause **SYS-DATE()** to be an alias for **NOW()**, in which case **SET TIMESTAMP** affects both functions.

- **UNIQUE_CHECKS** = {0 | 1}

If set to 1 (the default), uniqueness checks for secondary indexes in **InnoDB** tables are performed. If set to 0, storage engines are allowed to assume that duplicate keys are not present in input data. If you know for certain that your data does not contain uniqueness violations, you can set this to 0 to speed up large table imports to **InnoDB**.

Note that setting this variable to 0 does not *require* storage engines to ignore duplicate keys. An engine is still allowed to check for them and issue duplicate-key errors if it detects them.

12.5.4. SHOW Syntax

SHOW has many forms that provide information about databases, tables, columns, or status information about the server. This section describes those following:

```
SHOW AUTHORS
SHOW CHARACTER SET [like_or_where]
[like_or_where]
SHOW COLLATION [like_or_where]
SHOW [FULL] COLUMNS FROM tbl_name [FROM db_name] [like_or_where]
SHOW CONTRIBUTORS
SHOW CREATE DATABASE db_name
SHOW CREATE EVENT event_name
SHOW CREATE FUNCTION funcname
SHOW CREATE PROCEDURE procname
SHOW CREATE TABLE tbl_name
SHOW CREATE TRIGGER trigger_name
SHOW CREATE VIEW view_name
SHOW DATABASES [like_or_where]
SHOW ENGINE engine_name {STATUS | MUTEX}
SHOW [STORAGE] ENGINES
SHOW ERRORS [LIMIT [offset,] row_count]
SHOW [FULL] EVENTS
SHOW FUNCTION CODE sp_name
SHOW FUNCTION STATUS [like_or_where]
SHOW GRANTS FOR user
SHOW INDEX FROM tbl_name [FROM db_name]
SHOW INNODB STATUS
SHOW OPEN TABLES [FROM db_name] [like_or_where]
SHOW PROCEDURE CODE sp_name
SHOW PROCEDURE STATUS [like_or_where]
SHOW PLUGINS
SHOW PRIVILEGES
SHOW [FULL] PROCESSLIST
SHOW SCHEDULER STATUS
SHOW [GLOBAL | SESSION] STATUS [like_or_where]
SHOW TABLE STATUS [FROM db_name] [like_or_where]
SHOW TABLES [FROM db_name] [like_or_where]
SHOW TRIGGERS [FROM db_name] [like_or_where]
SHOW [GLOBAL | SESSION] VARIABLES [like_or_where]
SHOW WARNINGS [LIMIT [offset,] row_count]

like_or_where:
    LIKE 'pattern'
    | WHERE expr
```

The **SHOW** statement also has forms that provide information about replication master and slave servers and are described in [Section 12.6, “Replication Statements”](#):

```
SHOW BINARY LOGS
SHOW BINLOG EVENTS
SHOW MASTER STATUS
SHOW SLAVE HOSTS
SHOW SLAVE STATUS
```

If the syntax for a given `SHOW` statement includes a `LIKE 'pattern'` part, `'pattern'` is a string that can contain the SQL `'%'` and `'_'` wildcard characters. The pattern is useful for restricting statement output to matching values.

Several `SHOW` statements also accept a `WHERE` clause that provides more flexibility in specifying which rows to display. See [Section 23.27, “Extensions to SHOW Statements”](#).

Many MySQL APIs (such as PHP) allow you to treat the result returned from a `SHOW` statement as you would a result set from a `SELECT`; see [Chapter 25, APIs and Libraries](#), or your API documentation for more information. In addition, you can work in SQL with results from queries on tables in the `INFORMATION_SCHEMA` database, which you cannot easily do with results from `SHOW` statements. See [Chapter 23, The INFORMATION_SCHEMA Database](#).

12.5.4.1. SHOW AUTHORS Syntax

```
SHOW AUTHORS
```

The `SHOW AUTHORS` statement displays information about the people who work on MySQL. For each author, it displays `Name`, `Location`, and `Comment` values.

This statement was added in MySQL 5.1.3.

12.5.4.2. SHOW CHARACTER SET Syntax

```
SHOW CHARACTER SET
[LIKE 'pattern' | WHERE expr]
```

The `SHOW CHARACTER SET` statement shows all available character sets. The `LIKE` clause, if present, indicates which character set names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 23.27, “Extensions to SHOW Statements”](#). For example:

```
mysql> SHOW CHARACTER SET LIKE 'latin%';
```

Charset	Description	Default collation	Maxlen
latin1	cp1252 West European	latin1_swedish_ci	1
latin2	ISO 8859-2 Central European	latin2_general_ci	1
latin5	ISO 8859-9 Turkish	latin5_turkish_ci	1
latin7	ISO 8859-13 Baltic	latin7_general_ci	1

The `Maxlen` column shows the maximum number of bytes required to store one character.

12.5.4.3. SHOW COLLATION Syntax

```
SHOW COLLATION
[LIKE 'pattern' | WHERE expr]
```

The output from `SHOW COLLATION` includes all available character sets. The `LIKE` clause, if present, indicates which collation names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 23.27, “Extensions to SHOW Statements”](#). For example:

```
mysql> SHOW COLLATION LIKE 'latin1%';
```

Collation	Charset	Id	Default	Compiled	Sortlen
latin1_german1_ci	latin1	5			0
latin1_swedish_ci	latin1	8	Yes	Yes	0
latin1_danish_ci	latin1	15			0
latin1_german2_ci	latin1	31		Yes	2
latin1_bin	latin1	47		Yes	0
latin1_general_ci	latin1	48			0
latin1_general_cs	latin1	49			0
latin1_spanish_ci	latin1	94			0

The `Default` column indicates whether a collation is the default for its character set. `Compiled` indicates whether the character set is compiled into the server. `Sortlen` is related to the amount of memory required to sort strings expressed in the character set.

12.5.4.4. SHOW COLUMNS Syntax

```
SHOW [FULL] COLUMNS FROM tbl_name [FROM db_name]
[LIKE 'pattern' | WHERE expr]
```

SHOW COLUMNS displays information about the columns in a given table. It also works for views. The **LIKE** clause, if present, indicates which column names to match. The **WHERE** clause can be given to select rows using more general conditions, as discussed in [Section 23.27, “Extensions to SHOW Statements”](#).

The **FULL** keyword causes the output to include the privileges you have as well as any per-column comments for each column.

You can use *db_name.tbl_name* as an alternative to the *tbl_name FROM db_name* syntax. In other words, these two statements are equivalent:

```
mysql> SHOW COLUMNS FROM mytable FROM mydb;
mysql> SHOW COLUMNS FROM mydb.mytable;
```

SHOW FIELDS is a synonym for **SHOW COLUMNS**. You can also list a table's columns with the `mysqlshow db_name tbl_name` command.

The **DESCRIBE** statement provides information similar to **SHOW COLUMNS**. See [Section 12.3.1, “DESCRIBE Syntax”](#).

12.5.4.5. SHOW CONTRIBUTORS Syntax

```
SHOW CONTRIBUTORS
```

The **SHOW CONTRIBUTORS** statement displays information about the people who contribute to MySQL source or to causes that MySQL AB supports. For each contributor, it displays **Name**, **Location**, and **Comment** values.

This statement was added in MySQL 5.1.12.

12.5.4.6. SHOW CREATE DATABASE Syntax

```
SHOW CREATE {DATABASE | SCHEMA} db_name
```

Shows the **CREATE DATABASE** statement that creates the given database. **SHOW CREATE SCHEMA** is a synonym for **SHOW CREATE DATABASE**.

```
mysql> SHOW CREATE DATABASE test\G
***** 1. row *****
      Database: test
Create Database: CREATE DATABASE `test`
                  /*!40100 DEFAULT CHARACTER SET latin1 */

mysql> SHOW CREATE SCHEMA test\G
***** 1. row *****
      Database: test
Create Database: CREATE DATABASE `test`
                  /*!40100 DEFAULT CHARACTER SET latin1 */
```

SHOW CREATE DATABASE quotes table and column names according to the value of the `SQL_QUOTE_SHOW_CREATE` option. See [Section 12.5.3, “SET Syntax”](#).

12.5.4.7. SHOW CREATE EVENT

```
SHOW CREATE EVENT event_name
```

This statement displays the **CREATE EVENT** statement needed to re-create a given event. For example (using the same event `e_daily` defined and then altered in [Section 12.5.4.16, “SHOW EVENTS”](#)):

```
mysql> SHOW CREATE EVENT test.e_daily\G
***** 1. row *****
      Event: e_daily
Create Event: CREATE EVENT e_daily
              ON SCHEDULE EVERY 1 DAY
              STARTS CURRENT_TIMESTAMP + INTERVAL 6 HOUR
```

```

        ENABLE
        COMMENT 'Saves total number of sessions and
                clears the table once per day.'
    DO
        BEGIN
            INSERT INTO site_activity.totals (when, total)
            SELECT CURRENT_TIMESTAMP, COUNT(*)
            FROM site_activity.sessions;
            DELETE FROM site_activity.sessions;
        END
character_set_client: latin1
collation_connection: latin1_swedish_ci
Database Collation: latin1_swedish_ci

```

`character_set_client` is the session value of the `character_set_client` system variable when the event was created. `collation_connection` is the session value of the `collation_connection` system variable when the event was created. `Database Collation` is the collation of the database with which the event is associated. These columns were added in MySQL 5.1.21.

Note that the output reflects the current status of the event (`ENABLE`) rather than the status with which it was created.

This statement was implemented in MySQL 5.1.6.

12.5.4.8. SHOW CREATE PROCEDURE and SHOW CREATE FUNCTION Syntax

```
SHOW CREATE {PROCEDURE | FUNCTION} sp_name
```

These statements are MySQL extensions. Similar to `SHOW CREATE TABLE`, they return the exact string that can be used to re-create the named routine. The statements require that you be the owner of the routine or have `SELECT` access to the `mysql.proc` table.

```

mysql> SHOW CREATE FUNCTION test.hello\G
***** 1. row *****
      Function: hello
      sql_mode:
  Create Function: CREATE FUNCTION `test`.`hello`(s CHAR(20)) »
                   RETURNS CHAR(50)
                   RETURN CONCAT('Hello, ',s, '!')
character_set_client: latin1
collation_connection: latin1_swedish_ci
Database Collation: latin1_swedish_ci

```

`character_set_client` is the session value of the `character_set_client` system variable when the routine was created. `collation_connection` is the session value of the `collation_connection` system variable when the routine was created. `Database Collation` is the collation of the database with which the routine is associated. These columns were added in MySQL 5.1.21.

12.5.4.9. SHOW CREATE TABLE Syntax

```
SHOW CREATE TABLE tbl_name
```

Shows the `CREATE TABLE` statement that creates the given table. This statement also works with views.

```

mysql> SHOW CREATE TABLE t\G
***** 1. row *****
      Table: t
  Create Table: CREATE TABLE t (
    id INT(11) default NULL auto_increment,
    s char(60) default NULL,
    PRIMARY KEY (id)
  ) ENGINE=MyISAM

```

`SHOW CREATE TABLE` quotes table and column names according to the value of the `SQL_QUOTE_SHOW_CREATE` option. See [Section 12.5.3, “SET Syntax”](#).

12.5.4.10. SHOW CREATE TRIGGER Syntax

```
SHOW CREATE TRIGGER trigger_name
```

This statement shows a `CREATE TRIGGER` statement that creates the given trigger.

```
mysql> SHOW CREATE TRIGGER ins_sum\G
***** 1. row *****
Trigger: ins_sum
sql_mode:
SQL Original Statement: CREATE DEFINER=`bob`@`localhost` TRIGGER ins_sum
                        BEFORE INSERT ON account
                        FOR EACH ROW SET @sum = @sum + NEW.amount
character_set_client: latin1
collation_connection: latin1_swedish_ci
Database Collation: latin1_swedish_ci
```

This statement was added in MySQL 5.1.21.

You can also obtain information about trigger objects from `INFORMATION_SCHEMA`, which contains a `TRIGGERS` table. See [Section 23.16, “The INFORMATION_SCHEMA TRIGGERS Table”](#).

12.5.4.11. SHOW CREATE VIEW Syntax

```
SHOW CREATE VIEW view_name
```

This statement shows a `CREATE VIEW` statement that creates the given view.

```
mysql> SHOW CREATE VIEW v\G
***** 1. row *****
View: v
Create View: CREATE ALGORITHM=UNDEFINED
              DEFINER=`bob`@`localhost`
              SQL SECURITY DEFINER VIEW
              `v` AS select 1 AS `a`,2 AS `b`
character_set_client: latin1
collation_connection: latin1_swedish_ci
```

`character_set_client` is the session value of the `character_set_client` system variable when the routine was created. `collation_connection` is the session value of the `collation_connection` system variable when the routine was created. These columns were added in MySQL 5.1.21.

Use of `SHOW CREATE VIEW` requires the `SHOW VIEW` privilege and the `SELECT` privilege for the view in question.

You can also obtain information about view objects from `INFORMATION_SCHEMA`, which contains a `VIEWS` table. See [Section 23.15, “The INFORMATION_SCHEMA VIEWS Table”](#).

12.5.4.12. SHOW DATABASES Syntax

```
SHOW {DATABASES | SCHEMAS}
[LIKE 'pattern' | WHERE expr]
```

`SHOW DATABASES` lists the databases on the MySQL server host. `SHOW SCHEMAS` is a synonym for `SHOW DATABASES`. The `LIKE` clause, if present, indicates which database names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 23.27, “Extensions to SHOW Statements”](#).

You see only those databases for which you have some kind of privilege, unless you have the global `SHOW DATABASES` privilege. You can also get this list using the `mysqlshow` command.

If the server was started with the `--skip-show-database` option, you cannot use this statement at all unless you have the `SHOW DATABASES` privilege.

`SHOW SCHEMAS` can also be used.

12.5.4.13. SHOW ENGINE Syntax

```
SHOW ENGINE engine_name {STATUS | MUTEX}
```

`SHOW ENGINE` displays operational information about a storage engine. The following statements currently are supported:

```
SHOW ENGINE INNODB STATUS
SHOW ENGINE INNODB MUTEX
SHOW ENGINE {NDB | NDBCLUSTER} STATUS
```

Older (and now deprecated) synonyms are `SHOW INNODB STATUS` for `SHOW ENGINE INNODB STATUS` and `SHOW MUTEX STATUS` for `SHOW ENGINE INNODB MUTEX`.

In MySQL 5.0, `SHOW ENGINE INNODB MUTEX` is invoked as `SHOW MUTEX STATUS`. The latter statement displays similar information but in a somewhat different output format.

`SHOW ENGINE BDB LOGS` formerly displayed status information about `BDB` log files. As of MySQL 5.1.12, the `BDB` storage engine is not supported, and this statement produces a warning.

`SHOW ENGINE INNODB STATUS` displays extensive information about the state of the `InnoDB` storage engine.

The `InnoDB` Monitors provide additional information about `InnoDB` processing. See [Section 13.5.11.1, “SHOW ENGINE INNODB STATUS and the InnoDB Monitors”](#).

`SHOW ENGINE INNODB MUTEX` displays `InnoDB` mutex statistics. From MySQL 5.1.2 to 5.1.14, the output fields are:

- **Type**

Always `InnoDB`.

- **Name**

The mutex name and the source file where it is implemented. Example: `&pool->mutex:mem0pool.c`

The mutex name indicates its purpose. For example, the `log_sys` mutex is used by the `InnoDB` logging subsystem and indicates how intensive logging activity is. The `buf_pool` mutex protects the `InnoDB` buffer pool.

- **Status**

The mutex status. The fields contains several values:

- `count` indicates how many times the mutex was requested.
- `spin_waits` indicates how many times the spinlock had to run.
- `spin_rounds` indicates the number of spinlock rounds. (`spin_rounds` divided by `spin_waits` provides the average round count.)
- `os_waits` indicates the number of operating system waits. This occurs when the spinlock did not work (the mutex was not locked during the spinlock and it was necessary to yield to the operating system and wait).
- `os_yields` indicates the number of times a the thread trying to lock a mutex gave up its timeslice and yielded to the operating system (on the presumption that allowing other threads to run will free the mutex so that it can be locked).
- `os_wait_times` indicates the amount of time (in ms) spent in operating system waits, if the `timed_mutexes` system variable is 1 (`ON`). If `timed_mutexes` is 0 (`OFF`), timing is disabled, so `os_wait_times` is 0. `timed_mutexes` is off by default.

From MySQL 5.1.15 on, the output fields are:

- **Type**

Always `InnoDB`.

- **Name**

The source file where the mutex is implemented, and the line number in the file where the mutex is created.

- **Status**

The `os_waits` value, which indicates the number of operating system waits. This occurs when the spinlock did not work (the mutex was not locked during the spinlock and it was necessary to yield to the operating system and wait).

Information from this statement can be used to diagnose system problems. For example, large values of `spin_waits` and `spin_rounds` may indicate scalability problems.

If the server has the `NDBCLUSTER` storage engine enabled, `SHOW ENGINE NDB STATUS` displays cluster status information such as the number of connected data nodes, the cluster connectstring, and cluster binlog epochs, as well as counts of various Cluster API objects created by the MySQL Server when connected to the cluster. Sample output from this statement is shown here:

```
mysql> SHOW ENGINE NDB STATUS;
+-----+-----+-----+
| Type | Name | Status |
+-----+-----+-----+
| ndbcluster | connection | cluster_node_id=7,
connected_host=192.168.0.103, connected_port=1186, number_of_data_nodes=4,
number_of_ready_data_nodes=3, connect_count=0 |
| ndbcluster | NdbTransaction | created=6, free=0, sizeof=212 |
| ndbcluster | NdbOperation | created=8, free=8, sizeof=660 |
| ndbcluster | NdbIndexScanOperation | created=1, free=1, sizeof=744 |
| ndbcluster | NdbIndexOperation | created=0, free=0, sizeof=664 |
| ndbcluster | NdbRecAttr | created=1285, free=1285, sizeof=60 |
| ndbcluster | NdbApiSignal | created=16, free=16, sizeof=136 |
| ndbcluster | NdbLabel | created=0, free=0, sizeof=196 |
| ndbcluster | NdbBranch | created=0, free=0, sizeof=24 |
| ndbcluster | NdbSubroutine | created=0, free=0, sizeof=68 |
| ndbcluster | NdbCall | created=0, free=0, sizeof=16 |
| ndbcluster | NdbBlob | created=1, free=1, sizeof=264 |
| ndbcluster | NdbReceiver | created=4, free=0, sizeof=68 |
| ndbcluster | binlog | latest_epoch=155467, latest_trans_epoch=148126,
latest_received_binlog_epoch=0, latest_handled_binlog_epoch=0,
latest_applied_binlog_epoch=0 |
+-----+-----+-----+
```

The rows with `connection` and `binlog` in the `Name` column were added to the output of this statement in MySQL 5.1. The `Status` column in each of these rows provides information about the MySQL server's connection to the cluster and about the cluster binary log's status, respectively. The `Status` information is in the form of comma-delimited set of name/value pairs.

The `connection` row's `Status` column contains the name/value pairs described in the following table:

Name	Value
<code>cluster_node_id</code>	The node ID of the MySQL server in the cluster
<code>connected_host</code>	The hostname or IP address of the cluster management server to which the MySQL server is connected
<code>connected_port</code>	The port used by the MySQL server to connect to the management server (<code>connected_host</code>)
<code>number_of_data_nodes</code>	The number of data nodes configured for the cluster (that is, the number of <code>[ndbd]</code> sections in the cluster <code>config.ini</code> file)
<code>number_of_ready_data_nodes</code>	The number of data nodes in the cluster that are actually running
<code>connect_count</code>	The number of active connections to cluster data nodes

The `binlog` row's `Status` column contains information relating to MySQL Cluster Replication. The name/value pairs it contains are described in the following table:

Name	Value
<code>latest_epoch</code>	The most recent epoch most recently run on this MySQL server (that is, the sequence number of the most recent transaction run on the server)
<code>latest_trans_epoch</code>	The most recent epoch processed by the cluster's data nodes
<code>latest_received_binlog_epoch</code>	The most recent epoch received by the binlog thread
<code>latest_handled_binlog_epoch</code>	The most recent epoch processed by the binlog thread (for writing to the binlog)
<code>latest_applied_binlog_epoch</code>	The most recent epoch actually written to the binlog

See [Section 16.10, “MySQL Cluster Replication”](#), for more information.

The remaining rows from the output of `SHOW ENGINE NDB STATUS` which are most likely to prove useful in monitoring the cluster are listed here by `Name`:

- **NdbTransaction**: The number and size of **NdbTransaction** objects that have been created. An **NdbTransaction** is created each time a table schema operation (such as **CREATE TABLE** or **ALTER TABLE**) is performed on an **NDB** table.
- **NdbOperation**: The number and size of **NdbOperation** objects that have been created.
- **NdbIndexScanOperation**: The number and size of **NdbIndexScanOperation** objects that have been created.
- **NdbIndexOperation**: The number and size of **NdbIndexOperation** objects that have been created.
- **NdbRecAttr**: The number and size of **NdbRecAttr** objects that have been created. In general, one of these is created each time a data manipulation statement is performed by an SQL node.
- **NdbBlob**: The number and size of **NdbBlob** objects that have been created. An **NdbBlob** is created for each new operation involving a **BLOB** column in an **NDB** table.
- **NdbReceiver**: The number and size of any **NdbReceiver** object that have been created. The number in the **created** column is the same as the number of data nodes in the cluster to which the MySQL server has connected.

Note

SHOW ENGINE NDB STATUS returns an empty result if no operations involving **NDB** tables have been performed during the current session by the MySQL client accessing the SQL node on which this statement is run.

MySQL Enterprise

The **SHOW ENGINE engine_name STATUS** statement provides valuable information about the state of your server. For expert interpretation of this information, subscribe to the MySQL Enterprise Monitor. For more information see <http://www.mysql.com/products/enterprise/advisors.html>.

12.5.4.14. SHOW ENGINES Syntax

SHOW [STORAGE] ENGINES

SHOW ENGINES displays status information about the server's storage engines. This is particularly useful for checking whether a storage engine is supported, or to see what the default engine is. **SHOW TABLE TYPES** is a deprecated synonym.

```
mysql> SHOW ENGINES\G
***** 1. row *****
Engine: MEMORY
Support: YES
Comment: Hash based, stored in memory, useful for temporary tables
Transactions: NO
XA: NO
Savepoints: NO
***** 2. row *****
Engine: MyISAM
Support: DEFAULT
Comment: Default engine as of MySQL 3.23 with great performance
Transactions: NO
XA: NO
Savepoints: NO
***** 3. row *****
Engine: InnoDB
Support: YES
Comment: Supports transactions, row-level locking, and foreign keys
Transactions: YES
XA: YES
Savepoints: YES
***** 4. row *****
Engine: EXAMPLE
Support: YES
Comment: Example storage engine
Transactions: NO
XA: NO
Savepoints: NO
***** 5. row *****
Engine: ARCHIVE
Support: YES
Comment: Archive storage engine
Transactions: NO
XA: NO
Savepoints: NO
***** 6. row *****
Engine: CSV
Support: YES
Comment: CSV storage engine
```

```

Transactions: NO
XA: NO
Savepoints: NO
***** 7. row *****
Engine: BLACKHOLE
Support: YES
Comment: /dev/null storage engine (anything you write »
to it disappears)
Transactions: NO
XA: NO
Savepoints: NO
***** 8. row *****
Engine: FEDERATED
Support: YES
Comment: Federated MySQL storage engine
Transactions: NO
XA: NO
Savepoints: NO
***** 9. row *****
Engine: MRG_MYISAM
Support: YES
Comment: Collection of identical MyISAM tables
Transactions: NO
XA: NO
Savepoints: NO

```

The output from `SHOW ENGINES` may vary according to the MySQL version used and other factors. The values shown in the `Support` column indicate the server's level of support for different features, as shown here:

Value	Meaning
YES	The feature is supported and is active.
NO	The feature is not supported.
DISABLED	The feature is supported but has been disabled.

A value of `NO` means that the server was compiled without support for the feature, so it cannot be activated at runtime.

A value of `DISABLED` occurs either because the server was started with an option that disables the feature, or because not all options required to enable it were given. In the latter case, the error log file should contain a reason indicating why the option is disabled. See [Section 5.11.2, “The Error Log”](#).

You might also see `DISABLED` for a storage engine if the server was compiled to support it, but was started with a `--skip-engine` option. Only the `InnoDB`, and `MERGE` engines can be disabled in this way. For the `NDB Cluster` storage engine, `DISABLED` means the server was compiled with support for MySQL Cluster, but was not started with the `--ndb-cluster` option.

All MySQL servers support `MyISAM` tables, because `MyISAM` is the default storage engine.

The `Transactions`, `XA`, and `Savepoints` columns were added in MySQL 5.1.2. They indicate whether the storage engine supports transactions, XA transactions, and savepoints, respectively.

12.5.4.15. SHOW ERRORS Syntax

```

SHOW ERRORS [LIMIT [offset,] row_count]
SHOW COUNT(*) ERRORS

```

This statement is similar to `SHOW WARNINGS`, except that instead of displaying errors, warnings, and notes, it displays only errors.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See [Section 12.2.7, “SELECT Syntax”](#).

The `SHOW COUNT(*) ERRORS` statement displays the number of errors. You can also retrieve this number from the `error_count` variable:

```

SHOW COUNT(*) ERRORS;
SELECT @@error_count;

```

For more information, see [Section 12.5.4.32, “SHOW WARNINGS Syntax”](#).

12.5.4.16. SHOW EVENTS

```

SHOW EVENTS [FROM schema_name]

```

```
[LIKE 'pattern' | WHERE expr]
```

In its simplest form, **SHOW EVENTS** lists all of the events in the current schema:

```
mysql> SELECT CURRENT_USER(), SCHEMA();
+-----+-----+
| CURRENT_USER() | SCHEMA() |
+-----+-----+
| jon@ghidora    | myschema |
+-----+-----+
1 row in set (0.00 sec)

mysql> SHOW EVENTS\G
***** 1. row *****
      Db: myschema
      Name: e_daily
      Definer: jon@ghidora
      Time zone: SYSTEM
      Type: RECURRING
      Execute at: NULL
      Interval value: 10
      Interval field: INTERVAL_SECOND
      Starts: 2006-02-09 10:41:23
      Ends: 0000-00-00 00:00:00
      Status: ENABLED
      Originator: 0
character_set_client: latin1
collation_connection: latin1_swedish_ci
Database Collation: latin1_swedish_ci
```

The **LIKE** clause, if present, indicates which event names to match. The **WHERE** clause can be given to select rows using more general conditions, as discussed in [Section 23.27, “Extensions to SHOW Statements”](#).

The columns in the output of **SHOW EVENTS** — which are similar to, but not identical to the columns in the **INFORMATION_SCHEMA.EVENTS** table — are shown here:

- **Db**: The schema (database) on which the event is defined.
- **Name**: The name of the event.
- **Time zone**: The time zone in effect when schedule for the event was last modified. If the event's schedule has not been modified since the event was created, then this is the time zone that was in effect at the event's creation. The default value is **SYSTEM**.

This column was added in MySQL 5.1.17. See [Section C.1.10, “Changes in release 5.1.17 \(04 April 2007\)”](#), for important information if you are using the Event Scheduler and are upgrading from MySQL 5.1.16 (or earlier) to MySQL 5.1.17 (or later).

- **Definer**: The user account (*username@hostname*) which created the event.
- **Type**: One of the two values **ONE TIME** (transient) or **RECURRING**.
- **Execute At**: The date and time when a transient event is set to execute. Shown as a **DATETIME** value.

For a recurring event, the value of this column is always **NULL**.

- **Interval Value**: For a recurring event, the number of intervals to wait between event executions.

For a transient event, the value of this column is always **NULL**.

- **Interval Field**: The time units used for the interval which a recurring event waits before repeating.

For a transient event, the value of this column is always **NULL**.

- **Starts**: The start date and time for a recurring event. This is displayed as a **DATETIME** value, and is empty if no start date and time are defined for the event. (Prior to MySQL 5.1.8, it defaulted to '0000-00-00 00:00:00' in such cases.)

For a transient event, the value of this column is always **NULL**.

- **Ends**: The end date and time for a recurring event. This is displayed as a **DATETIME** value, and defaults to '0000-00-00 00:00:00' if no end date and time is defined for the event.

For a transient event, the value of this column is always **NULL**.

- **Status:** The event status. One of `ENABLED`, `DISABLED`, or `SLAVESIDE_DISABLED`.
`SLAVESIDE_DISABLED` was added in MySQL 5.1.18. This value indicates that the creation of the event occurred on another MySQL server acting as a replication master and replicated to the current MySQL server which is acting as a slave, but the event is not presently being executed on the slave.
- **Originator:** The server ID of the MySQL server on which the event was created. Defaults to 0. This column was added in MySQL 5.1.18.
- **character_set_client** is the session value of the `character_set_client` system variable when the routine was created. **collation_connection** is the session value of the `collation_connection` system variable when the routine was created. **Database Collation** is the collation of the database with which the routine is associated. These columns were added in MySQL 5.1.21.

For more information about `SLAVE_DISABLED` and the **Originator** column, see [Section 15.3.1.5, “Replication of Invoked Features”](#).

Note that the action statement is not shown in the output of `SHOW EVENTS`.

Prior to MySQL 5.1.17, the values displayed for **Starts** and **Ends** (other than `'0000-00-00 00:00:00'`) were shown using Universal Time ([Bug#16420](#)). Beginning with MySQL 5.1.17, these times are all given in terms of local time as determined by the MySQL server's `time_zone` setting. See also [Section 23.20, “The INFORMATION_SCHEMA EVENTS Table”](#).

To see events for a different schema, you can use the **FROM** clause. For example, if the `test` schema had been selected in the preceding example, you could view events defined on `myschema` using the following statement:

```
SHOW EVENTS FROM myschema;
```

You can filter the list returned by this statement on the event name using **LIKE** plus a pattern.

This statement was added in MySQL 5.1.6.

See also [Section 23.20, “The INFORMATION_SCHEMA EVENTS Table”](#).

Note

In MySQL 5.1.11 and earlier, `SHOW EVENTS` displayed only those events for which the current user was the definer, and the `SHOW FULL EVENTS` statement was used for viewing events defined by all users on a given schema. `SHOW FULL EVENTS` was removed in MySQL 5.1.12.

12.5.4.17. SHOW GRANTS Syntax

```
SHOW GRANTS [FOR user]
```

This statement lists the **GRANT** statement or statements that must be issued to duplicate the privileges that are granted to a MySQL user account. The account is named using the same format as for the **GRANT** statement; for example, `'jeffrey'@'localhost'`. If you specify only the username part of the account name, a hostname part of `'%'` is used. For additional information about specifying account names, see [Section 12.5.1.3, “GRANT Syntax”](#).

```
mysql> SHOW GRANTS FOR 'root'@'localhost';
+-----+-----+
| Grants for root@localhost |
+-----+-----+
| GRANT ALL PRIVILEGES ON *.* TO 'root'@'localhost' WITH GRANT OPTION |
+-----+-----+
```

To list the privileges granted to the account that you are using to connect to the server, you can use any of the following statements:

```
SHOW GRANTS;
SHOW GRANTS FOR CURRENT_USER;
SHOW GRANTS FOR CURRENT_USER();
```

As of MySQL 5.1.12, if `SHOW GRANTS FOR CURRENT_USER` (or any of the equivalent syntaxes) is used in **DEFINER** context, such as within a stored procedure that is defined with **SQL SECURITY DEFINER**, the grants displayed are those of the definer and

not the invoker.

SHOW GRANTS displays only the privileges granted explicitly to the named account. Other privileges might be available to the account, but they are not displayed. For example, if an anonymous account exists, the named account might be able to use its privileges, but **SHOW GRANTS** will not display them.

12.5.4.18. SHOW INDEX Syntax

```
SHOW INDEX FROM tbl_name [FROM db_name]
```

SHOW INDEX returns table index information. The format resembles that of the [SQLStatistics](#) call in ODBC.

SHOW INDEX returns the following fields:

- **Table**
The name of the table.
- **Non_unique**
0 if the index cannot contain duplicates, 1 if it can.
- **Key_name**
The name of the index.
- **Seq_in_index**
The column sequence number in the index, starting with 1.
- **Column_name**
The column name.
- **Collation**
How the column is sorted in the index. In MySQL, this can have values 'A' (Ascending) or **NULL** (Not sorted).
- **Cardinality**
An estimate of the number of unique values in the index. This is updated by running [ANALYZE TABLE](#) or [myisamchk -a](#). **Cardinality** is counted based on statistics stored as integers, so the value is not necessarily exact even for small tables. The higher the cardinality, the greater the chance that MySQL uses the index when doing joins.
- **Sub_part**
The number of indexed characters if the column is only partly indexed, **NULL** if the entire column is indexed.
- **Packed**
Indicates how the key is packed. **NULL** if it is not.
- **Null**
Contains **YES** if the column may contain **NULL**. If not, the column contains **NO**.
- **Index_type**
The index method used ([BTREE](#), [FULLTEXT](#), [HASH](#), [RTREE](#)).
- **Comment**
Various remarks.

You can use *db_name.tbl_name* as an alternative to the *tbl_name FROM db_name* syntax. These two statements are equival-

ent:

```
SHOW INDEX FROM mytable FROM mydb;
SHOW INDEX FROM mydb.mytable;
```

SHOW KEYS is a synonym for **SHOW INDEX**. You can also list a table's indexes with the `mysqlshow -k db_name tbl_name` command.

12.5.4.19. SHOW INNODB STATUS Syntax

```
SHOW INNODB STATUS
```

In MySQL 5.1, this is a deprecated synonym for **SHOW ENGINE INNODB STATUS**. See [Section 12.5.4.13, “SHOW ENGINE Syntax”](#).

12.5.4.20. SHOW OPEN TABLES Syntax

```
SHOW OPEN TABLES [FROM db_name]
[LIKE 'pattern' | WHERE expr]
```

SHOW OPEN TABLES lists the non-**TEMPORARY** tables that are currently open in the table cache. See [Section 6.4.8, “How MySQL Opens and Closes Tables”](#). The **LIKE** clause, if present, indicates which table names to match. The **WHERE** clause can be given to select rows using more general conditions, as discussed in [Section 23.27, “Extensions to SHOW Statements”](#).

SHOW OPEN TABLES returns the following fields:

- **Database**

The database containing the table.

- **Table**

The table name.

- **In_use**

The number of table locks or lock requests there are for the table. For example, if one client acquires a lock for a table using **LOCK TABLE t1 WRITE**, **In_use** will be 1. If another client issues **LOCK TABLE t1 WRITE** while the table remains locked, the client will block waiting for the lock, but the lock request causes **In_use** to be 2. If the count is zero, the table is open but not currently being used.

- **Name_locked**

Whether the table name is locked. Name locking is used for operations such as dropping or renaming tables.

12.5.4.21. SHOW PLUGINS Syntax

```
SHOW PLUGINS
```

SHOW PLUGINS displays information about known plugins.

```
mysql> SHOW PLUGINS;
+-----+-----+-----+-----+
| Name      | Status | Type          | Library |
+-----+-----+-----+-----+
| MEMORY    | ACTIVE | STORAGE ENGINE | NULL    |
| MyISAM    | ACTIVE | STORAGE ENGINE | NULL    |
| InnoDB    | ACTIVE | STORAGE ENGINE | NULL    |
| ARCHIVE   | ACTIVE | STORAGE ENGINE | NULL    |
| CSV       | ACTIVE | STORAGE ENGINE | NULL    |
| BLACKHOLE | ACTIVE | STORAGE ENGINE | NULL    |
| FEDERATED | ACTIVE | STORAGE ENGINE | NULL    |
| MRG_MYISAM | ACTIVE | STORAGE ENGINE | NULL    |
+-----+-----+-----+-----+
```

SHOW PLUGIN was added in MySQL 5.1.5 and renamed to **SHOW PLUGINS** in 5.1.9. (As of 5.1.9, **SHOW PLUGIN** is deprecated and

generates a warning.)

12.5.4.22. SHOW PRIVILEGES Syntax

SHOW PRIVILEGES

SHOW PRIVILEGES shows the list of system privileges that the MySQL server supports. The exact list of privileges depends on the version of your server.

```
mysql> SHOW PRIVILEGES\G
***** 1. row *****
Privilege: Alter
Context: Tables
Comment: To alter the table
***** 2. row *****
Privilege: Alter routine
Context: Functions,Procedures
Comment: To alter or drop stored functions/procedures
***** 3. row *****
Privilege: Create
Context: Databases,Tables,Indexes
Comment: To create new databases and tables
***** 4. row *****
Privilege: Create routine
Context: Functions,Procedures
Comment: To use CREATE FUNCTION/PROCEDURE
***** 5. row *****
Privilege: Create temporary tables
Context: Databases
Comment: To use CREATE TEMPORARY TABLE
...
```

12.5.4.23. SHOW PROCEDURE CODE and SHOW FUNCTION CODE Syntax

SHOW {PROCEDURE | FUNCTION} CODE *sp_name*

These statements are MySQL extensions that are available only for servers that have been built with debugging support. They display a representation of the internal implementation of the named routine. The statements require that you be the owner of the routine or have **SELECT** access to the `mysql.proc` table.

If the named routine is available, each statement produces a result set. Each row in the result set corresponds to one “instruction” in the routine. The first column is **Pos**, which is an ordinal number beginning with 0. The second column is **Instruction**, which contains an SQL statement (usually changed from the original source), or a directive which has meaning only to the stored-routine handler.

```
mysql> DELIMITER //
mysql> CREATE PROCEDURE p1 ()
-> BEGIN
->   DECLARE fanta INT DEFAULT 55;
->   DROP TABLE t2;
->   LOOP
->     INSERT INTO t3 VALUES (fanta);
->   END LOOP;
-> END//
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW PROCEDURE CODE p1//
+-----+-----+
| Pos | Instruction |
+-----+-----+
| 0   | set fanta@0 55 |
| 1   | stmt 9 "DROP TABLE t2" |
| 2   | stmt 5 "INSERT INTO t3 VALUES (fanta)" |
| 3   | jump 2 |
+-----+-----+
4 rows in set (0.00 sec)
```

In this example, the non-executable **BEGIN** and **END** statements have disappeared, and for the **DECLARE variable_name** statement, only the executable part appears (the part where the default is assigned). For each statement that is taken from source, there is a code word **stmt** followed by a type (9 means **DROP**, 5 means **INSERT**, and so on). The final row contains an instruction **jump 2**, meaning **GOTO instruction #2**.

These statements were added in MySQL 5.1.3.

12.5.4.24. SHOW PROCEDURE STATUS and SHOW FUNCTION STATUS Syntax

```
SHOW {PROCEDURE | FUNCTION} STATUS
[LIKE 'pattern' | WHERE expr]
```

These statements are MySQL extensions. They return characteristics of routines, such as the database, name, type, creator, creation and modification dates, and character set information. The **LIKE** clause, if present, indicates which procedure or function names to match. The **WHERE** clause can be given to select rows using more general conditions, as discussed in [Section 23.27, “Extensions to SHOW Statements”](#).

```
mysql> SHOW FUNCTION STATUS LIKE 'hello'\G
***** 1. row *****
      Db: test
      Name: hello
      Type: FUNCTION
      Definer: testuser@localhost
      Modified: 2004-08-03 15:29:37
      Created: 2004-08-03 15:29:37
      Security_type: DEFINER
      Comment:
character_set_client: latin1
collation_connection: latin1_swedish_ci
Database Collation: latin1_swedish_ci
```

character_set_client is the session value of the **character_set_client** system variable when the routine was created. **collation_connection** is the session value of the **collation_connection** system variable when the routine was created. **Database Collation** is the collation of the database with which the routine is associated. These columns were added in MySQL 5.1.21.

You can also get information about stored routines from the **ROUTINES** table in **INFORMATION_SCHEMA**. See [Section 23.14, “The INFORMATION_SCHEMA ROUTINES Table”](#).

12.5.4.25. SHOW PROCESSLIST Syntax

```
SHOW [FULL] PROCESSLIST
```

SHOW PROCESSLIST shows you which threads are running. You can also get this information from the **INFORMATION_SCHEMA PROCESSLIST** table or the **mysqladmin processlist** command. If you have the **PROCESS** privilege, you can see all threads. Otherwise, you can see only your own threads (that is, threads associated with the MySQL account that you are using). If you do not use the **FULL** keyword, only the first 100 characters of each statement are shown in the **Info** field.

MySQL Enterprise

Subscribers to MySQL Enterprise Monitor receive instant notification and expert advice on resolution when there are too many concurrent processes. For more information see, <http://www.mysql.com/products/enterprise/advisors.html>.

This statement is very useful if you get the “too many connections” error message and want to find out what is going on. MySQL reserves one extra connection to be used by accounts that have the **SUPER** privilege, to ensure that administrators should always be able to connect and check the system (assuming that you are not giving this privilege to all your users).

Threads can be killed with the **KILL** statement. See [Section 12.5.5.3, “KILL Syntax”](#).

Here is an example of what **SHOW PROCESSLIST** output looks like:

```
mysql> SHOW FULL PROCESSLIST\G
***** 1. row *****
Id: 1
User: system user
Host:
db: NULL
Command: Connect
Time: 1030455
State: Waiting for master to send event
Info: NULL
***** 2. row *****
Id: 2
User: system user
Host:
db: NULL
Command: Connect
Time: 1004
State: Has read all relay log; waiting for the slave
      I/O thread to update it
Info: NULL
***** 3. row *****
```

```
Id: 3112
User: replikator
Host: artemis:2204
db: NULL
Command: Binlog Dump
Time: 2144
State: Has sent all binlog to slave; waiting for binlog to be updated
Info: NULL
***** 4. row *****
Id: 3113
User: replikator
Host: iconnect2:45781
db: NULL
Command: Binlog Dump
Time: 2086
State: Has sent all binlog to slave; waiting for binlog to be updated
Info: NULL
***** 5. row *****
Id: 3123
User: stefan
Host: localhost
db: apollon
Command: Query
Time: 0
State: NULL
Info: SHOW FULL PROCESSLIST
5 rows in set (0.00 sec)
```

The columns have the following meaning:

- **Id**

The connection identifier.

- **User**

The MySQL user who issued the statement. If this is **system user**, it refers to a non-client thread spawned by the server to handle tasks internally. This could be the I/O or SQL thread used on replication slaves or a delayed-row handler. **unauthenticated user** refers to a thread that has become associated with a client connection but for which authentication of the client user has not yet been done. **event_scheduler** refers to the thread that monitors scheduled events. For **system user** or **event_scheduler**, there is no host specified in the **Host** column.

- **Host**

The hostname of the client issuing the statement (except for **system user** where there is no host). **SHOW PROCESSLIST** reports the hostname for TCP/IP connections in **host_name:client_port** format to make it easier to determine which client is doing what.

- **db**

The default database, if one is selected, otherwise **NULL**.

- **Command**

The type of command the thread is executing. Descriptions for thread commands can be found at [Section 6.5.5, “Examining Thread Information”](#). The value of this column corresponds to the **COM_XXX** commands of the client/server protocol. See [Section 5.2.5, “Status Variables”](#)

- **Time**

The time in seconds that the thread has been in its current state.

- **State**

An action, event, or state that indicates what the thread is doing. Descriptions for **State** values can be found at [Section 6.5.5, “Examining Thread Information”](#).

Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that needs to be investigated.

For the **SHOW PROCESSLIST** statement, the value of **State** is **NULL**.

- **Info**

The statement that the thread is executing, or **NULL** if it is not executing any statement.

12.5.4.26. SHOW SCHEDULER STATUS Syntax

```
SHOW SCHEDULER STATUS
```

This statement provides debugging information regarding the Event Scheduler's state. It is supported only in **-debug** builds of MySQL 5.1.11, and was removed in 5.1.12 and subsequent releases.

Sample output is shown here:

Name	Value
scheduler state	INITIALIZED
thread_id	NULL
scheduler last locked at	init_scheduler::313
scheduler last unlocked at	init_scheduler::318
scheduler waiting on condition	0
scheduler workers count	0
scheduler executed events	0
scheduler data locked	0
queue element count	1
queue data locked	0
queue data attempting lock	0
queue last locked at	create_event::218
queue last unlocked at	create_event::222
queue last attempted lock at	::0
queue waiting on condition	0
next activation at	0-00-00 00:00:00

In MySQL 5.1.12 and later, this information can be obtained using `mysqladmin debug`. (See [Section 7.10, “mysqladmin — Client for Administering a MySQL Server”](#).) For more information about obtaining Event Scheduler status information, see [Section 21.4, “Event Scheduler Status”](#).

12.5.4.27. SHOW STATUS Syntax

```
SHOW [GLOBAL | SESSION] STATUS
[LIKE 'pattern' | WHERE expr]
```

SHOW STATUS provides server status information. This information also can be obtained using the `mysqladmin extended-status` command. The **LIKE** clause, if present, indicates which variable names to match. The **WHERE** clause can be given to select rows using more general conditions, as discussed in [Section 23.27, “Extensions to SHOW Statements”](#).

Partial output is shown here. The list of names and values may be different for your server. The meaning of each variable is given in [Section 5.2.5, “Status Variables”](#).

```
mysql> SHOW STATUS;
```

Variable_name	Value
Aborted_clients	0
Aborted_connects	0
Bytes_received	155372598
Bytes_sent	1176560426
Connections	30023
Created_tmp_disk_tables	0
Created_tmp_tables	8340
Created_tmp_files	60
...	
Open_tables	1
Open_files	2
Open_streams	0
Opened_tables	44600
Questions	2026873
...	
Table_locks_immediate	1920382
Table_locks_waited	0
Threads_cached	0
Threads_created	30022
Threads_connected	1
Threads_running	1

Uptime	80380

With a **LIKE** clause, the statement displays only rows for those variables with names that match the pattern:

```
mysql> SHOW STATUS LIKE 'Key%';
```

Variable_name	Value
Key_blocks_used	14955
Key_read_requests	96854827
Key_reads	162040
Key_write_requests	7589728
Key_writes	3813196

With the **GLOBAL** modifier, **SHOW STATUS** displays the status values for all connections to MySQL. With **SESSION**, it displays the status values for the current connection. If no modifier is present, the default is **SESSION**. **LOCAL** is a synonym for **SESSION**.

Some status variables have only a global value. For these, you get the same value for both **GLOBAL** and **SESSION**. The scope for each status variable is listed at [Section 5.2.5, “Status Variables”](#).

MySQL Enterprise

Status variables provide valuable clues to the state of your servers. For expert interpretation of the information provided by status variables, subscribe to the MySQL Enterprise Monitor. For more information see <http://www.mysql.com/products/enterprise/advisors.html>.

12.5.4.28. SHOW TABLE STATUS Syntax

```
SHOW TABLE STATUS [FROM db_name]
[LIKE 'pattern' | WHERE expr]
```

SHOW TABLE STATUS works like **SHOW TABLES**, but provides a lot of information about each table. You can also get this list using the `mysqlshow --status db_name` command. The **LIKE** clause, if present, indicates which table names to match. The **WHERE** clause can be given to select rows using more general conditions, as discussed in [Section 23.27, “Extensions to SHOW Statements”](#).

This statement also displays information about views.

SHOW TABLE STATUS returns the following fields:

- **Name**
The name of the table.
- **Engine**
The storage engine for the table. See [Chapter 13, Storage Engines](#).
- **Version**
The version number of the table's `.frm` file.
- **Row_format**
The row storage format (**Fixed**, **Dynamic**, **Compressed**, **Redundant**, **Compact**). The format of **InnoDB** tables is reported as **Redundant** or **Compact**.
- **Rows**
The number of rows. Some storage engines, such as **MyISAM**, store the exact count. For other storage engines, such as **InnoDB**, this value is an approximation, and may vary from the actual value by as much as 40 to 50%. In such cases, use **SELECT COUNT(*)** to obtain an accurate count.

The **Rows** value is **NULL** for tables in the **INFORMATION_SCHEMA** database.
- **Avg_row_length**

The average row length.

- **Data_length**

The length of the data file.

- **Max_data_length**

The maximum length of the data file. This is the total number of bytes of data that can be stored in the table, given the data pointer size used.

- **Index_length**

The length of the index file.

- **Data_free**

The number of allocated but unused bytes.

- **Auto_increment**

The next **AUTO_INCREMENT** value.

- **Create_time**

When the table was created.

- **Update_time**

When the data file was last updated. For some storage engines, this value is **NULL**. For example, **InnoDB** stores multiple tables in its tablespace and the data file timestamp does not apply.

- **Check_time**

When the table was last checked. Not all storage engines update this time, in which case the value is always **NULL**.

- **Collation**

The table's character set and collation.

- **Checksum**

The live checksum value (if any).

- **Create_options**

Extra options used with **CREATE TABLE**. The original options supplied when **CREATE TABLE** is called are retained and the options reported here may differ from the active table settings and options.

- **Comment**

The comment used when creating the table (or information as to why MySQL could not access the table information).

In the table comment, **InnoDB** tables report the free space of the tablespace to which the table belongs. For a table located in the shared tablespace, this is the free space of the shared tablespace. If you are using multiple tablespaces and the table has its own tablespace, the free space is for only that table.

For **MEMORY** tables, the **Data_length**, **Max_data_length**, and **Index_length** values approximate the actual amount of allocated memory. The allocation algorithm reserves memory in large amounts to reduce the number of allocation operations.

For **NDB Cluster** tables, the output of this statement shows appropriate values for the **Avg_row_length** and **Data_length** columns, with the exception that **BLOB** columns are not taken into account. In addition, the number of replicas is shown in the **Comment** column (as **number_of_replicas**).

For views, all the fields displayed by **SHOW TABLE STATUS** are **NULL** except that **Name** indicates the view name and **Comment** says

view.

12.5.4.29. SHOW TABLES Syntax

```
SHOW [FULL] TABLES [FROM db_name]
      [LIKE 'pattern' | WHERE expr]
```

SHOW TABLES lists the non-**TEMPORARY** tables in a given database. You can also get this list using the `mysqlshow db_name` command. The **LIKE** clause, if present, indicates which table names to match. The **WHERE** clause can be given to select rows using more general conditions, as discussed in [Section 23.27, “Extensions to SHOW Statements”](#).

This statement also lists any views in the database. The **FULL** modifier is supported such that **SHOW FULL TABLES** displays a second output column. Values for the second column are **BASE TABLE** for a table and **VIEW** for a view.

Note

If you have no privileges for a table, the table does not show up in the output from **SHOW TABLES** or `mysqlshow db_name`.

12.5.4.30. SHOW TRIGGERS Syntax

```
SHOW TRIGGERS [FROM db_name]
      [LIKE 'pattern' | WHERE expr]
```

SHOW TRIGGERS lists the triggers currently defined on the MySQL server. This statement requires the **SUPER** privilege. The **LIKE** clause, if present, indicates which trigger names to match. The **WHERE** clause can be given to select rows using more general conditions, as discussed in [Section 23.27, “Extensions to SHOW Statements”](#).

For the trigger `ins_sum` as defined in [Section 20.3, “Using Triggers”](#), the output of this statement is as shown here:

```
mysql> SHOW TRIGGERS LIKE 'acc%\G
***** 1. row *****
      Trigger: ins_sum
      Event: INSERT
      Table: account
      Statement: SET @sum = @sum + NEW.amount
      Timing: BEFORE
      Created: NULL
      sql_mode:
      Definer: myname@localhost
character_set_client: latin1
collation_connection: latin1_swedish_ci
Database Collation: latin1_swedish_ci
```

character_set_client is the session value of the **character_set_client** system variable when the trigger was created. **collation_connection** is the session value of the **collation_connection** system variable when the trigger was created. **Database Collation** is the collation of the database with which the trigger is associated. These columns were added in MySQL 5.1.21.

Note

When using a **LIKE** clause with **SHOW TRIGGERS**, the expression to be matched (*expr*) is compared with the name of the table on which the trigger is declared, and not with the name of the trigger:

```
mysql> SHOW TRIGGERS LIKE 'ins%';
Empty set (0.01 sec)
```

A brief explanation of the columns in the output of this statement is shown here:

- **Trigger**

The name of the trigger.

- **Event**

The event that causes trigger activation: one of **'INSERT'**, **'UPDATE'**, or **'DELETE'**.

- **Table**

The table for which the trigger is defined.

- **Statement**

The statement to be executed when the trigger is activated. This is the same as the text shown in the `ACTION_STATEMENT` column of `INFORMATION_SCHEMA.TRIGGERS`.

- **Timing**

One of the two values `'BEFORE'` or `'AFTER'`.

- **Created**

Currently, the value of this column is always `NULL`.

- **sql_mode**

The SQL mode in effect when the trigger executes.

- **Definer**

The account that created the trigger.

See also [Section 23.16, “The INFORMATION_SCHEMA TRIGGERS Table”](#).

12.5.4.31. SHOW VARIABLES Syntax

```
SHOW [GLOBAL | SESSION] VARIABLES
     [LIKE 'pattern' | WHERE expr]
```

`SHOW VARIABLES` shows the values of MySQL system variables. This information also can be obtained using the `mysqladmin variables` command. The `LIKE` clause, if present, indicates which variable names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 23.27, “Extensions to SHOW Statements”](#).

With the `GLOBAL` modifier, `SHOW VARIABLES` displays the values that are used for new connections to MySQL. With `SESSION`, it displays the values that are in effect for the current connection. If no modifier is present, the default is `SESSION`. `LOCAL` is a synonym for `SESSION`.

If the default system variable values are unsuitable, you can set them using command options when `mysqld` starts, and most can be changed at runtime with the `SET` statement. See [Section 5.2.4, “Using System Variables”](#), and [Section 12.5.3, “SET Syntax”](#).

Partial output is shown here. The list of names and values may be different for your server. [Section 5.2.3, “System Variables”](#), describes the meaning of each variable, and [Section 6.5.2, “Tuning Server Parameters”](#), provides information about tuning them.

```
mysql> SHOW VARIABLES;
+-----+-----+
| Variable_name | Value |
+-----+-----+
| auto_increment_increment | 1 |
| auto_increment_offset | 1 |
| automatic_sp_privileges | ON |
| back_log | 50 |
| basedir | /home/jon/bin/mysql-5.1/ |
| binlog_cache_size | 32768 |
| bulk_insert_buffer_size | 8388608 |
| character_set_client | latin1 |
| character_set_connection | latin1 |
| ... | ... |
| max_user_connections | 0 |
| max_write_lock_count | 4294967295 |
| multi_range_count | 256 |
| myisam_data_pointer_size | 6 |
| myisam_max_sort_file_size | 2147483647 |
| myisam_recover_options | OFF |
| myisam_repair_threads | 1 |
| myisam_sort_buffer_size | 8388608 |
| ndb_autoincrement_prefetch_sz | 32 |
| ndb_cache_check_time | 0 |
| ndb_force_send | ON |
| ... | ... |
```

time_zone	SYSTEM
timed_mutexes	OFF
tmp_table_size	33554432
tmpdir	
transaction_alloc_block_size	8192
transaction_prealloc_size	4096
tx_isolation	REPEATABLE-READ
updatable_views_with_limit	YES
version	5.1.6-alpha-log
version_comment	Source distribution
version_compile_machine	i686
version_compile_os	suse-linux
wait_timeout	28800

With a [LIKE](#) clause, the statement displays only rows for those variables with names that match the pattern. To obtain the row for a specific variable, use a [LIKE](#) clause as shown:

```
SHOW VARIABLES LIKE 'max_join_size';
SHOW SESSION VARIABLES LIKE 'max_join_size';
```

To get a list of variables whose name match a pattern, use the `'%'` wildcard character in a [LIKE](#) clause:

```
SHOW VARIABLES LIKE '%size%';
SHOW GLOBAL VARIABLES LIKE '%size%';
```

Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because `'_'` is a wildcard that matches any single character, you should escape it as `'\_'` to match it literally. In practice, this is rarely necessary.

12.5.4.32. SHOW WARNINGS Syntax

```
SHOW WARNINGS [LIMIT [offset,] row_count]
SHOW COUNT(*) WARNINGS
```

[SHOW WARNINGS](#) shows the error, warning, and note messages that resulted from the last statement that generated messages, or nothing if the last statement that used a table generated no messages. A related statement, [SHOW ERRORS](#), shows only the errors. See [Section 12.5.4.15, “SHOW ERRORS Syntax”](#).

The list of messages is reset for each new statement that uses a table.

The [SHOW COUNT\(*\) WARNINGS](#) statement displays the total number of errors, warnings, and notes. You can also retrieve this number from the `warning_count` variable:

```
SHOW COUNT(*) WARNINGS;
SELECT @@warning_count;
```

The value of `warning_count` might be greater than the number of messages displayed by [SHOW WARNINGS](#) if the `max_error_count` system variable is set so low that not all messages are stored. An example shown later in this section demonstrates how this can happen.

The [LIMIT](#) clause has the same syntax as for the [SELECT](#) statement. See [Section 12.2.7, “SELECT Syntax”](#).

The MySQL server sends back the total number of errors, warnings, and notes resulting from the last statement. If you are using the C API, this value can be obtained by calling `mysql_warning_count()`. See [Section 25.2.3.72, “mysql_warning_count\(\)”](#).

Warnings are generated for statements such as [LOAD DATA INFILE](#) and DML statements such as [INSERT](#), [UPDATE](#), [CREATE TABLE](#), and [ALTER TABLE](#).

The following [DROP TABLE](#) statement results in a note:

```
mysql> DROP TABLE IF EXISTS no_such_table;
mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Note  | 1051 | Unknown table 'no_such_table'             |
+-----+-----+-----+
```

Here is a simple example that shows a syntax warning for [CREATE TABLE](#) and conversion warnings for [INSERT](#):

```
mysql> CREATE TABLE t1 (a TINYINT NOT NULL, b CHAR(4)) TYPE=MyISAM;
Query OK, 0 rows affected, 1 warning (0.00 sec)
mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1287
Message: 'TYPE=storage_engine' is deprecated, use
        'ENGINE=storage_engine' instead
1 row in set (0.00 sec)

mysql> INSERT INTO t1 VALUES(10,'mysql'),(NULL,'test'),
-> (300,'Open Source');
Query OK, 3 rows affected, 4 warnings (0.01 sec)
Records: 3 Duplicates: 0 Warnings: 4

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1265
Message: Data truncated for column 'b' at row 1
***** 2. row *****
Level: Warning
Code: 1263
Message: Data truncated, NULL supplied to NOT NULL column 'a' at row 2
***** 3. row *****
Level: Warning
Code: 1264
Message: Data truncated, out of range for column 'a' at row 3
***** 4. row *****
Level: Warning
Code: 1265
Message: Data truncated for column 'b' at row 3
4 rows in set (0.00 sec)
```

The maximum number of error, warning, and note messages to store is controlled by the `max_error_count` system variable. By default, its value is 64. To change the number of messages you want stored, change the value of `max_error_count`. In the following example, the `ALTER TABLE` statement produces three warning messages, but only one is stored because `max_error_count` has been set to 1:

```
mysql> SHOW VARIABLES LIKE 'max_error_count';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| max_error_count | 64    |
+-----+-----+
1 row in set (0.00 sec)

mysql> SET max_error_count=1;
Query OK, 0 rows affected (0.00 sec)

mysql> ALTER TABLE t1 MODIFY b CHAR;
Query OK, 3 rows affected, 3 warnings (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 3

mysql> SELECT @@warning_count;
+-----+
| @@warning_count |
+-----+
| 3               |
+-----+
1 row in set (0.01 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Warning | 1263 | Data truncated for column 'b' at row 1 |
+-----+-----+-----+
1 row in set (0.00 sec)
```

To disable warnings, set `max_error_count` to 0. In this case, `warning_count` still indicates how many warnings have occurred, but none of the messages are stored.

You can set the `SQL_NOTES` session variable to 0 to cause `Note`-level warnings not to be recorded.

12.5.5. Other Administrative Statements

12.5.5.1. CACHE INDEX Syntax

```
CACHE INDEX
tbl_index_list [, tbl_index_list] ...
```

```
IN key_cache_name
tbl_index_list:
  tbl_name [[INDEX|KEY] (index_name [, index_name] ...)]
```

The **CACHE INDEX** statement assigns table indexes to a specific key cache. It is used only for **MyISAM** tables.

The following statement assigns indexes from the tables **t1**, **t2**, and **t3** to the key cache named **hot_cache**:

```
mysql> CACHE INDEX t1, t2, t3 IN hot_cache;
```

Table	Op	Msg_type	Msg_text
test.t1	assign_to_keycache	status	OK
test.t2	assign_to_keycache	status	OK
test.t3	assign_to_keycache	status	OK

The syntax of **CACHE INDEX** enables you to specify that only particular indexes from a table should be assigned to the cache. The current implementation assigns all the table's indexes to the cache, so there is no reason to specify anything other than the table name.

The key cache referred to in a **CACHE INDEX** statement can be created by setting its size with a parameter setting statement or in the server parameter settings. For example:

```
mysql> SET GLOBAL keycache1.key_buffer_size=128*1024;
```

Key cache parameters can be accessed as members of a structured system variable. See [Section 5.2.4.1, “Structured System Variables”](#).

A key cache must exist before you can assign indexes to it:

```
mysql> CACHE INDEX t1 IN non_existent_cache;
ERROR 1284 (HY000): Unknown key cache 'non_existent_cache'
```

By default, table indexes are assigned to the main (default) key cache created at the server startup. When a key cache is destroyed, all indexes assigned to it become assigned to the default key cache again.

Index assignment affects the server globally: If one client assigns an index to a given cache, this cache is used for all queries involving the index, no matter which client issues the queries.

12.5.5.2. FLUSH Syntax

```
FLUSH [LOCAL | NO_WRITE_TO_BINLOG]
      flush_option [, flush_option] ...
```

The **FLUSH** statement clears or reloads various internal caches used by MySQL. To execute **FLUSH**, you must have the **RELOAD** privilege.

The **RESET** statement is similar to **FLUSH**. See [Section 12.5.5.5, “RESET Syntax”](#).

flush_option can be any of the following:

- **HOSTS**

Empties the host cache tables. You should flush the host tables if some of your hosts change IP number or if you get the error message **Host 'host_name' is blocked**. When more than **max_connect_errors** errors occur successively for a given host while connecting to the MySQL server, MySQL assumes that something is wrong and blocks the host from further connection requests. Flushing the host tables allows the host to attempt to connect again. See [Section B.1.2.5, “Host 'host_name' is blocked”](#). You can start **mysqld** with **--max_connect_errors=999999999** to avoid this error message.

- **DES_KEY_FILE**

Reloads the DES keys from the file that was specified with the **--des-key-file** option at server startup time.

- **LOGS**

Closes and reopens all log files. If binary logging is enabled, the sequence number of the binary log file is incremented by one relat-

ive to the previous file. On Unix, this is the same thing as sending a `SIGHUP` signal to the `mysqld` server (except on some Mac OS X 10.3 versions where `mysqld` ignores `SIGHUP` and `SIGQUIT`).

If the server was started with the `--log-error` option, `FLUSH LOGS` causes it to rename the current error log file with a suffix of `-old` and create a new empty log file. No renaming occurs if the `--log-error` option was not given.

- **MASTER (DEPRECATED)**. Deletes all binary logs, resets the binary log index file and creates a new binary log. `FLUSH MASTER` is deprecated in favor of `RESET MASTER`, and is supported for backwards compatibility only. See [Section 12.6.1.2, “RESET MASTER Syntax”](#).

- **PRIVILEGES**

Reloads the privileges from the grant tables in the `mysql` database.

- **QUERY CACHE**

Defragment the query cache to better utilize its memory. `FLUSH QUERY CACHE` does not remove any queries from the cache, unlike `RESET QUERY CACHE`.

- **SLAVE (DEPRECATED)**. Resets all replication slave parameters, including relay log files and replication position in the master's binary logs. `FLUSH SLAVE` is deprecated in favour of `RESET SLAVE`, and is supported for backwards compatibility only. See [Section 12.6.2.5, “RESET SLAVE Syntax”](#).

- **STATUS**

This option adds the current thread's session status variable values to the global values and resets the session values to zero. It also resets the counters for key caches (default and named) to zero and sets `Max_used_connections` to the current number of open connections. This is something you should use only when debugging a query. See [Section 1.8, “How to Report Bugs or Problems”](#).

- **{TABLE | TABLES} [tbl_name [, tbl_name] ...]**

When no tables are named, closes all open tables and forces all tables in use to be closed. This also flushes the query cache. With one or more table names, flushes only the given tables. `FLUSH TABLES` also removes all query results from the query cache, like the `RESET QUERY CACHE` statement.

- **TABLES WITH READ LOCK**

Closes all open tables and locks all tables for all databases with a read lock until you explicitly release the lock by executing `UNLOCK TABLES`. This is a very convenient way to get backups if you have a filesystem such as Veritas that can take snapshots in time.

`FLUSH TABLES WITH READ LOCK` acquires a global read lock and not table locks, so it is not subject to the same behavior as `LOCK TABLES` and `UNLOCK TABLES` with respect to table locking and implicit commits:

- `UNLOCK TABLES` commits a transaction only if any tables currently have been locked with `LOCK TABLES`. This does not occur for `UNLOCK TABLES` following `FLUSH TABLES WITH READ LOCK` because the latter statement does not acquire table-level locks.
 - Beginning a transaction causes table locks acquired with `LOCK TABLES` to be released, as though you had executed `UNLOCK TABLES`. Beginning a transaction does not release a global read lock acquired with `FLUSH TABLES WITH READ LOCK`.
- **USER_RESOURCES**

Resets all per-hour user resources to zero. This enables clients that have reached their hourly connection, query, or update limits to resume activity immediately. `FLUSH USER_RESOURCES` does not apply to the limit on maximum simultaneous connections. See [Section 12.5.1.3, “GRANT Syntax”](#).

By default, `FLUSH` statements are written to the binary log so that such statements used on a MySQL server acting as a replication master will be replicated to replication slaves. Logging can be suppressed with the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

Note

`FLUSH LOGS`, `FLUSH MASTER`, `FLUSH SLAVE`, and `FLUSH TABLES WITH READ LOCK` are not logged in any

- case because they would cause problems if replicated to a slave.

You can also access some of these statements with the `mysqladmin` utility, using the `flush-hosts`, `flush-logs`, `flush-privileges`, `flush-status`, or `flush-tables` commands.

Note

It is not possible in MySQL 5.1 to issue `FLUSH` statements within stored functions or triggers. However, you may use `FLUSH` in stored procedures, so long as these are not called from stored functions or triggers. See [Section D.1](#), “Restrictions on Stored Routines and Triggers”.

See also [Section 12.5.5.5](#), “RESET Syntax”, for information about how the `RESET` statement is used with replication.

12.5.5.3. KILL Syntax

```
KILL [CONNECTION | QUERY] thread_id
```

Each connection to `mysqld` runs in a separate thread. You can see which threads are running with the `SHOW PROCESSLIST` statement and kill a thread with the `KILL thread_id` statement.

`KILL` allows the optional `CONNECTION` or `QUERY` modifier:

- `KILL CONNECTION` is the same as `KILL` with no modifier: It terminates the connection associated with the given *thread_id*.
- `KILL QUERY` terminates the statement that the connection is currently executing, but leaves the connection itself intact.

If you have the `PROCESS` privilege, you can see all threads. If you have the `SUPER` privilege, you can kill all threads and statements. Otherwise, you can see and kill only your own threads and statements.

You can also use the `mysqladmin processlist` and `mysqladmin kill` commands to examine and kill threads.

Note

You cannot use `KILL` with the Embedded MySQL Server library, because the embedded server merely runs inside the threads of the host application. It does not create any connection threads of its own.

When you use `KILL`, a thread-specific kill flag is set for the thread. In most cases, it might take some time for the thread to die, because the kill flag is checked only at specific intervals:

- In `SELECT`, `ORDER BY` and `GROUP BY` loops, the flag is checked after reading a block of rows. If the kill flag is set, the statement is aborted.
- During `ALTER TABLE`, the kill flag is checked before each block of rows are read from the original table. If the kill flag was set, the statement is aborted and the temporary table is deleted.
- During `UPDATE` or `DELETE` operations, the kill flag is checked after each block read and after each updated or deleted row. If the kill flag is set, the statement is aborted. Note that if you are not using transactions, the changes are not rolled back.
- `GET_LOCK()` aborts and returns `NULL`.
- An `INSERT DELAYED` thread quickly flushes (inserts) all rows it has in memory and then terminates.
- If the thread is in the table lock handler (state: `Locked`), the table lock is quickly aborted.
- If the thread is waiting for free disk space in a write call, the write is aborted with a “disk full” error message.
-

Warning

Killing a `REPAIR TABLE` or `OPTIMIZE TABLE` operation on a `MyISAM` table results in a table that is corrupted and unusable. Any reads or writes to such a table fail until you optimize or repair it again (without interruption).

12.5.5.4. LOAD INDEX INTO CACHE Syntax

```
LOAD INDEX INTO CACHE
  tbl_index_list [, tbl_index_list] ...
tbl_index_list:
  tbl_name
  [[INDEX|KEY] (index_name[, index_name] ...)]
  [IGNORE LEAVES]
```

The **LOAD INDEX INTO CACHE** statement preloads a table index into the key cache to which it has been assigned by an explicit **CACHE INDEX** statement, or into the default key cache otherwise. **LOAD INDEX INTO CACHE** is used only for **MyISAM** tables. It is not supported for tables having user-defined partitioning (see [Section 17.5, “Restrictions and Limitations on Partitioning”](#)).

The **IGNORE LEAVES** modifier causes only blocks for the non-leaf nodes of the index to be preloaded.

The following statement preloads nodes (index blocks) of indexes for the tables **t1** and **t2**:

```
mysql> LOAD INDEX INTO CACHE t1, t2 IGNORE LEAVES;
+-----+-----+-----+-----+
| Table | Op          | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.t1 | preload_keys | status   | OK       |
| test.t2 | preload_keys | status   | OK       |
+-----+-----+-----+-----+
```

This statement preloads all index blocks from **t1**. It preloads only blocks for the non-leaf nodes from **t2**.

The syntax of **LOAD INDEX INTO CACHE** enables you to specify that only particular indexes from a table should be preloaded. The current implementation preloads all the table's indexes into the cache, so there is no reason to specify anything other than the table name.

LOAD INDEX INTO CACHE ... IGNORE LEAVES fails unless all indexes in a table have the same block size. (Prior to MySQL 5.1.19, it fails even without **IGNORE LEAVES**.) You can determine index block sizes for a table by using **myisamchk -dv** and checking the **Blocksize** column.

12.5.5.5. RESET Syntax

```
RESET reset_option [, reset_option] ...
```

The **RESET** statement is used to clear the state of various server operations. You must have the **RELOAD** privilege to execute **RESET**.

RESET acts as a stronger version of the **FLUSH** statement. See [Section 12.5.5.2, “FLUSH Syntax”](#).

reset_option can be any of the following:

- **MASTER**

Deletes all binary logs listed in the index file, resets the binary log index file to be empty, and creates a new binary log file. (Known as **FLUSH MASTER** in versions of MySQL before 3.23.26.) See [Section 12.6.1, “SQL Statements for Controlling Master Servers”](#).

- **QUERY CACHE**

Removes all query results from the query cache.

- **SLAVE**

Makes the slave forget its replication position in the master binary logs. Also resets the relay log by deleting any existing relay log files and beginning a new one. (Known as **FLUSH SLAVE** in versions of MySQL before 3.23.26.) See [Section 12.6.2, “SQL Statements for Controlling Slave Servers”](#).

12.6. Replication Statements

This section describes SQL statements related to replication. One group of statements is used for controlling master servers. The other is used for controlling slave servers.

12.6.1. SQL Statements for Controlling Master Servers

Replication can be controlled through the SQL interface. This section discusses statements for managing master replication servers. [Section 12.6.2, “SQL Statements for Controlling Slave Servers”](#), discusses statements for managing slave servers.

12.6.1.1. PURGE MASTER LOGS Syntax

```
PURGE {MASTER | BINARY} LOGS TO 'log_name'
PURGE {MASTER | BINARY} LOGS BEFORE 'date'
```

Deletes all the binary logs listed in the log index prior to the specified log or date. The logs also are removed from the list recorded in the log index file, so that the given log becomes the first.

Example:

```
PURGE MASTER LOGS TO 'mysql-bin.010';
PURGE MASTER LOGS BEFORE '2003-04-02 22:46:26';
```

The **BEFORE** variant's *date* argument can be in 'YYYY-MM-DD hh:mm:ss' format. **MASTER** and **BINARY** are synonyms.

This statement is safe to run while slaves are replicating. You do not need to stop them. If you have an active slave that currently is reading one of the logs you are trying to delete, this statement does nothing and fails with an error. However, if a slave is dormant and you happen to purge one of the logs it has yet to read, the slave will be unable to replicate after it comes up.

To safely purge logs, follow this procedure:

1. On each slave server, use **SHOW SLAVE STATUS** to check which log it is reading.
2. Obtain a listing of the binary logs on the master server with **SHOW BINARY LOGS**.
3. Determine the earliest log among all the slaves. This is the target log. If all the slaves are up to date, this is the last log on the list.
4. Make a backup of all the logs you are about to delete. (This step is optional, but always advisable.)
5. Purge all logs up to but not including the target log.

You can also set the `expire_logs_days` system variable to expire binary log files automatically after a given number of days (see [Section 5.2.3, “System Variables”](#)). If you are using replication, you should set the variable no lower than the maximum number of days your slaves might lag behind the master.

12.6.1.2. RESET MASTER Syntax

```
RESET MASTER
```

Deletes all binary logs listed in the index file, resets the binary log index file to be empty, and creates a new binary log file.

12.6.1.3. SET SQL_LOG_BIN Syntax

```
SET SQL_LOG_BIN = {0|1}
```

Disables or enables binary logging for the current connection (`SQL_LOG_BIN` is a session variable) if the client has the **SUPER** privilege. The statement is refused with an error if the client does not have that privilege.

12.6.1.4. SHOW BINLOG EVENTS Syntax

```
SHOW BINLOG EVENTS
[IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
```

Shows the events in the binary log. If you do not specify 'log_name', the first binary log is displayed.

The **LIMIT** clause has the same syntax as for the **SELECT** statement. See [Section 12.2.7, “SELECT Syntax”](#).

Note

Issuing a `SHOW BINLOG EVENTS` with no `LIMIT` clause could start a very time- and resource-consuming process because the server returns to the client the complete contents of the binary log (which includes all statements executed by the server that modify data). As an alternative to `SHOW BINLOG EVENTS`, use the `mysqlbinlog` utility to save the binary log to a text file for later examination and analysis. See [Section 7.11, “mysqlbinlog — Utility for Processing Binary Log Files”](#).

Note

Events relating to the setting of variables is not included in the output generated when calling `SHOW BINLOG EVENTS`. To get complete coverage of events within a binary log, use `mysqlbinlog`.

12.6.1.5. SHOW BINARY LOGS Syntax

```
SHOW BINARY LOGS
SHOW MASTER LOGS
```

Lists the binary log files on the server. This statement is used as part of the procedure described in [Section 12.6.1.1, “PURGE MASTER LOGS Syntax”](#), that shows how to determine which logs can be purged.

```
mysql> SHOW BINARY LOGS;
+-----+-----+
| Log_name | File_size |
+-----+-----+
| binlog.000015 | 724935 |
| binlog.000016 | 733481 |
+-----+-----+
```

`SHOW MASTER LOGS` is equivalent to `SHOW BINARY LOGS`.

12.6.1.6. SHOW MASTER STATUS Syntax

```
SHOW MASTER STATUS
```

Provides status information about the binary log files of the master. Example:

```
mysql > SHOW MASTER STATUS;
+-----+-----+-----+-----+
| File | Position | Binlog_Do_DB | Binlog_Ignore_DB |
+-----+-----+-----+-----+
| mysql-bin.003 | 73 | test | manual,mysql |
+-----+-----+-----+-----+
```

12.6.1.7. SHOW SLAVE HOSTS Syntax

```
SHOW SLAVE HOSTS
```

Displays a list of replication slaves currently registered with the master. Only slaves started with the `--report-host=slave_name` option are visible in this list.

The list is displayed on any server (not just the master server). The output looks like this:

```
mysql> SHOW SLAVE HOSTS;
+-----+-----+-----+-----+
| Server_id | Host | Port | Master_id |
+-----+-----+-----+-----+
| 192168010 | iconnect2 | 3306 | 192168011 |
| 1921680101 | athena | 3306 | 192168011 |
+-----+-----+-----+-----+
```

- **Server_id**: The unique server ID of the slave server, as configured in the server's option file, or on the command line with `--server-id=value`.
- **Host**: The host name of the slave server, as configured in the server's option file, or on the command line with `--report-host=value`. Note that this can differ from the machine name as configured in the operating system.

- **Port**: The port the slave server is listening on.
- **Master_id**: The unique server ID of the master server that the slave server is replicating from.

Some MySQL versions report another variable, `Rpl_recovery_rank`. This variable was never used, and was eventually removed.

12.6.2. SQL Statements for Controlling Slave Servers

Replication can be controlled through the SQL interface. This section discusses statements for managing slave replication servers. [Section 12.6.1, “SQL Statements for Controlling Master Servers”](#), discusses statements for managing master servers.

12.6.2.1. CHANGE MASTER TO Syntax

```
CHANGE MASTER TO master_def [, master_def] ...
```

```
master_def:
MASTER_HOST = 'host_name'
MASTER_USER = 'user_name'
MASTER_PASSWORD = 'password'
MASTER_PORT = port_num
MASTER_CONNECT_RETRY = count
MASTER_LOG_FILE = 'master_log_name'
MASTER_LOG_POS = master_log_pos
RELAY_LOG_FILE = 'relay_log_name'
RELAY_LOG_POS = relay_log_pos
MASTER_SSL = {0|1}
MASTER_SSL_CA = 'ca_file_name'
MASTER_SSL_CAPATH = 'ca_directory_name'
MASTER_SSL_CERT = 'cert_file_name'
MASTER_SSL_KEY = 'key_file_name'
MASTER_SSL_CIPHER = 'cipher_list'
MASTER_SSL_VERIFY_SERVER_CERT = {0|1}
```

CHANGE MASTER TO changes the parameters that the slave server uses for connecting to and communicating with the master server. It also updates the contents of the `master.info` and `relay-log.info` files.

`MASTER_USER`, `MASTER_PASSWORD`, `MASTER_SSL`, `MASTER_SSL_CA`, `MASTER_SSL_CAPATH`, `MASTER_SSL_CERT`, `MASTER_SSL_KEY`, `MASTER_SSL_CIPHER`, and `MASTER_SSL_VERIFY_SERVER_CERT` provide information to the slave about how to connect to its master. `MASTER_SSL_VERIFY_SERVER_CERT` was added in MySQL 5.1.18. It is used as described for the `-ssl-verify-server-cert` option in [Section 5.8.7.3, “SSL Command Options”](#).

The SSL options (`MASTER_SSL`, `MASTER_SSL_CA`, `MASTER_SSL_CAPATH`, `MASTER_SSL_CERT`, `MASTER_SSL_KEY`, `MASTER_SSL_CIPHER`), and `MASTER_SSL_VERIFY_SERVER_CERT` can be changed even on slaves that are compiled without SSL support. They are saved to the `master.info` file, but are ignored unless you use a server that has SSL support enabled.

If you don't specify a given parameter, it keeps its old value, except as indicated in the following discussion. For example, if the password to connect to your MySQL master has changed, you just need to issue these statements to tell the slave about the new password:

```
STOP SLAVE; -- if replication was running
CHANGE MASTER TO MASTER_PASSWORD='new3cret';
START SLAVE; -- if you want to restart replication
```

There is no need to specify the parameters that do not change (host, port, user, and so forth).

`MASTER_HOST` and `MASTER_PORT` are the hostname (or IP address) of the master host and its TCP/IP port. Note that if `MASTER_HOST` is equal to `localhost`, then, like in other parts of MySQL, the port number might be ignored (if Unix socket files can be used, for example).

If you specify `MASTER_HOST` or `MASTER_PORT`, the slave assumes that the master server is different from before (even if you specify a host or port value that is the same as the current value.) In this case, the old values for the master binary log name and position are considered no longer applicable, so if you do not specify `MASTER_LOG_FILE` and `MASTER_LOG_POS` in the statement, `MASTER_LOG_FILE=''` and `MASTER_LOG_POS=4` are silently appended to it.

`MASTER_LOG_FILE` and `MASTER_LOG_POS` are the coordinates at which the slave I/O thread should begin reading from the master the next time the thread starts. If you specify either of them, you cannot specify `RELAY_LOG_FILE` or `RELAY_LOG_POS`. If neither of `MASTER_LOG_FILE` or `MASTER_LOG_POS` are specified, the slave uses the last coordinates of the *slave SQL thread* before **CHANGE MASTER** was issued. This ensures that there is no discontinuity in replication, even if the slave SQL thread was late compared to the slave I/O thread, when you merely want to change, say, the password to use.

CHANGE MASTER *deletes all relay log files* and starts a new one, unless you specify **RELAY_LOG_FILE** or **RELAY_LOG_POS**. In that case, relay logs are kept; the **relay_log_purge** global variable is set silently to 0.

CHANGE MASTER is useful for setting up a slave when you have the snapshot of the master and have recorded the log and the offset corresponding to it. After loading the snapshot into the slave, you can run **CHANGE MASTER TO MASTER_LOG_FILE='log_name_on_master', MASTER_LOG_POS=log_offset_on_master** on the slave.

The following example changes the master and master's binary log coordinates. This is used when you want to set up the slave to replicate the master:

```
CHANGE MASTER TO
  MASTER_HOST='master2.mycompany.com',
  MASTER_USER='replication',
  MASTER_PASSWORD='bigs3cret',
  MASTER_PORT=3306,
  MASTER_LOG_FILE='master2-bin.001',
  MASTER_LOG_POS=4,
  MASTER_CONNECT_RETRY=10;
```

The next example shows an operation that is less frequently employed. It is used when the slave has relay logs that you want it to execute again for some reason. To do this, the master need not be reachable. You need only use **CHANGE MASTER TO** and start the SQL thread (**START SLAVE SQL_THREAD**):

```
CHANGE MASTER TO
  RELAY_LOG_FILE='slave-relay-bin.006',
  RELAY_LOG_POS=4025;
```

You can even use the second operation in a non-replication setup with a standalone, non-slave server for recovery following a crash. Suppose that your server has crashed and you have restored a backup. You want to replay the server's own binary logs (not relay logs, but regular binary logs), named (for example) **myhost-bin.***. First, make a backup copy of these binary logs in some safe place, in case you don't exactly follow the procedure below and accidentally have the server purge the binary logs. Use **SET GLOBAL relay_log_purge=0** for additional safety. Then start the server without the **--log-bin** option. Instead, use the **--replicate-same-server-id**, **--relay-log=myhost-bin** (to make the server believe that these regular binary logs are relay logs) and **--skip-slave-start** options. After the server starts, issue these statements:

```
CHANGE MASTER TO
  RELAY_LOG_FILE='myhost-bin.153',
  RELAY_LOG_POS=410,
  MASTER_HOST='some_dummy_string';
START SLAVE SQL_THREAD;
```

The server reads and executes its own binary logs, thus achieving crash recovery. Once the recovery is finished, run **STOP SLAVE**, shut down the server, delete the **master.info** and **relay-log.info** files, and restart the server with its original options.

Specifying the **MASTER_HOST** option (even with a dummy value) is required to make the server think it is a slave.

12.6.2.2. LOAD DATA FROM MASTER Syntax

```
LOAD DATA FROM MASTER
```

This feature is deprecated. We recommend not using it anymore. It is subject to removal in a future version of MySQL.

Since the current implementation of **LOAD DATA FROM MASTER** and **LOAD TABLE FROM MASTER** is very limited, these statements are deprecated in versions 4.1 of MySQL and above. We will introduce a more advanced technique (called “online backup”) in a future version. That technique will have the additional advantage of working with more storage engines.

For MySQL 5.1 and earlier, the recommended alternative solution to using **LOAD DATA FROM MASTER** or **LOAD TABLE FROM MASTER** is using **mysqldump** or **mysqlhotcopy**. The latter requires Perl and two Perl modules (**DBI** and **DBD:mysql**) and works for **MyISAM** and **ARCHIVE** tables only. With **mysqldump**, you can create SQL dumps on the master and pipe (or copy) these to a **mysql** client on the slave. This has the advantage of working for all storage engines, but can be quite slow, since it works using **SELECT**.

This statement takes a snapshot of the master and copies it to the slave. It updates the values of **MASTER_LOG_FILE** and **MASTER_LOG_POS** so that the slave starts replicating from the correct position. Any table and database exclusion rules specified with the **--replicate-*-do-*** and **--replicate-*-ignore-*** options are honored. **--replicate-rewrite-db** is *not* taken into account because a user could use this option to set up a non-unique mapping such as **--replicate-rewrite-db="db1->db3"** and **--replicate-rewrite-db="db2->db3"**, which would confuse the slave when loading tables from the master.

Use of this statement is subject to the following conditions:

- It works only for **MyISAM** tables. Attempting to load a non-**MyISAM** table results in the following error:

```
ERROR 1189 (08S01): Net error reading from master
```

- It acquires a global read lock on the master while taking the snapshot, which prevents updates on the master during the load operation.

If you are loading large tables, you might have to increase the values of `net_read_timeout` and `net_write_timeout` on both the master and slave servers. See [Section 5.2.3, “System Variables”](#).

Note that **LOAD DATA FROM MASTER** does *not* copy any tables from the **mysql** database. This makes it easy to have different users and privileges on the master and the slave.

To use **LOAD DATA FROM MASTER**, the replication account that is used to connect to the master must have the **RELOAD** and **SUPER** privileges on the master and the **SELECT** privilege for all master tables you want to load. All master tables for which the user does not have the **SELECT** privilege are ignored by **LOAD DATA FROM MASTER**. This is because the master hides them from the user: **LOAD DATA FROM MASTER** calls **SHOW DATABASES** to know the master databases to load, but **SHOW DATABASES** returns only databases for which the user has some privilege. See [Section 12.5.4.12, “SHOW DATABASES Syntax”](#). On the slave side, the user that issues **LOAD DATA FROM MASTER** must have privileges for dropping and creating the databases and tables that are copied.

12.6.2.3. **LOAD TABLE *tbl_name* FROM MASTER** Syntax

```
LOAD TABLE tbl_name FROM MASTER
```

This feature is deprecated. We recommend not using it anymore. It is subject to removal in a future version of MySQL.

Since the current implementation of **LOAD DATA FROM MASTER** and **LOAD TABLE FROM MASTER** is very limited, these statements are deprecated in versions 4.1 of MySQL and above. We will introduce a more advanced technique (called “online backup”) in a future version. That technique will have the additional advantage of working with more storage engines.

For MySQL 5.1 and earlier, the recommended alternative solution to using **LOAD DATA FROM MASTER** or **LOAD TABLE FROM MASTER** is using **mysqldump** or **mysqlhotcopy**. The latter requires Perl and two Perl modules (**DBI** and **DBD:mysql**) and works for **MyISAM** and **ARCHIVE** tables only. With **mysqldump**, you can create SQL dumps on the master and pipe (or copy) these to a **mysql** client on the slave. This has the advantage of working for all storage engines, but can be quite slow, since it works using **SELECT**.

Transfers a copy of the table from the master to the slave. This statement is implemented mainly debugging **LOAD DATA FROM MASTER** operations. To use **LOAD TABLE**, the account used for connecting to the master server must have the **RELOAD** and **SUPER** privileges on the master and the **SELECT** privilege for the master table to load. On the slave side, the user that issues **LOAD TABLE FROM MASTER** must have privileges for dropping and creating the table.

The conditions for **LOAD DATA FROM MASTER** apply here as well. For example, **LOAD TABLE FROM MASTER** works only for **MyISAM** tables. The timeout notes for **LOAD DATA FROM MASTER** apply as well.

12.6.2.4. **MASTER_POS_WAIT()** Syntax

```
SELECT MASTER_POS_WAIT('master_log_file', master_log_pos)
```

This is actually a function, not a statement. It is used to ensure that the slave has read and executed events up to a given position in the master's binary log. See [Section 11.11.4, “Miscellaneous Functions”](#), for a full description.

12.6.2.5. **RESET SLAVE** Syntax

```
RESET SLAVE
```

RESET SLAVE makes the slave forget its replication position in the master's binary logs. This statement is meant to be used for a clean start: It deletes the `master.info` and `relay-log.info` files, all the relay logs, and starts a new relay log.

Note

All relay logs are deleted, even if they have not been completely executed by the slave SQL thread. (This is a condition likely to exist on a replication slave if you have issued a **STOP SLAVE** statement or if the slave is highly loaded.)

Connection information stored in the `master.info` file is immediately reset using any values specified in the corresponding startup options. This information includes values such as master host, master port, master user, and master password. If the slave SQL thread was in the middle of replicating temporary tables when it was stopped, and **RESET SLAVE** is issued, these replicated temporary tables are deleted on the slave.

12.6.2.6. SET GLOBAL SQL_SLAVE_SKIP_COUNTER Syntax

```
SET GLOBAL SQL_SLAVE_SKIP_COUNTER = N
```

This statement skips the next *N* events from the master. This is useful for recovering from replication stops caused by a statement.

This statement is valid only when the slave thread is not running. Otherwise, it produces an error.

12.6.2.7. SHOW SLAVE STATUS Syntax

```
SHOW SLAVE STATUS
```

This statement provides status information on essential parameters of the slave threads. If you issue this statement using the `mysql` client, you can use a `\G` statement terminator rather than a semicolon to obtain a more readable vertical layout:

```
mysql> SHOW SLAVE STATUS\G
***** 1. row *****
      Slave_IO_State: Waiting for master to send event
        Master_Host: localhost
        Master_User: root
        Master_Port: 3306
        Connect_Retry: 3
        Master_Log_File: gbichot-bin.005
        Read_Master_Log_Pos: 79
        Relay_Log_File: gbichot-relay-bin.005
        Relay_Log_Pos: 548
        Relay_Master_Log_File: gbichot-bin.005
        Slave_IO_Running: Yes
        Slave_SQL_Running: Yes
        Replicate_Do_DB:
        Replicate_Ignore_DB:
          Last_Errno: 0
          Last_Error:
          Skip_Counter: 0
        Exec_Master_Log_Pos: 79
        Relay_Log_Space: 552
        Until_Condition: None
        Until_Log_File:
        Until_Log_Pos: 0
        Master_SSL_Allowed: No
        Master_SSL_CA_File:
        Master_SSL_CA_Path:
        Master_SSL_Cert:
        Master_SSL_Cipher:
        Master_SSL_Key:
        Seconds_Behind_Master: 8
Master_SSL_Verify_Server_Cert: No
          Last_IO_Errno: 0
          Last_IO_Error:
          Last_SQL_Errno: 0
          Last_SQL_Error:
```

SHOW SLAVE STATUS returns the following fields:

- **Slave_IO_State**

A copy of the **State** field of the output of **SHOW PROCESSLIST** for the slave I/O thread. This tells you what the thread is doing: trying to connect to the master, waiting for events from the master, reconnecting to the master, and so on. Possible states are listed in [Section 15.4.1, “Replication Implementation Details”](#). It is necessary to check this field for older versions of MySQL which allowed the thread to continue running while unsuccessfully trying to connect to the master. If it is running, there is no problem; if it is not, you can find the error in the **Last_Error** field (described below).

- **Master_Host**

The current master host.

- **Master_User**

The current user used to connect to the master.

- **Master_Port**

The current master port.

- **Connect_Retry**

The current value of the `--master-connect-retry` option.

- **Master_Log_File**

The name of the master binary log file from which the I/O thread is currently reading.

- **Read_Master_Log_Pos**

The position up to which the I/O thread has read in the current master binary log.

- **Relay_Log_File**

The name of the relay log file from which the SQL thread is currently reading and executing.

- **Relay_Log_Pos**

The position up to which the SQL thread has read and executed in the current relay log.

- **Relay_Master_Log_File**

The name of the master binary log file containing the most recent event executed by the SQL thread.

- **Slave_IO_Running**

Whether the I/O thread is started and has connected successfully to the master. For older versions of MySQL (prior to 4.1.14 and 5.0.12) **Slave_IO_Running** is **YES** if the I/O thread is started, even if the slave hasn't connected to the master yet.

- **Slave_SQL_Running**

Whether the SQL thread is started.

- **Replicate_Do_DB, Replicate_Ignore_DB**

The lists of databases that were specified with the `--replicate-do-db` and `--replicate-ignore-db` options, if any.

- **Replicate_Do_Table, Replicate_Ignore_Table, Replicate_Wild_Do_Table, Replicate_Wild_Ignore_Table**

The lists of tables that were specified with the `--replicate-do-table`, `--replicate-ignore-table`, `--replicate-wild-do-table`, and `--replicate-wild-ignore-table` options, if any.

- **Last_Errno, Last_Error**

As of MySQL 5.1.20, these columns are aliases for **Last_SQLErrno** and **Last_SQLError**. Before 5.1.20, they indicate the error number and error message returned by the most recently executed query. An error number of 0 and message of the empty string mean “no error.” If the **Last_Error** value is not empty, it also appears as a message in the slave's error log.

- **Skip_Counter**

The most recently used value for **SQL_SLAVE_SKIP_COUNTER**.

- **Exec_Master_Log_Pos**

The position of the last event executed by the SQL thread from the master's binary log (**Relay_Master_Log_File**). (Re-

`lay_Master_Log_File`, `Exec_Master_Log_Pos`) in the master's binary log corresponds to (`Relay_Log_File`, `Relay_Log_Pos`) in the relay log.

- `Relay_Log_Space`

The total combined size of all existing relay logs.

- `Until_Condition`, `Until_Log_File`, `Until_Log_Pos`

The values specified in the `UNTIL` clause of the `START SLAVE` statement.

`Until_Condition` has these values:

- `None` if no `UNTIL` clause was specified
- `Master` if the slave is reading until a given position in the master's binary logs
- `Relay` if the slave is reading until a given position in its relay logs

`Until_Log_File` and `Until_Log_Pos` indicate the log filename and position values that define the point at which the SQL thread stops executing.

- `Master_SSL_Allowed`, `Master_SSL_CA_File`, `Master_SSL_CA_Path`, `Master_SSL_Cert`, `Master_SSL_Cipher`, `Master_SSL_Key`

These fields show the SSL parameters used by the slave to connect to the master, if any.

`Master_SSL_Allowed` has these values:

- `Yes` if an SSL connection to the master is permitted
- `No` if an SSL connection to the master is not permitted
- `Ignored` if an SSL connection is permitted but the slave server does not have SSL support enabled

The values of the other SSL-related fields correspond to the values of the `MASTER_SSL_CA`, `MASTER_SSL_CAPATH`, `MASTER_SSL_CERT`, `MASTER_SSL_CIPHER`, `MASTER_SSL_KEY`, and `MASTER_SSL_VERIFY_SERVER_CERT` options to the `CHANGE MASTER` statement. See [Section 12.6.2.1, “CHANGE MASTER TO Syntax”](#). `MASTER_SSL_VERIFY_SERVER_CERT` was added in MySQL 5.1.18.

- `Seconds_Behind_Master`

This field is an indication of how “late” the slave is:

- When the slave SQL thread is actively running (processing updates), this field is the number of seconds that have elapsed since the timestamp of the most recent event on the master executed by that thread.
- When the SQL thread has caught up to the slave I/O thread and goes idle waiting for more events from the I/O thread, this field is zero.

In essence, this field measures the time difference in seconds between the slave SQL thread and the slave I/O thread.

If the network connection between master and slave is fast, the slave I/O thread is very close to the master, so this field is a good approximation of how late the slave SQL thread is compared to the master. If the network is slow, this is *not* a good approximation; the slave SQL thread may quite often be caught up with the slow-reading slave I/O thread, so `Seconds_Behind_Master` often shows a value of 0, even if the I/O thread is late compared to the master. In other words, *this column is useful only for fast networks*.

This time difference computation works even though the master and slave do not have identical clocks (the clock difference is computed when the slave I/O thread starts, and assumed to remain constant from then on). `Seconds_Behind_Master` is `NULL` (which means “unknown”) if the slave SQL thread is not running, or if the slave I/O thread is not running or not connected to master. For example if the slave I/O thread is sleeping for the number of seconds given by the `--master-connect-retry` option before reconnecting, `NULL` is shown, as the slave cannot know what the master is doing, and so cannot say reliably how late it is.

This field has one limitation. The timestamp is preserved through replication, which means that, if a master M1 is itself a slave of M0, any event from M1's binlog which originates in replicating an event from M0's binlog has the timestamp of that event. This enables MySQL to replicate `TIMESTAMP` successfully. However, the drawback for `Seconds_Behind_Master` is that if M1 also

receives direct updates from clients, the value randomly deviates, because sometimes the last M1's event is from M0 and sometimes it is the most recent timestamp from a direct update.

- **Last_IO_Errno, Last_IO_Error**

The error number and error message of the last error that caused the I/O thread to stop. An error number of 0 and message of the empty string mean “no error.” If the **Last_IO_Error** value is not empty, it also appears as a message in the slave's error log. These columns were added in MySQL 5.1.20.

- **Last_SQL_Errno, Last_SQL_Error**

The error number and error message of the last error that caused the SQL thread to stop. An error number of 0 and message of the empty string mean “no error.” If the **Last_IO_Error** value is not empty, it also appears as a message in the slave's error log. These columns were added in MySQL 5.1.20.

Example:

```
Last_SQL_Errno: 1051
Last_SQL_Error: error 'Unknown table 'z'' on query 'drop table z'
```

The message indicates that the table **z** existed on the master and was dropped there, but it did not exist on the slave, so **DROP TABLE** failed on the slave. (This might occur, for example, if you forget to copy the table to the slave when setting up replication.)

12.6.2.8. START SLAVE Syntax

```
START SLAVE [thread_type [, thread_type] ... ]
START SLAVE [SQL_THREAD] UNTIL
  MASTER_LOG_FILE = 'log_name', MASTER_LOG_POS = log_pos
START SLAVE [SQL_THREAD] UNTIL
  RELAY_LOG_FILE = 'log_name', RELAY_LOG_POS = log_pos

thread_type: IO_THREAD | SQL_THREAD
```

START SLAVE with no *thread_type* options starts both of the slave threads. The I/O thread reads queries from the master server and stores them in the relay log. The SQL thread reads the relay log and executes the queries. **START SLAVE** requires the **SUPER** privilege.

If **START SLAVE** succeeds in starting the slave threads, it returns without any error. However, even in that case, it might be that the slave threads start and then later stop (for example, because they do not manage to connect to the master or read its binary logs, or some other problem). **START SLAVE** does not warn you about this. You must check the slave's error log for error messages generated by the slave threads, or check that they are running satisfactorily with **SHOW SLAVE STATUS**.

You can add **IO_THREAD** and **SQL_THREAD** options to the statement to name which of the threads to start.

An **UNTIL** clause may be added to specify that the slave should start and run until the SQL thread reaches a given point in the master binary logs or in the slave relay logs. When the SQL thread reaches that point, it stops. If the **SQL_THREAD** option is specified in the statement, it starts only the SQL thread. Otherwise, it starts both slave threads. If the SQL thread is running, the **UNTIL** clause is ignored and a warning is issued.

For an **UNTIL** clause, you must specify both a log filename and position. Do not mix master and relay log options.

Any **UNTIL** condition is reset by a subsequent **STOP SLAVE** statement, a **START SLAVE** statement that includes no **UNTIL** clause, or a server restart.

The **UNTIL** clause can be useful for debugging replication, or to cause replication to proceed until just before the point where you want to avoid having the slave replicate a statement. For example, if an unwise **DROP TABLE** statement was executed on the master, you can use **UNTIL** to tell the slave to execute up to that point but no farther. To find what the event is, use **mysqlbinlog** with the master logs or slave relay logs, or by using a **SHOW BINLOG EVENTS** statement.

If you are using **UNTIL** to have the slave process replicated queries in sections, it is recommended that you start the slave with the **-skip-slave-start** option to prevent the SQL thread from running when the slave server starts. It is probably best to use this option in an option file rather than on the command line, so that an unexpected server restart does not cause it to be forgotten.

The **SHOW SLAVE STATUS** statement includes output fields that display the current values of the **UNTIL** condition.

In old versions of MySQL (before 4.0.5), this statement was called **SLAVE START**. This usage is still accepted in MySQL 5.1 for backward compatibility, but is deprecated.

12.6.2.9. STOP SLAVE Syntax

```
STOP SLAVE [thread_type [, thread_type] ... ]  
thread_type: IO_THREAD | SQL_THREAD
```

Stops the slave threads. **STOP SLAVE** requires the **SUPER** privilege.

Like **START SLAVE**, this statement may be used with the **IO_THREAD** and **SQL_THREAD** options to name the thread or threads to be stopped.

In old versions of MySQL (before 4.0.5), this statement was called **SLAVE STOP**. This usage is still accepted in MySQL 5.1 for backward compatibility, but is deprecated.

12.7. SQL Syntax for Prepared Statements

MySQL 5.1 provides support for server-side prepared statements. This support takes advantage of the efficient client/server binary protocol implemented in MySQL 4.1, provided that you use an appropriate client programming interface. Candidate interfaces include the MySQL C API client library (for C programs), MySQL Connector/J (for Java programs), and MySQL Connector/NET. For example, the C API provides a set of function calls that make up its prepared statement API. See [Section 25.2.4, “C API Prepared Statements”](#). Other language interfaces can provide support for prepared statements that use the binary protocol by linking in the C client library, one example being the [mysql extension](#), available in PHP 5.0 and later.

An alternative SQL interface to prepared statements is available. This interface is not as efficient as using the binary protocol through a prepared statement API, but requires no programming because it is available directly at the SQL level:

- You can use it when no programming interface is available to you.
- You can use it from any program that allows you to send SQL statements to the server to be executed, such as the [mysql](#) client program.
- You can use it even if the client is using an old version of the client library. The only requirement is that you be able to connect to a server that is recent enough to support SQL syntax for prepared statements.

SQL syntax for prepared statements is intended to be used for situations such as these:

- You want to test how prepared statements work in your application before coding it.
- An application has problems executing prepared statements and you want to determine interactively what the problem is.
- You want to create a test case that describes a problem you are having with prepared statements, so that you can file a bug report.
- You need to use prepared statements but do not have access to a programming API that supports them.

SQL syntax for prepared statements is based on three SQL statements:

- **PREPARE** *stmt_name* **FROM** *preparable_stmt*

The **PREPARE** statement prepares a statement and assigns it a name, *stmt_name*, by which to refer to the statement later. Statement names are not case sensitive. *preparable_stmt* is either a string literal or a user variable that contains the text of the statement. The text must represent a single SQL statement, not multiple statements. Within the statement, ‘?’ characters can be used as parameter markers to indicate where data values are to be bound to the query later when you execute it. The ‘?’ characters should not be enclosed within quotes, even if you intend to bind them to string values. Parameter markers can be used only where data values should appear, not for SQL keywords, identifiers, and so forth.

If a prepared statement with the given name already exists, it is deallocated implicitly before the new statement is prepared. This means that if the new statement contains an error and cannot be prepared, an error is returned and no statement with the given name

exists.

The scope of a prepared statement is the client session within which it is created. Other clients cannot see it.

- `EXECUTE stmt_name [USING @var_name [, @var_name] ...]`

After preparing a statement, you execute it with an `EXECUTE` statement that refers to the prepared statement name. If the prepared statement contains any parameter markers, you must supply a `USING` clause that lists user variables containing the values to be bound to the parameters. Parameter values can be supplied only by user variables, and the `USING` clause must name exactly as many variables as the number of parameter markers in the statement.

You can execute a given prepared statement multiple times, passing different variables to it or setting the variables to different values before each execution.

- `{DEALLOCATE | DROP} PREPARE stmt_name`

To deallocate a prepared statement, use the `DEALLOCATE PREPARE` statement. Attempting to execute a prepared statement after deallocating it results in an error.

If you terminate a client session without deallocating a previously prepared statement, the server deallocates it automatically.

The following SQL statements can be used in prepared statements: `CREATE TABLE`, `DELETE`, `DO`, `INSERT`, `REPLACE`, `SELECT`, `SET`, `UPDATE`, and most `SHOW` statements.

As of MySQL 5.1.10, the following additional statements are supported:

```
ANALYZE TABLE
OPTIMIZE TABLE
REPAIR TABLE
```

As of MySQL 5.1.12, the following additional statements are supported:

```
CACHE INDEX
CHANGE MASTER
CHECKSUM {TABLE | TABLES}
{CREATE | RENAME | DROP} DATABASE
{CREATE | RENAME | DROP} USER
FLUSH {TABLE | TABLES | TABLES WITH READ LOCK | HOSTS | PRIVILEGES
      | LOGS | STATUS | MASTER | SLAVE | DES_KEY_FILE | USER_RESOURCES}
GRANT
REVOKE
KILL
LOAD INDEX INTO CACHE
RESET {MASTER | SLAVE | QUERY CACHE}
SHOW BINLOG EVENTS
SHOW CREATE {PROCEDURE | FUNCTION | EVENT | TABLE | VIEW}
SHOW {AUTHORS | CONTRIBUTORS | WARNINGS | ERRORS}
SHOW {MASTER | BINARY} LOGS
SHOW {MASTER | SLAVE} STATUS
SLAVE {START | STOP}
INSTALL PLUGIN
UNINSTALL PLUGIN
```

Other statements are not yet supported.

Statements not allowed in SQL prepared statements are generally also not permitted in stored routines. Any exceptions to this rule are noted in [Chapter 19, Stored Procedures and Functions](#).

The following examples show two equivalent ways of preparing a statement that computes the hypotenuse of a triangle given the lengths of the two sides.

The first example shows how to create a prepared statement by using a string literal to supply the text of the statement:

```
mysql> PREPARE stmt1 FROM 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
mysql> SET @a = 3;
mysql> SET @b = 4;
mysql> EXECUTE stmt1 USING @a, @b;
+-----+
| hypotenuse |
+-----+
|          5 |
```

```
+-----+
mysql> DEALLOCATE PREPARE stmt1;
```

The second example is similar, but supplies the text of the statement as a user variable:

```
mysql> SET @s = 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
mysql> PREPARE stmt2 FROM @s;
mysql> SET @a = 6;
mysql> SET @b = 8;
mysql> EXECUTE stmt2 USING @a, @b;
+-----+
| hypotenuse |
+-----+
|          10 |
+-----+
mysql> DEALLOCATE PREPARE stmt2;
```

Placeholders can be used for the arguments of the [LIMIT](#) clause when using prepared statements. See [Section 12.2.7, “SELECT Syntax”](#).

SQL syntax for prepared statements cannot be used in nested fashion. That is, a statement passed to [PREPARE](#) cannot itself be a [PREPARE](#), [EXECUTE](#), or [DEALLOCATE PREPARE](#) statement.

SQL syntax for prepared statements is distinct from using prepared statement API calls. For example, you cannot use the [mysql_stmt_prepare\(\)](#) C API function to prepare a [PREPARE](#), [EXECUTE](#), or [DEALLOCATE PREPARE](#) statement.

SQL syntax for prepared statements can be used within stored procedures, but not in stored functions or triggers. However, a cursor cannot be used for a dynamic statement that is prepared and executed with [PREPARE](#) and [EXECUTE](#). The statement for a cursor is checked at cursor creation time, so the statement cannot be dynamic.

SQL syntax for prepared statements does not support multi-statements (that is, multiple statements within a single string separated by `;` characters).

Before MySQL 5.1.17, prepared statements do not use the query cache. As of 5.1.17, prepared statements use the query cache under the conditions described in [Section 6.5.4.1, “How the Query Cache Operates”](#).

Chapter 13. Storage Engines

MySQL supports several storage engines that act as handlers for different table types. MySQL storage engines include both those that handle transaction-safe tables and those that handle non-transaction-safe tables:

With MySQL 5.1, MySQL AB has introduced a new pluggable storage engine architecture that allows storage engines to be loaded into and unloaded from a running MySQL server.

This chapter describes each of the MySQL storage engines except for **NDB Cluster**, which is covered in [Chapter 16, MySQL Cluster](#). It also contains a description of the pluggable storage engine architecture (see [Section 13.1, “Overview of MySQL Storage Engine Architecture”](#)).

For answers to some commonly asked questions about MySQL storage engines, see [Section A.2, “MySQL 5.1 FAQ — Storage Engines”](#).

13.1. Overview of MySQL Storage Engine Architecture

The MySQL pluggable storage engine architecture allows a database professional to select a specialized storage engine for a particular application need while being completely shielded from the need to manage any specific application coding requirements. The MySQL server architecture isolates the application programmer and DBA from all of the low-level implementation details at the storage level, providing a consistent and easy application model and API. Thus, although there are different capabilities across different storage engines, the application is shielded from these differences.

The MySQL pluggable storage engine architecture is shown in [Figure 13.1, “The MySQL architecture using pluggable storage engines”](#).

Figure 13.1. The MySQL architecture using pluggable storage engines

The pluggable storage engine architecture provides a standard set of management and support services that are common among all underlying storage engines. The storage engines themselves are the components of the database server that actually perform actions on the underlying data that is maintained at the physical server level.

This efficient and modular architecture provides huge benefits for those wishing to specifically target a particular application need — such as data warehousing, transaction processing, or high availability situations — while enjoying the advantage of utilizing a set of interfaces and services that are independent of any one storage engine.

The application programmer and DBA interact with the MySQL database through Connector APIs and service layers that are above the storage engines. If application changes bring about requirements that demand the underlying storage engine change, or that one or more additional storage engines be added to support new needs, no significant coding or process changes are required to make things work. The MySQL server architecture shields the application from the underlying complexity of the storage engine by presenting a consistent and easy-to-use API that applies across storage engines.

13.1.1. The Common Database Server Layer

A MySQL pluggable storage engine is the component in the MySQL database server that is responsible for performing the actual data I/O operations for a database as well as enabling and enforcing certain feature sets that target a specific application need. A major benefit of using specific storage engines is that you are only delivered the features needed for a particular application, and therefore you have less system overhead in the database, with the end result being more efficient and higher database performance. This is one of the reasons that MySQL has always been known to have such high performance, matching or beating proprietary monolithic databases in industry standard benchmarks.

From a technical perspective, what are some of the unique supporting infrastructure components that are in a storage engine? Some of the key feature differentiations include:

- *Concurrency* — some applications have more granular lock requirements (such as row-level locks) than others. Choosing the right locking strategy can reduce overhead and therefore improve overall performance. This area also includes support for capabilities such as multi-version concurrency control or “snapshot” read.
- *Transaction Support* — Not every application needs transactions, but for those that do, there are very well defined requirements such as ACID compliance and more.
- *Referential Integrity* — The need to have the server enforce relational database referential integrity through DDL defined foreign keys.
- *Physical Storage* — This involves everything from the overall page size for tables and indexes as well as the format used for storing data to physical disk.
- *Index Support* — Different application scenarios tend to benefit from different index strategies. Each storage engine generally has its own indexing methods, although some (such as B-tree indexes) are common to nearly all engines.
- *Memory Caches* — Different applications respond better to some memory caching strategies than others, so although some memory caches are common to all storage engines (such as those used for user connections or MySQL's high-speed Query Cache), others are uniquely defined only when a particular storage engine is put in play.
- *Performance Aids* — This includes multiple I/O threads for parallel operations, thread concurrency, database checkpointing, bulk insert handling, and more.
- *Miscellaneous Target Features* — This may include support for geospatial operations, security restrictions for certain data manipulation operations, and other similar features.

Each set of the pluggable storage engine infrastructure components are designed to offer a selective set of benefits for a particular application. Conversely, avoiding a set of component features helps reduce unnecessary overhead. It stands to reason that understanding a particular application's set of requirements and selecting the proper MySQL storage engine can have a dramatic impact on overall system efficiency and performance.

13.1.2. Pluggable Storage Engine Architecture

With MySQL 5.1, MySQL AB has introduced a new pluggable storage engine architecture that allows storage engines to be loaded into and unloaded from a running MySQL server.

Plugging in a Storage Engine

Before a storage engine can be used, the storage engine plugin shared library must be loaded into MySQL using the `INSTALL PLUGIN` statement. For example, if the `EXAMPLE` engine plugin is named `ha_example` and the shared library is named `ha_example.so`, you load it with the following statement:

```
mysql> INSTALL PLUGIN ha_example SONAME 'ha_example.so';
```

To install a pluggable storage engine, the plugin file must be located in the MySQL plugin directory, and the user issuing the `INSTALL PLUGIN` statement must have `INSERT` privileges for the `mysql.plugin` table.

The shared library must be located in the MySQL server plugin directory, the location of which is given by the `plugin_dir` system variable.

Unplugging a Storage Engine

To unplug a storage engine, use the `UNINSTALL PLUGIN` statement:

```
mysql> UNINSTALL PLUGIN ha_example;
```

If you unplug a storage engine that is needed by existing tables, those tables become inaccessible, but will still be present on disk (where applicable). Ensure that there are no tables using a storage engine before you unplug the storage engine.

13.2. Supported Storage Engines

MySQL 5.1 supports the following storage engines:

- **MyISAM** — The default MySQL storage engine and the one that is used the most in Web, data warehousing, and other application environments. **MyISAM** is supported in all MySQL configurations, and is the default storage engine unless you have configured MySQL to use a different one by default.
- **InnoDB** — Used for transaction processing applications, and sports a number of features including ACID transaction support and foreign keys. **InnoDB** is included by default in all MySQL 5.1 binary distributions. In source distributions, you can enable or disable either engine by configuring MySQL as you like.
- **Memory** — Stores all data in RAM for extremely fast access in environments that require quick lookups of reference and other like data. This engine was formerly known as the **HEAP** engine.
- **Merge** — Allows a MySQL DBA or developer to logically group a series of identical **MyISAM** tables and reference them as one object. Good for VLDB environments such as data warehousing.
- **Archive** — Provides the perfect solution for storing and retrieving large amounts of seldom-referenced historical, archived, or security audit information.
- **Federated** — Offers the ability to link separate MySQL servers to create one logical database from many physical servers. Very good for distributed or data mart environments.
- **NDB** — The Clustered database engine that is particularly suited for applications with high performance lookup needs that also require the highest possible degree of uptime and availability.
- **CSV** — The CSV storage engine stores data in text files using comma-separated values format. You can use the CSV engine to easily exchange data between other software and applications that can import and export in CSV format.
- **Blackhole** — The Blackhole storage engine accepts but does not store data and retrievals always return an empty set. The functionality can be used in distributed database design where data is automatically replicated, but not stored locally.
- **Example** — The Example storage engine is “stub” engine that does nothing. You can create tables with this engine, but no data can be stored in them or retrieved from them. The purpose of this engine is to serve as an example in the MySQL source code that illustrates how to begin writing new storage engines. As such, it is primarily of interest to developers.

This chapter describes each of the MySQL storage engines except for **NDB Cluster**, which is covered in [Chapter 16, MySQL Cluster](#).

It is important to remember that you are not restricted to using the same storage engine for an entire server or schema: you can use a different storage engine for each table in your schema.

13.2.1. Choosing a Storage Engine

The various storage engines provided with MySQL are designed with different use-cases in mind. To use the pluggable storage architecture effectively, it is good to have an idea of the benefits and drawbacks of the various storage engines. The following table provides an overview of some storage engines provided with MySQL:

Feature	MyISAM	Memory	InnoDB	Archive	NDB
Storage limits	256TB	Yes	64TB	No	384EB ^a
Transactions	No	No	Yes	No	Yes
Locking granularity	Table	Table	Row	Row	Row
MVCC (snapshot read)	No	No	Yes	Yes	No
Geospatial datatype support	Yes	No	Yes	Yes	Yes
Geospatial indexing support	Yes	No	No	No	No
B-tree indexes	Yes	Yes	Yes	No	Yes
Hash indexes	No	Yes	No	No	Yes
Full-text search indexes	Yes	No	No	No	No
Clustered indexes	No	No	Yes	No	No
Data caches	No	N/A	Yes	No	Yes
Index caches	Yes	N/A	Yes	No	Yes
Compressed data	Yes ^b	No	No	Yes	No
Encrypted data ^c	Yes	Yes	Yes	Yes	Yes
Cluster database support	No	No	No	No	Yes
Replication support ^d	Yes	Yes	Yes	Yes	Yes
Foreign key support	No	No	Yes	No	No
Backup / point-in-time recovery ^e	Yes	Yes	Yes	Yes	Yes
Query cache support	Yes	Yes	Yes	Yes	Yes
Update statistics for data dictionary	Yes	Yes	Yes	Yes	Yes

^a EB = exabyte (1024 * 1024 terabyte)

^b Compressed MyISAM tables are only supported when using the compressed row format. Tables using the compressed row format with MyISAM are read-only.

^c Implemented in the server (via encryption functions), rather than in the storage engine.

^d Implemented in the server, rather than in the storage engine

^e Implemented in the server, rather than in the storage engine

13.2.2. Comparing Transaction and Non-Transaction Engines

Transaction-safe tables (TSTs) have several advantages over non-transaction-safe tables (NTSTs):

- They are safer. Even if MySQL crashes or you get hardware problems, you can get your data back, either by automatic recovery or from a backup plus the transaction log.
- You can combine many statements and accept them all at the same time with the **COMMIT** statement (if autocommit is disabled).
- You can execute **ROLLBACK** to ignore your changes (if autocommit is disabled).
- If an update fails, all of your changes are reverted. (With non-transaction-safe tables, all changes that have taken place are permanent.)
- Transaction-safe storage engines can provide better concurrency for tables that get many updates concurrently with reads.

You can combine transaction-safe and non-transaction-safe tables in the same statements to get the best of both worlds. However, although MySQL supports several transaction-safe storage engines, for best results, you should not mix different storage engines within a transaction with autocommit disabled. For example, if you do this, changes to non-transaction-safe tables still are committed immedi-

ately and cannot be rolled back. For information about this and other problems that can occur in transactions that use mixed storage engines, see [Section 12.4.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”](#).

Non-transaction-safe tables have several advantages of their own, all of which occur because there is no transaction overhead:

- Much faster
- Lower disk space requirements
- Less memory required to perform updates

13.2.3. Other Storage Engines

Other storage engines may be available from third parties and community members that have used the Custom Storage Engine interface.

You can find more information on the list of third party storage engines on the [MySQL Forge Storage Engines](#) page.

Note

Third party engines are not supported by MySQL. For further information, documentation, installation guides, bug reporting or for any help or assistance with these engines, please contact the developer of the engine directly.

Third party engines that are known to be available include the following; please see the MySQL Forge links provided for more information:

- **PrimeBase XT (PBXT)** — PBXT has been designed for modern, web-based, high concurrency environments.
- **RitmarkFS** — RitmarkFS allows you to access and manipulate the filesystem using SQL queries. RitmarkFS also supports filesystem replication and directory change tracking.
- **Distributed Data Engine** — The Distributed Data Engine is an Open Source project that is dedicated to provide a Storage Engine for distributed data according to workload statistics.
- **mdbtools** — A pluggable storage engine that allows read-only access to Microsoft Access `.mdb` database files.
- **solidDB for MySQL** — solidDB Storage Engine for MySQL is an open source, transactional storage engine for MySQL Server. It is designed for mission-critical implementations that require a robust, transactional database. solidDB Storage Engine for MySQL is a multi-threaded storage engine that supports full ACID compliance with all expected transaction isolation levels, row-level locking, and Multi-Version Concurrency Control (MVCC) with non-blocking reads and writes.

For more information on developing a customer storage engine that can be used with the Pluggable Storage Engine Architecture, see [Writing a Custom Storage Engine](#) on [MySQL Forge](#).

13.3. Setting the Storage Engine

When you create a new table, you can specify which storage engine to use by adding an **ENGINE** table option to the **CREATE TABLE** statement:

```
CREATE TABLE t (i INT) ENGINE = INNODB;
```

If you omit the **ENGINE** or **TYPE** option, the default storage engine is used. Normally, this is **MyISAM**, but you can change it by using the `--default-storage-engine` or `--default-table-type` server startup option, or by setting the `default-storage-engine` or `default-table-type` option in the `my.cnf` configuration file.

You can set the default storage engine to be used during the current session by setting the `storage_engine` variable:

```
SET storage_engine=MYISAM;
```

When MySQL is installed on Windows using the MySQL Configuration Wizard, the **InnoDB** storage engine can be selected as the default instead of **MyISAM**. See [Section 2.3.4.6, “The Database Usage Dialog”](#).

To convert a table from one storage engine to another, use an `ALTER TABLE` statement that indicates the new engine:

```
ALTER TABLE t ENGINE = MYISAM;
```

See [Section 12.1.10, “CREATE TABLE Syntax”](#), and [Section 12.1.4, “ALTER TABLE Syntax”](#).

If you try to use a storage engine that is not compiled in or that is compiled in but deactivated, MySQL instead creates a table using the default storage engine, usually `MyISAM`. This behavior is convenient when you want to copy tables between MySQL servers that support different storage engines. (For example, in a replication setup, perhaps your master server supports transactional storage engines for increased safety, but the slave servers use only non-transactional storage engines for greater speed.)

This automatic substitution of the default storage engine for unavailable engines can be confusing for new MySQL users. A warning is generated whenever a storage engine is automatically changed.

For new tables, MySQL always creates an `.frm` file to hold the table and column definitions. The table's index and data may be stored in one or more other files, depending on the storage engine. The server creates the `.frm` file above the storage engine level. Individual storage engines create any additional files required for the tables that they manage. If a table name contains special characters, the names for the table files contain encoded versions of those characters as described in [Section 8.2.3, “Mapping of Identifiers to File-names”](#).

A database may contain tables of different types. That is, tables need not all be created with the same storage engine.

13.4. The `MyISAM` Storage Engine

`MyISAM` is the default storage engine. It is based on the older `ISAM` code but has many useful extensions. (Note that MySQL 5.1 does *not* support `ISAM`.)

Each `MyISAM` table is stored on disk in three files. The files have names that begin with the table name and have an extension to indicate the file type. An `.frm` file stores the table format. The data file has an `.MYD` (`MYData`) extension. The index file has an `.MYI` (`MYIndex`) extension.

To specify explicitly that you want a `MyISAM` table, indicate that with an `ENGINE` table option:

```
CREATE TABLE t (i INT) ENGINE = MYISAM;
```

Normally, it is unnecessary to use `ENGINE` to specify the `MyISAM` storage engine. `MyISAM` is the default engine unless the default has been changed. To ensure that `MyISAM` is used in situations where the default might have been changed, include the `ENGINE` option explicitly.

You can check or repair `MyISAM` tables with the `mysqlcheck` client or `myisamchk` utility. You can also compress `MyISAM` tables with `myisampack` to take up much less space. See [Section 7.12, “mysqlcheck — A Table Maintenance and Repair Program”](#), [Section 5.9.4.1, “Using myisamchk for Crash Recovery”](#), and [Section 7.7, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#).

`MyISAM` tables have the following characteristics:

- All data values are stored with the low byte first. This makes the data machine and operating system independent. The only requirements for binary portability are that the machine uses two's-complement signed integers and IEEE floating-point format. These requirements are widely used among mainstream machines. Binary compatibility might not be applicable to embedded systems, which sometimes have peculiar processors.

There is no significant speed penalty for storing data low byte first; the bytes in a table row normally are unaligned and it takes little more processing to read an unaligned byte in order than in reverse order. Also, the code in the server that fetches column values is not time critical compared to other code.

- All numeric key values are stored with the high byte first to allow better index compression.
- Large files (up to 63-bit file length) are supported on filesystems and operating systems that support large files.
- There is a limit of 2^{32} (~4.295E+09) rows in a `MyISAM` table. If you build MySQL with the `--with-big-tables` option, the row limitation is increased to $(2^{32})^2$ (1.844E+19) rows. See [Section 2.9.2, “Typical configure Options”](#). Binary distributions for Unix and Linux are built with this option.

- The maximum number of indexes per **MyISAM** table is 64. This can be changed by recompiling. Beginning with MySQL 5.1.4, you can configure the build by invoking **configure** with the **--with-max-indexes=N** option, where *N* is the maximum number of indexes to permit per **MyISAM** table. *N* must be less than or equal to 128. Before MySQL 5.1.4, you must change the source.

The maximum number of columns per index is 16.

- The maximum key length is 1000 bytes. This can also be changed by changing the source and recompiling. For the case of a key longer than 250 bytes, a larger key block size than the default of 1024 bytes is used.
- When rows are inserted in sorted order (as when you are using an **AUTO_INCREMENT** column), the index tree is split so that the high node only contains one key. This improves space utilization in the index tree.
- Internal handling of one **AUTO_INCREMENT** column per table is supported. **MyISAM** automatically updates this column for **INSERT** and **UPDATE** operations. This makes **AUTO_INCREMENT** columns faster (at least 10%). Values at the top of the sequence are not reused after being deleted. (When an **AUTO_INCREMENT** column is defined as the last column of a multiple-column index, reuse of values deleted from the top of a sequence does occur.) The **AUTO_INCREMENT** value can be reset with **ALTER TABLE** or **myisamchk**.
- Dynamic-sized rows are much less fragmented when mixing deletes with updates and inserts. This is done by automatically combining adjacent deleted blocks and by extending blocks if the next block is deleted.
- **MyISAM** supports concurrent inserts: If a table has no free blocks in the middle of the data file, you can **INSERT** new rows into it at the same time that other threads are reading from the table. A free block can occur as a result of deleting rows or an update of a dynamic length row with more data than its current contents. When all free blocks are used up (filled in), future inserts become concurrent again. See [Section 6.3.3, “Concurrent Inserts”](#).
- You can put the data file and index file on different directories to get more speed with the **DATA DIRECTORY** and **INDEX DIRECTORY** table options to **CREATE TABLE**. See [Section 12.1.10, “CREATE TABLE Syntax”](#).
- **BLOB** and **TEXT** columns can be indexed.
- **NULL** values are allowed in indexed columns. This takes 0–1 bytes per key.
- Each character column can have a different character set. See [Chapter 9, Character Set Support](#).
- There is a flag in the **MyISAM** index file that indicates whether the table was closed correctly. If **mysqld** is started with the **-myisam-recover** option, **MyISAM** tables are automatically checked when opened, and are repaired if the table wasn't closed properly.
- **myisamchk** marks tables as checked if you run it with the **--update-state** option. **myisamchk --fast** checks only those tables that don't have this mark.
- **myisamchk --analyze** stores statistics for portions of keys, as well as for entire keys.
- **myisampack** can pack **BLOB** and **VARCHAR** columns.

MyISAM also supports the following features:

- Support for a true **VARCHAR** type; a **VARCHAR** column starts with a length stored in one or two bytes.
- Tables with **VARCHAR** columns may have fixed or dynamic row length.
- The sum of the lengths of the **VARCHAR** and **CHAR** columns in a table may be up to 64KB.
- Arbitrary length **UNIQUE** constraints.

Additional resources

- A forum dedicated to the **MyISAM** storage engine is available at <http://forums.mysql.com/list.php?21>.

13.4.1. **MyISAM** Startup Options

The following options to `mysqld` can be used to change the behavior of `MyISAM` tables. For additional information, see [Section 5.2.2, “Command Options”](#).

- `--myisam-recover=mode`

Set the mode for automatic recovery of crashed `MyISAM` tables.

- `--delay-key-write=ALL`

Don't flush key buffers between writes for any `MyISAM` table.

Note

If you do this, you should not access `MyISAM` tables from another program (such as from another MySQL server or with `myisamchk`) when the tables are in use. Doing so risks index corruption. Using `--external-locking` does not eliminate this risk.

The following system variables affect the behavior of `MyISAM` tables. For additional information, see [Section 5.2.3, “System Variables”](#).

- `bulk_insert_buffer_size`

The size of the tree cache used in bulk insert optimization. **Note:** This is a limit *per thread*!

- `myisam_max_sort_file_size`

The maximum size of the temporary file that MySQL is allowed to use while re-creating a `MyISAM` index (during `REPAIR TABLE`, `ALTER TABLE`, or `LOAD DATA INFILE`). If the file size would be larger than this value, the index is created using the key cache instead, which is slower. The value is given in bytes.

- `myisam_sort_buffer_size`

Set the size of the buffer used when recovering tables.

Automatic recovery is activated if you start `mysqld` with the `--myisam-recover` option. In this case, when the server opens a `MyISAM` table, it checks whether the table is marked as crashed or whether the open count variable for the table is not 0 and you are running the server with external locking disabled. If either of these conditions is true, the following happens:

- The server checks the table for errors.
- If the server finds an error, it tries to do a fast table repair (with sorting and without re-creating the data file).
- If the repair fails because of an error in the data file (for example, a duplicate-key error), the server tries again, this time re-creating the data file.
- If the repair still fails, the server tries once more with the old repair option method (write row by row without sorting). This method should be able to repair any type of error and has low disk space requirements.

MySQL Enterprise

Subscribers to MySQL Enterprise Monitor receive notification if the `--myisam-recover` option has not been set. For more information see <http://www.mysql.com/products/enterprise/advisors.html>.

If the recovery wouldn't be able to recover all rows from previously completed statements and you didn't specify `FORCE` in the value of the `--myisam-recover` option, automatic repair aborts with an error message in the error log:

```
Error: Couldn't repair table: test.g00pages
```

If you specify `FORCE`, a warning like this is written instead:

```
Warning: Found 344 of 354 rows when repairing ./test/g00pages
```

Note that if the automatic recovery value includes [BACKUP](#), the recovery process creates files with names of the form `tbl_name-datetime.BAK`. You should have a [cron](#) script that automatically moves these files from the database directories to backup media.

13.4.2. Space Needed for Keys

[MyISAM](#) tables use B-tree indexes. You can roughly calculate the size for the index file as $(key\_length+4)/0.67$, summed over all keys. This is for the worst case when all keys are inserted in sorted order and the table doesn't have any compressed keys.

String indexes are space compressed. If the first index part is a string, it is also prefix compressed. Space compression makes the index file smaller than the worst-case figure if a string column has a lot of trailing space or is a [VARCHAR](#) column that is not always used to the full length. Prefix compression is used on keys that start with a string. Prefix compression helps if there are many strings with an identical prefix.

In [MyISAM](#) tables, you can also prefix compress numbers by specifying the [PACK_KEYS=1](#) table option when you create the table. Numbers are stored with the high byte first, so this helps when you have many integer keys that have an identical prefix.

13.4.3. [MyISAM](#) Table Storage Formats

[MyISAM](#) supports three different storage formats. Two of them, fixed and dynamic format, are chosen automatically depending on the type of columns you are using. The third, compressed format, can be created only with the [myisampack](#) utility.

When you use [CREATE TABLE](#) or [ALTER TABLE](#) for a table that has no [BLOB](#) or [TEXT](#) columns, you can force the table format to [FIXED](#) or [DYNAMIC](#) with the [ROW_FORMAT](#) table option.

You can decompress tables by specifying [ROW_FORMAT=DEFAULT](#) with [ALTER TABLE](#).

See [Section 12.1.10, “CREATE TABLE Syntax”](#), for information about [ROW_FORMAT](#).

13.4.3.1. Static (Fixed-Length) Table Characteristics

Static format is the default for [MyISAM](#) tables. It is used when the table contains no variable-length columns ([VARCHAR](#), [VARBINARY](#), [BLOB](#), or [TEXT](#)). Each row is stored using a fixed number of bytes.

Of the three [MyISAM](#) storage formats, static format is the simplest and most secure (least subject to corruption). It is also the fastest of the on-disk formats due to the ease with which rows in the data file can be found on disk: To look up a row based on a row number in the index, multiply the row number by the row length to calculate the row position. Also, when scanning a table, it is very easy to read a constant number of rows with each disk read operation.

The security is evidenced if your computer crashes while the MySQL server is writing to a fixed-format [MyISAM](#) file. In this case, [my-isamchk](#) can easily determine where each row starts and ends, so it can usually reclaim all rows except the partially written one. Note that [MyISAM](#) table indexes can always be reconstructed based on the data rows.

Note

Fixed-length row format is only available for tables without [BLOB](#) or [TEXT](#) columns. Creating a table with these columns with an explicit [ROW_FORMAT](#) clause will not raise an error or warning; the format specification will be ignored.

Static-format tables have these characteristics:

- [CHAR](#) and [VARCHAR](#) columns are space-padded to the specified column width, although the column type is not altered. [BINARY](#) and [VARBINARY](#) columns are padded with `0x00` bytes to the column width.
- Very quick.
- Easy to cache.
- Easy to reconstruct after a crash, because rows are located in fixed positions.
- Reorganization is unnecessary unless you delete a huge number of rows and want to return free disk space to the operating system. To do this, use [OPTIMIZE TABLE](#) or [myisamchk -r](#).
- Usually require more disk space than dynamic-format tables.

13.4.3.2. Dynamic Table Characteristics

Dynamic storage format is used if a [MyISAM](#) table contains any variable-length columns ([VARCHAR](#), [VARBINARY](#), [BLOB](#), or [TEXT](#)), or if the table was created with the [ROW_FORMAT=DYNAMIC](#) table option.

Dynamic format is a little more complex than static format because each row has a header that indicates how long it is. A row can become fragmented (stored in non-contiguous pieces) when it is made longer as a result of an update.

You can use [OPTIMIZE TABLE](#) or [myisamchk -r](#) to defragment a table. If you have fixed-length columns that you access or change frequently in a table that also contains some variable-length columns, it might be a good idea to move the variable-length columns to other tables just to avoid fragmentation.

Dynamic-format tables have these characteristics:

- All string columns are dynamic except those with a length less than four.
- Each row is preceded by a bitmap that indicates which columns contain the empty string (for string columns) or zero (for numeric columns). Note that this does not include columns that contain [NULL](#) values. If a string column has a length of zero after trailing space removal, or a numeric column has a value of zero, it is marked in the bitmap and not saved to disk. Non-empty strings are saved as a length byte plus the string contents.
- Much less disk space usually is required than for fixed-length tables.
- Each row uses only as much space as is required. However, if a row becomes larger, it is split into as many pieces as are required, resulting in row fragmentation. For example, if you update a row with information that extends the row length, the row becomes fragmented. In this case, you may have to run [OPTIMIZE TABLE](#) or [myisamchk -r](#) from time to time to improve performance. Use [myisamchk -ei](#) to obtain table statistics.
- More difficult than static-format tables to reconstruct after a crash, because rows may be fragmented into many pieces and links (fragments) may be missing.
- The expected row length for dynamic-sized rows is calculated using the following expression:

```
3
+ (number of columns + 7) / 8
+ (number of char columns)
+ (packed size of numeric columns)
+ (length of strings)
+ (number of NULL columns + 7) / 8
```

There is a penalty of 6 bytes for each link. A dynamic row is linked whenever an update causes an enlargement of the row. Each new link is at least 20 bytes, so the next enlargement probably goes in the same link. If not, another link is created. You can find the number of links using [myisamchk -ed](#). All links may be removed with [OPTIMIZE TABLE](#) or [myisamchk -r](#).

13.4.3.3. Compressed Table Characteristics

Compressed storage format is a read-only format that is generated with the [mysampack](#) tool. Compressed tables can be uncompressed with [myisamchk](#).

Compressed tables have the following characteristics:

- Compressed tables take very little disk space. This minimizes disk usage, which is helpful when using slow disks (such as CD-ROMs).
- Each row is compressed separately, so there is very little access overhead. The header for a row takes up one to three bytes depending on the biggest row in the table. Each column is compressed differently. There is usually a different Huffman tree for each column. Some of the compression types are:
 - Suffix space compression.
 - Prefix space compression.
 - Numbers with a value of zero are stored using one bit.

- If values in an integer column have a small range, the column is stored using the smallest possible type. For example, a **BIGINT** column (eight bytes) can be stored as a **TINYINT** column (one byte) if all its values are in the range from **-128** to **127**.
- If a column has only a small set of possible values, the data type is converted to **ENUM**.
- A column may use any combination of the preceding compression types.
- Can be used for fixed-length or dynamic-length rows.

Note. While a compressed table is read-only, and you cannot therefore update or add rows in the table, DDL (Data Definition Language) operations are still valid. For example, you may still use **DROP** to drop the table, and **TRUNCATE** to empty the table.

13.4.4. MyISAM Table Problems

The file format that MySQL uses to store data has been extensively tested, but there are always circumstances that may cause database tables to become corrupted. The following discussion describes how this can happen and how to handle it.

13.4.4.1. Corrupted MyISAM Tables

Even though the **MyISAM** table format is very reliable (all changes to a table made by an SQL statement are written before the statement returns), you can still get corrupted tables if any of the following events occur:

- The **mysqld** process is killed in the middle of a write.
- An unexpected computer shutdown occurs (for example, the computer is turned off).
- Hardware failures.
- You are using an external program (such as **myisamchk**) to modify a table that is being modified by the server at the same time.
- A software bug in the MySQL or **MyISAM** code.

Typical symptoms of a corrupt table are:

- You get the following error while selecting data from the table:

```
Incorrect key file for table: '...'. Try to repair it
```

- Queries don't find rows in the table or return incomplete results.

You can check the health of a **MyISAM** table using the **CHECK TABLE** statement, and repair a corrupted **MyISAM** table with **REPAIR TABLE**. When **mysqld** is not running, you can also check or repair a table with the **myisamchk** command. See [Section 12.5.2.3, “CHECK TABLE Syntax”](#), [Section 12.5.2.6, “REPAIR TABLE Syntax”](#), and [Section 7.5, “myisamchk — MyISAM Table-Maintenance Utility”](#).

If your tables become corrupted frequently, you should try to determine why this is happening. The most important thing to know is whether the table became corrupted as a result of a server crash. You can verify this easily by looking for a recent **restarted mysqld** message in the error log. If there is such a message, it is likely that table corruption is a result of the server dying. Otherwise, corruption may have occurred during normal operation. This is a bug. You should try to create a reproducible test case that demonstrates the problem. See [Section B.1.4.2, “What to Do If MySQL Keeps Crashing”](#), and [MySQL Internals: Porting](#).

MySQL Enterprise

Find out about problems before they occur. Subscribe to the MySQL Enterprise Monitor for expert advice about the state of your servers. For more information see <http://www.mysql.com/products/enterprise/advisors.html>.

13.4.4.2. Problems from Tables Not Being Closed Properly

Each **MyISAM** index file (**.MYI** file) has a counter in the header that can be used to check whether a table has been closed properly. If you get the following warning from **CHECK TABLE** or **myisamchk**, it means that this counter has gone out of sync:

```
clients are using or haven't closed the table properly
```

This warning doesn't necessarily mean that the table is corrupted, but you should at least check the table.

The counter works as follows:

- The first time a table is updated in MySQL, a counter in the header of the index files is incremented.
- The counter is not changed during further updates.
- When the last instance of a table is closed (because a [FLUSH TABLES](#) operation was performed or because there is no room in the table cache), the counter is decremented if the table has been updated at any point.
- When you repair the table or check the table and it is found to be okay, the counter is reset to zero.
- To avoid problems with interaction with other processes that might check the table, the counter is not decremented on close if it was zero.

In other words, the counter can become incorrect only under these conditions:

- A [MyISAM](#) table is copied without first issuing [LOCK TABLES](#) and [FLUSH TABLES](#).
- MySQL has crashed between an update and the final close. (Note that the table may still be okay, because MySQL always issues writes for everything between each statement.)
- A table was modified by [myisamchk --recover](#) or [myisamchk --update-state](#) at the same time that it was in use by [mysqld](#).
- Multiple [mysqld](#) servers are using the table and one server performed a [REPAIR TABLE](#) or [CHECK TABLE](#) on the table while it was in use by another server. In this setup, it is safe to use [CHECK TABLE](#), although you might get the warning from other servers. However, [REPAIR TABLE](#) should be avoided because when one server replaces the data file with a new one, this is not known to the other servers.

In general, it is a bad idea to share a data directory among multiple servers. See [Section 5.12, “Running Multiple MySQL Servers on the Same Machine”](#), for additional discussion.

13.5. The [InnoDB](#) Storage Engine

13.5.1. [InnoDB](#) Overview

[InnoDB](#) provides MySQL with a transaction-safe ([ACID](#) compliant) storage engine that has commit, rollback, and crash recovery capabilities. [InnoDB](#) does locking on the row level and also provides an Oracle-style consistent non-locking read in [SELECT](#) statements. These features increase multi-user concurrency and performance. There is no need for lock escalation in [InnoDB](#) because row-level locks fit in very little space. [InnoDB](#) also supports [FOREIGN KEY](#) constraints. You can freely mix [InnoDB](#) tables with tables from other MySQL storage engines, even within the same statement.

[InnoDB](#) has been designed for maximum performance when processing large data volumes. Its CPU efficiency is probably not matched by any other disk-based relational database engine.

Fully integrated with MySQL Server, the [InnoDB](#) storage engine maintains its own buffer pool for caching data and indexes in main memory. [InnoDB](#) stores its tables and indexes in a tablespace, which may consist of several files (or raw disk partitions). This is different from, for example, [MyISAM](#) tables where each table is stored using separate files. [InnoDB](#) tables can be of any size even on operating systems where file size is limited to 2GB.

[InnoDB](#) is included in binary distributions by default. The Windows Essentials installer makes [InnoDB](#) the MySQL default storage engine on Windows.

[InnoDB](#) is used in production at numerous large database sites requiring high performance. The famous Internet news site Slashdot.org runs on [InnoDB](#). Mytrix, Inc. stores over 1TB of data in [InnoDB](#), and another site handles an average load of 800 inserts/updates per second in [InnoDB](#).

InnoDB is published under the same GNU GPL License Version 2 (of June 1991) as MySQL. For more information on MySQL licensing, see <http://www.mysql.com/company/legal/licensing/>.

Additional resources

- A forum dedicated to the **InnoDB** storage engine is available at <http://forums.mysql.com/list.php?22>.

13.5.2. InnoDB Contact Information

Contact information for Innobase Oy, producer of the **InnoDB** engine:

```
Web site: http://www.innodb.com/
Email: <sales@innodb.com>
Phone: +358-9-6969 3250 (office)
      +358-40-5617367 (mobile)

Innbase Oy Inc.
World Trade Center Helsinki
Aleksanterinkatu 17
P.O.Box 800
00101 Helsinki
Finland
```

13.5.3. InnoDB Configuration

The **InnoDB** storage engine is enabled by default. If you don't want to use **InnoDB** tables, you can add the `skip-innodb` option to your MySQL option file.

Note

InnoDB provides MySQL with a transaction-safe (**ACID** compliant) storage engine that has commit, rollback, and crash recovery capabilities. **However, it cannot do so** if the underlying operating system or hardware does not work as advertised. Many operating systems or disk subsystems may delay or reorder write operations to improve performance. On some operating systems, the very system call that should wait until all unwritten data for a file has been flushed — `fsync()` — might actually return before the data has been flushed to stable storage. Because of this, an operating system crash or a power outage may destroy recently committed data, or in the worst case, even corrupt the database because of write operations having been reordered. If data integrity is important to you, you should perform some “pull-the-plug” tests before using anything in production. On Mac OS X 10.3 and up, **InnoDB** uses a special `fcntl()` file flush method. Under Linux, it is advisable to **disable the write-back cache**.

On ATAPI hard disks, a command such `hdparm -W0 /dev/hda` may work to disable the write-back cache. **Beware that some drives or disk controllers may be unable to disable the write-back cache.**

Two important disk-based resources managed by the **InnoDB** storage engine are its tablespace data files and its log files.

Note

If you specify no **InnoDB** configuration options, MySQL creates an auto-extending 10MB data file named `ibdata1` and two 5MB log files named `ib_logfile0` and `ib_logfile1` in the MySQL data directory. To get good performance, you should explicitly provide **InnoDB** parameters as discussed in the following examples. Naturally, you should edit the settings to suit your hardware and requirements.

Note

It is not a good idea to configure **InnoDB** to use datafiles or logfiles on NFS volumes. Otherwise, the files might be locked by other processes and become unavailable for use by MySQL.

MySQL Enterprise

For advice on settings suitable to your specific circumstances, subscribe to the MySQL Enterprise Monitor. For more information see <http://www.mysql.com/products/enterprise/advisors.html>.

The examples shown here are representative. See [Section 13.5.4, “InnoDB Startup Options and System Variables”](#) for additional information about **InnoDB**-related configuration parameters.

To set up the **InnoDB** tablespace files, use the `innodb_data_file_path` option in the `[mysqld]` section of the `my.cnf` option file. On Windows, you can use `my.ini` instead. The value of `innodb_data_file_path` should be a list of one or more data file specifications. If you name more than one data file, separate them by semicolon (‘;’) characters:

```
innodb_data_file_path=datafile_spec1[;datafile_spec2]...
```

For example, a setting that explicitly creates a tablespace having the same characteristics as the default is as follows:

```
[mysqld]
innodb_data_file_path=ibdata1:10M:autoextend
```

This setting configures a single 10MB data file named `ibdata1` that is auto-extending. No location for the file is given, so by default, **InnoDB** creates it in the MySQL data directory.

Sizes are specified using **M** or **G** suffix letters to indicate units of MB or GB.

A tablespace containing a fixed-size 50MB data file named `ibdata1` and a 50MB auto-extending file named `ibdata2` in the data directory can be configured like this:

```
[mysqld]
innodb_data_file_path=ibdata1:50M;ibdata2:50M:autoextend
```

The full syntax for a data file specification includes the filename, its size, and several optional attributes:

```
file_name:file_size[:autoextend[:max:max_file_size]]
```

The `autoextend` attribute and those following can be used only for the last data file in the `innodb_data_file_path` line.

If you specify the `autoextend` option for the last data file, **InnoDB** extends the data file if it runs out of free space in the tablespace. The increment is 8MB at a time by default. It can be modified by changing the `innodb_autoextend_increment` system variable.

If the disk becomes full, you might want to add another data file on another disk. Instructions for reconfiguring an existing tablespace are given in [Section 13.5.7, “Adding and Removing InnoDB Data and Log Files”](#).

InnoDB is not aware of the filesystem maximum file size, so be cautious on filesystems where the maximum file size is a small value such as 2GB. To specify a maximum size for an auto-extending data file, use the `max` attribute. The following configuration allows `ibdata1` to grow up to a limit of 500MB:

```
[mysqld]
innodb_data_file_path=ibdata1:10M:autoextend:max:500M
```

InnoDB creates tablespace files in the MySQL data directory by default. To specify a location explicitly, use the `innodb_data_home_dir` option. For example, to use two files named `ibdata1` and `ibdata2` but create them in the `/ibdata` directory, configure **InnoDB** like this:

```
[mysqld]
innodb_data_home_dir = /ibdata
innodb_data_file_path=ibdata1:50M;ibdata2:50M:autoextend
```

Note

InnoDB does not create directories, so make sure that the `/ibdata` directory exists before you start the server. This is also true of any log file directories that you configure. Use the Unix or DOS `mkdir` command to create any necessary directories.

InnoDB forms the directory path for each data file by textually concatenating the value of `innodb_data_home_dir` to the data file name, adding a pathname separator (slash or backslash) between values if necessary. If the `innodb_data_home_dir` option is not mentioned in `my.cnf` at all, the default value is the “dot” directory `./`, which means the MySQL data directory. (The MySQL server changes its current working directory to its data directory when it begins executing.)

If you specify `innodb_data_home_dir` as an empty string, you can specify absolute paths for the data files listed in the `innodb_data_file_path` value. The following example is equivalent to the preceding one:

```
[mysqld]
innodb_data_home_dir =
```

```
innodb_data_file_path=/ibdata/ibdata1:50M;/ibdata/ibdata2:50M:autoextend
```

A simple `my.cnf` example. Suppose that you have a computer with 128MB RAM and one hard disk. The following example shows possible configuration parameters in `my.cnf` or `my.ini` for InnoDB, including the `autoextend` attribute. The example suits most users, both on Unix and Windows, who do not want to distribute InnoDB data files and log files onto several disks. It creates an auto-extending data file `ibdata1` and two InnoDB log files `ib_logfile0` and `ib_logfile1` in the MySQL data directory.

```
[mysqld]
# You can write your other MySQL server options here
# ...
# Data files must be able to hold your data and indexes.
# Make sure that you have enough free disk space.
innodb_data_file_path = ibdata1:10M:autoextend
#
# Set buffer pool size to 50-80% of your computer's memory
innodb_buffer_pool_size=70M
innodb_additional_mem_pool_size=10M
#
# Set the log file size to about 25% of the buffer pool size
innodb_log_file_size=20M
innodb_log_buffer_size=8M
#
innodb_flush_log_at_trx_commit=1
```

Make sure that the MySQL server has the proper access rights to create files in the data directory. More generally, the server must have access rights in any directory where it needs to create data files or log files.

Note that data files must be less than 2GB in some filesystems. The combined size of the log files must be less than 4GB. The combined size of data files must be at least 10MB.

When you create an InnoDB tablespace for the first time, it is best that you start the MySQL server from the command prompt. InnoDB then prints the information about the database creation to the screen, so you can see what is happening. For example, on Windows, if `mysqld` is located in `C:\Program Files\MySQL\MySQL Server 5.1\bin`, you can start it like this:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.1\bin\mysqld" --console
```

If you do not send server output to the screen, check the server's error log to see what InnoDB prints during the startup process.

See [Section 13.5.5, “Creating the InnoDB Tablespace”](#), for an example of what the information displayed by InnoDB should look like.

You can place InnoDB options in the `[mysqld]` group of any option file that your server reads when it starts. The locations for option files are described in [Section 4.3.2, “Using Option Files”](#).

If you installed MySQL on Windows using the installation and configuration wizards, the option file will be the `my.ini` file located in your MySQL installation directory. See [Section 2.3.4.14, “The Location of the my.ini File”](#).

If your PC uses a boot loader where the `C:` drive is not the boot drive, your only option is to use the `my.ini` file in your Windows directory (typically `C:\WINDOWS`). You can use the `SET` command at the command prompt in a console window to print the value of `WINDIR`:

```
C:\> SET WINDIR
windir=C:\WINDOWS
```

If you want to make sure that `mysqld` reads options only from a specific file, you can use the `--defaults-file` option as the first option on the command line when starting the server:

```
mysqld --defaults-file=your_path_to_my.cnf
```

An advanced `my.cnf` example. Suppose that you have a Linux computer with 2GB RAM and three 60GB hard disks at directory paths `/`, `/dr2` and `/dr3`. The following example shows possible configuration parameters in `my.cnf` for InnoDB.

```
[mysqld]
# You can write your other MySQL server options here
# ...
innodb_data_home_dir =
#
# Data files must be able to hold your data and indexes
innodb_data_file_path = /db/ibdata1:2000M;/dr2/db/ibdata2:2000M:autoextend
#
```

```
# Set buffer pool size to 50-80% of your computer's memory,
# but make sure on Linux x86 total memory usage is < 2GB
innodb_buffer_pool_size=1G
innodb_additional_mem_pool_size=20M
innodb_log_group_home_dir = /dr3/iblogs
#
innodb_log_files_in_group = 2
#
# Set the log file size to about 25% of the buffer pool size
innodb_log_file_size=250M
innodb_log_buffer_size=8M
#
innodb_flush_log_at_trx_commit=1
innodb_lock_wait_timeout=50
#
# Uncomment the next lines if you want to use them
#innodb_thread_concurrency=5
```

In some cases, database performance improves if all the data is not placed on the same physical disk. Putting log files on a different disk from data is very often beneficial for performance. The example illustrates how to do this. It places the two data files on different disks and places the log files on the third disk. **InnoDB** fills the tablespace beginning with the first data file. You can also use raw disk partitions (raw devices) as **InnoDB** data files, which may speed up I/O. See [Section 13.5.3.2, “Using Raw Devices for the Shared Tablespace”](#).

Warning

On 32-bit GNU/Linux x86, you must be careful not to set memory usage too high. **glibc** may allow the process heap to grow over thread stacks, which crashes your server. It is a risk if the value of the following expression is close to or exceeds 2GB:

```
innodb_buffer_pool_size
+ key_buffer_size
+ max_connections*(sort_buffer_size+read_buffer_size+binlog_cache_size)
+ max_connections*2MB
```

Each thread uses a stack (often 2MB, but only 256KB in MySQL AB binaries) and in the worst case also uses `sort_buffer_size` + `read_buffer_size` additional memory.

By compiling MySQL yourself, you can use up to 64GB of physical memory in 32-bit Windows. See the description for `innodb_buffer_pool_awesome_mem_mb` in [Section 13.5.4, “InnoDB Startup Options and System Variables”](#).

How to tune other `mysqld` server parameters? The following values are typical and suit most users:

```
[mysqld]
skip-external-locking
max_connections=200
read_buffer_size=1M
sort_buffer_size=1M
#
# Set key_buffer to 5 - 50% of your RAM depending on how much
# you use MyISAM tables, but keep key_buffer_size + InnoDB
# buffer pool size < 80% of your RAM
key_buffer_size=va lue
```

13.5.3.1. Using Per-Table Tablespaces

You can store each **InnoDB** table and its indexes in its own file. This feature is called “multiple tablespaces” because in effect each table has its own tablespace.

Using multiple tablespaces can be beneficial to users who want to move specific tables to separate physical disks or who wish to restore backups of single tables quickly without interrupting the use of the remaining **InnoDB** tables.

You can enable multiple tablespaces by adding this line to the `[mysqld]` section of `my.cnf`:

```
[mysqld]
innodb_file_per_table
```

After restarting the server, **InnoDB** stores each newly created table into its own file `tbl_name.ibd` in the database directory where the table belongs. This is similar to what the **MyISAM** storage engine does, but **MyISAM** divides the table into a data file `tbl_name.MYD` and the index file `tbl_name.MYI`. For **InnoDB**, the data and the indexes are stored together in the `.ibd` file. The `tbl_name.frm` file is still created as usual.

If you remove the `innodb_file_per_table` line from `my.cnf` and restart the server, **InnoDB** creates tables inside the shared tablespace files again.

`innodb_file_per_table` affects only table creation, not access to existing tables. If you start the server with this option, new tables are created using `.ibd` files, but you can still access tables that exist in the shared tablespace. If you remove the option and restart the server, new tables are created in the shared tablespace, but you can still access any tables that were created using multiple tablespaces.

Note

InnoDB always needs the shared tablespace because it puts its internal data dictionary and undo logs there. The `.ibd` files are not sufficient for **InnoDB** to operate.

Note

You cannot freely move `.ibd` files between database directories as you can with **MyISAM** table files. This is because the table definition that is stored in the **InnoDB** shared tablespace includes the database name, and because **InnoDB** must preserve the consistency of transaction IDs and log sequence numbers.

To move an `.ibd` file and the associated table from one database to another, use a `RENAME TABLE` statement:

```
RENAME TABLE db1.tbl_name TO db2.tbl_name;
```

If you have a “clean” backup of an `.ibd` file, you can restore it to the MySQL installation from which it originated as follows:

1. Issue this `ALTER TABLE` statement:

```
ALTER TABLE tbl_name DISCARD TABLESPACE;
```

Caution

This statement deletes the current `.ibd` file.

2. Put the backup `.ibd` file back in the proper database directory.
3. Issue this `ALTER TABLE` statement:

```
ALTER TABLE tbl_name IMPORT TABLESPACE;
```

In this context, a “clean” `.ibd` file backup means:

- There are no uncommitted modifications by transactions in the `.ibd` file.
- There are no unmerged insert buffer entries in the `.ibd` file.
- Purge has removed all delete-marked index records from the `.ibd` file.
- `mysqld` has flushed all modified pages of the `.ibd` file from the buffer pool to the file.

You can make a clean backup `.ibd` file using the following method:

1. Stop all activity from the `mysqld` server and commit all transactions.
2. Wait until `SHOW ENGINE INNODB STATUS` shows that there are no active transactions in the database, and the main thread status of **InnoDB** is `Waiting for server activity`. Then you can make a copy of the `.ibd` file.

Another method for making a clean copy of an `.ibd` file is to use the commercial **InnoDB Hot Backup** tool:

1. Use **InnoDB Hot Backup** to back up the **InnoDB** installation.
2. Start a second **mysqld** server on the backup and let it clean up the **.ibd** files in the backup.

13.5.3.2. Using Raw Devices for the Shared Tablespace

You can use raw disk partitions as data files in the shared tablespace. By using a raw disk, you can perform non-buffered I/O on Windows and on some Unix systems without filesystem overhead, which may improve performance.

When you create a new data file, you must put the keyword **newraw** immediately after the data file size in **innodb_data_file_path**. The partition must be at least as large as the size that you specify. Note that 1MB in **InnoDB** is 1024×1024 bytes, whereas 1MB in disk specifications usually means 1,000,000 bytes.

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=/dev/hdd1:3Gnewraw;/dev/hdd2:2Gnewraw
```

The next time you start the server, **InnoDB** notices the **newraw** keyword and initializes the new partition. However, do not create or change any **InnoDB** tables yet. Otherwise, when you next restart the server, **InnoDB** reinitializes the partition and your changes are lost. (As a safety measure **InnoDB** prevents users from modifying data when any partition with **newraw** is specified.)

After **InnoDB** has initialized the new partition, stop the server, change **newraw** in the data file specification to **raw**:

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=/dev/hdd1:5Graw;/dev/hdd2:2Graw
```

Then restart the server and **InnoDB** allows changes to be made.

On Windows, you can allocate a disk partition as a data file like this:

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=\\.\D: :10Gnewraw
```

The **\\.** corresponds to the Windows syntax of **\\.** for accessing physical drives.

When you use raw disk partitions, be sure that they have permissions that allow read and write access by the account used for running the MySQL server.

13.5.4. InnoDB Startup Options and System Variables

This section describes the **InnoDB**-related command options and system variables. System variables that are true or false can be enabled at server startup by naming them, or disabled by using a **skip-** prefix. For example, to enable or disable **InnoDB** checksums, you can use **--innodb_checksums** or **--skip-innodb_checksums** on the command line, or **innodb_checksums** or **skip-innodb_checksums** in an option file. System variables that take a numeric value can be specified as **--var_name=value** on the command line or as **var_name=value** in option files. For more information on specifying options and system variables, see [Section 4.3, “Specifying Program Options”](#). Many of the system variables can be changed at runtime (see [Section 5.2.4.2, “Dynamic System Variables”](#)).

MySQL Enterprise

The MySQL Enterprise Monitor provides expert advice on **InnoDB** start-up options and related system variables. For more information see <http://www.mysql.com/products/enterprise/advisors.html>.

InnoDB command options:

- **--innodb**
Enables the **InnoDB** storage engine, if the server was compiled with **InnoDB** support. Use **--skip-innodb** to disable **InnoDB**.
- **--innodb_status_file**
Causes **InnoDB** to create a file named **<datadir>/innodb_status.<pid>** in the MySQL data directory. **InnoDB** periodic-

ally writes the output of `SHOW ENGINE INNODB STATUS` to this file.

InnoDB system variables:

- `innodb_additional_mem_pool_size`

The size in bytes of a memory pool InnoDB uses to store data dictionary information and other internal data structures. The more tables you have in your application, the more memory you need to allocate here. If InnoDB runs out of memory in this pool, it starts to allocate memory from the operating system and writes warning messages to the MySQL error log. The default value is 1MB.

- `innodb_autoextend_increment`

The increment size (in MB) for extending the size of an auto-extending tablespace when it becomes full. The default value is 8.

- `innodb_buffer_pool_ave_mem_mb`

The size of the buffer pool (in MB), if it is placed in the AWE memory. This is relevant only in 32-bit Windows. If your 32-bit Windows operating system supports more than 4GB memory, using so-called “Address Windowing Extensions,” you can allocate the InnoDB buffer pool into the AWE physical memory using this variable. The maximum possible value for this variable is 63000. If it is greater than 0, `innodb_buffer_pool_size` is the window in the 32-bit address space of `mysqld` where InnoDB maps that AWE memory. A good value for `innodb_buffer_pool_size` is 500MB.

To take advantage of AWE memory, you will need to recompile MySQL yourself. The current project settings needed for doing this can be found in the `storage/innobase/os/os0proj.c` source file.

- `innodb_autoinc_lock_mode`

The locking mode to use for generating auto-increment values. The allowable values are 0, 1, or 2, for “traditional”, “consecutive”, or “interleaved” lock mode, respectively. The characteristics of these modes are described in [Section 13.5.6.3, “How AUTO_INCREMENT Handling Works in InnoDB”](#).

This variable was added in MySQL 5.1.22 with a default of 1 (“consecutive” lock mode). Before 5.1.22, InnoDB uses “traditional” lock mode.

- `innodb_buffer_pool_size`

The size in bytes of the memory buffer InnoDB uses to cache data and indexes of its tables. The larger you set this value, the less disk I/O is needed to access data in tables. On a dedicated database server, you may set this to up to 80% of the machine physical memory size. However, do not set it too large because competition for physical memory might cause paging in the operating system.

- `innodb_checksums`

InnoDB can use checksum validation on all pages read from the disk to ensure extra fault tolerance against broken hardware or data files. This validation is enabled by default. However, under some rare circumstances (such as when running benchmarks) this extra safety feature is unneeded and can be disabled with `--skip-innodb-checksums`.

- `innodb_commit_concurrency`

The number of threads that can commit at the same time. Setting this parameter to 0 allows any number of transactions to commit simultaneously.

- `innodb_concurrency_tickets`

The number of threads that can enter InnoDB concurrently is determined by the `innodb_thread_concurrency` variable. A thread is placed in a queue when it tries to enter InnoDB if the number of threads has already reached the concurrency limit. When a thread is allowed to enter InnoDB, it is given a number of “free tickets” equal to the value of `innodb_concurrency_tickets`, and the thread can enter and leave InnoDB freely until it has used up its tickets. After that point, the thread again becomes subject to the concurrency check (and possible queuing) the next time it tries to enter InnoDB.

- `innodb_data_file_path`

The paths to individual data files and their sizes. The full directory path to each data file is formed by concatenating `innodb_data_home_dir` to each path specified here. The file sizes are specified in MB or GB (1024MB) by appending `M` or `G` to

the size value. The sum of the sizes of the files must be at least 10MB. If you do not specify `innodb_data_file_path`, the default behavior is to create a single 10MB auto-extending data file named `ibdata1`. The size limit of individual files is determined by your operating system. You can set the file size to more than 4GB on those operating systems that support big files. You can also use raw disk partitions as data files. See [Section 13.5.3.2, “Using Raw Devices for the Shared Tablespace”](#).

- `innodb_data_home_dir`

The common part of the directory path for all **InnoDB** data files. If you do not set this value, the default is the MySQL data directory. You can specify the value as an empty string, in which case you can use absolute file paths in `innodb_data_file_path`.

- `innodb_doublewrite`

By default, **InnoDB** stores all data twice, first to the doublewrite buffer, and then to the actual data files. This variable is enabled by default. It can be turned off with `--skip-innodb_doublewrite` for benchmarks or cases when top performance is needed rather than concern for data integrity or possible failures.

- `innodb_fast_shutdown`

If you set this variable to 0, **InnoDB** does a full purge and an insert buffer merge before a shutdown. These operations can take minutes, or even hours in extreme cases. If you set this variable to 1, **InnoDB** skips these operations at shutdown. The default value is 1. If you set it to 2, **InnoDB** will just flush its logs and then shut down cold, as if MySQL had crashed; no committed transaction will be lost, but crash recovery will be done at the next startup. A value of 2 cannot be used on NetWare.

- `innodb_file_io_threads`

The number of file I/O threads in **InnoDB**. Normally, this should be left at the default value of 4, but disk I/O on Windows may benefit from a larger number. On Unix, increasing the number has no effect; **InnoDB** always uses the default value.

- `innodb_file_per_table`

If this variable is enabled, **InnoDB** creates each new table using its own `.ibd` file for storing data and indexes, rather than in the shared tablespace. The default is to create tables in the shared tablespace. See [Section 13.5.3.1, “Using Per-Table Tablespaces”](#).

- `innodb_flush_log_at_trx_commit`

When `innodb_flush_log_at_trx_commit` is set to 0, the log buffer is written out to the log file once per second and the flush to disk operation is performed on the log file, but nothing is done at a transaction commit. When this value is 1 (the default), the log buffer is written out to the log file at each transaction commit and the flush to disk operation is performed on the log file. When set to 2, the log buffer is written out to the file at each commit, but the flush to disk operation is not performed on it. However, the flushing on the log file takes place once per second also when the value is 2. Note that the once-per-second flushing is not 100% guaranteed to happen every second, due to process scheduling issues.

The default value of this variable is 1, which is the value that is required for ACID compliance. You can achieve better performance by setting the value different from 1, but then you can lose at most one second worth of transactions in a crash. If you set the value to 0, then any `mysqld` process crash can erase the last second of transactions. If you set the value to 2, then only an operating system crash or a power outage can erase the last second of transactions. However, **InnoDB**'s crash recovery is not affected and thus crash recovery does work regardless of the value. Note that many operating systems and some disk hardware fool the flush-to-disk operation. They may tell `mysqld` that the flush has taken place, even though it has not. Then the durability of transactions is not guaranteed even with the setting 1, and in the worst case a power outage can even corrupt the **InnoDB** database. Using a battery-backed disk cache in the SCSI disk controller or in the disk itself speeds up file flushes, and makes the operation safer. You can also try using the Unix command `hdparm` to disable the caching of disk writes in hardware caches, or use some other command specific to the hardware vendor.

Note: For the greatest possible durability and consistency in a replication setup using **InnoDB** with transactions, you should use `innodb_flush_log_at_trx_commit=1` and `sync_binlog=1` in your master server `my.cnf` file.

- `innodb_flush_method`

If set to `fdatasync` (the default), **InnoDB** uses `fsync()` to flush both the data and log files. If set to `O_DSYNC`, **InnoDB** uses `O_SYNC` to open and flush the log files, but uses `fsync()` to flush the data files. If `O_DIRECT` is specified (available on some GNU/Linux versions, FreeBSD and Solaris), **InnoDB** uses `O_DIRECT` (or `directio()` on Solaris) to open the data files, and uses `fsync()` to flush both the data and log files. Note that **InnoDB** uses `fsync()` instead of `fdatasync()`, and it does not use `O_DSYNC` by default because there have been problems with it on many varieties of Unix. This variable is relevant only for Unix. On Windows, the flush method is always `async_unbuffered` and cannot be changed.

Different values of this variable can have a marked effect on **InnoDB performance**. For example, on some systems where **In-**

`noDB` data and log files are located on a SAN, it has been found that setting `innodb_flush_method` to `O_DIRECT` can degrade performance of simple `SELECT` statements by a factor of three.

- `innodb_force_recovery`

The crash recovery mode. Warning: This variable should be set greater than 0 only in an emergency situation when you want to dump your tables from a corrupt database! Possible values are from 1 to 6. The meanings of these values are described in [Section 13.5.8.1, “Forcing InnoDB Recovery”](#). As a safety measure, `InnoDB` prevents any changes to its data when this variable is greater than 0.

- `innodb_lock_wait_timeout`

The timeout in seconds an `InnoDB` transaction may wait for a lock before being rolled back. `InnoDB` automatically detects transaction deadlocks in its own lock table and rolls back the transaction. `InnoDB` notices locks set using the `LOCK TABLES` statement. The default is 50 seconds.

- `innodb_locks_unsafe_for_binlog`

This variable controls next-key locking in `InnoDB` searches and index scans. By default, this variable is 0 (disabled), which means that next-key locking is enabled.

Normally, `InnoDB` uses an algorithm called *next-key locking*. `InnoDB` performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on any index records it encounters. Thus, the row-level locks are actually index record locks. The locks that `InnoDB` sets on index records also affect the “gap” preceding that index record. If a user has a shared or exclusive lock on record *R* in an index, another user cannot insert a new index record immediately before *R* in the order of the index. Enabling this variable causes `InnoDB` not to use next-key locking in searches or index scans. Next-key locking is still used to ensure foreign key constraints and duplicate key checking. Note that enabling this variable may cause phantom problems: Suppose that you want to read and lock all children from the `child` table with an identifier value larger than 100, with the intention of updating some column in the selected rows later:

```
SELECT * FROM child WHERE id > 100 FOR UPDATE;
```

Suppose that there is an index on the `id` column. The query scans that index starting from the first record where `id` is greater than 100. If the locks set on the index records do not lock out inserts made in the gaps, another client can insert a new row into the table. If you execute the same `SELECT` within the same transaction, you see a new row in the result set returned by the query. This also means that if new items are added to the database, `InnoDB` does not guarantee serializability. Therefore, if this variable is enabled, `InnoDB` guarantees at most isolation level `READ COMMITTED`. (Conflict serializability is still guaranteed.)

Enabling this variable has an additional effect: `InnoDB` in an `UPDATE` or a `DELETE` only locks rows that it updates or deletes. This greatly reduces the probability of deadlocks, but they can happen. Note that enabling this variable still does not allow operations such as `UPDATE` to overtake other similar operations (such as another `UPDATE`) even in the case when they affect different rows. Consider the following example, beginning with this table:

```
CREATE TABLE A(A INT NOT NULL, B INT) ENGINE = InnoDB;
INSERT INTO A VALUES (1,2), (2,3), (3,2), (4,3), (5,2);
COMMIT;
```

Suppose that one client executes these statements:

```
SET AUTOCOMMIT = 0;
UPDATE A SET B = 5 WHERE B = 3;
```

Then suppose that another client executes these statements following those of the first client:

```
SET AUTOCOMMIT = 0;
UPDATE A SET B = 4 WHERE B = 2;
```

In this case, the second `UPDATE` must wait for a commit or rollback of the first `UPDATE`. The first `UPDATE` has an exclusive lock on row (2,3), and the second `UPDATE` while scanning rows also tries to acquire an exclusive lock for the same row, which it cannot have. This is because `UPDATE` first acquires an exclusive lock on a row and then determines whether the row belongs to the result set. If not, it releases the unnecessary lock, when the `innodb_locks_unsafe_for_binlog` variable is enabled.

Therefore, `InnoDB` executes `UPDATE` one as follows:

```
x-lock(1,2)
unlock(1,2)
```

```
x-lock(2,3)
update(2,3) to (2,5)
x-lock(3,2)
unlock(3,2)
x-lock(4,3)
update(4,3) to (4,5)
x-lock(5,2)
unlock(5,2)
```

InnoDB executes **UPDATE** two as follows:

```
x-lock(1,2)
update(1,2) to (1,4)
x-lock(2,3) - wait for query one to commit or rollback
```

- **innodb_log_archive**

Whether to log InnoDB archive files. This variable is present for historical reasons, but is unused. Recovery from a backup is done by MySQL using its own log files, so there is no need to archive InnoDB log files. The default for this variable is 0.

- **innodb_log_buffer_size**

The size in bytes of the buffer that InnoDB uses to write to the log files on disk. Sensible values range from 1MB to 8MB. The default is 1MB. A large log buffer allows large transactions to run without a need to write the log to disk before the transactions commit. Thus, if you have big transactions, making the log buffer larger saves disk I/O.

- **innodb_log_file_size**

The size in bytes of each log file in a log group. The combined size of log files must be less than 4GB on 32-bit computers. The default is 5MB. Sensible values range from 1MB to $1/N$ -th of the size of the buffer pool, where N is the number of log files in the group. The larger the value, the less checkpoint flush activity is needed in the buffer pool, saving disk I/O. But larger log files also mean that recovery is slower in case of a crash.

- **innodb_log_files_in_group**

The number of log files in the log group. InnoDB writes to the files in a circular fashion. The default (and recommended) is 2.

- **innodb_log_group_home_dir**

The directory path to the InnoDB log files. If you do not specify any InnoDB log variables, the default is to create two 5MB files names `ib_logfile0` and `ib_logfile1` in the MySQL data directory.

- **innodb_max_dirty_pages_pct**

This is an integer in the range from 0 to 100. The default is 90. The main thread in InnoDB tries to write pages from the buffer pool so that the percentage of dirty (not yet written) pages will not exceed this value.

- **innodb_max_purge_lag**

This variable controls how to delay **INSERT**, **UPDATE** and **DELETE** operations when the purge operations are lagging (see [Section 13.5.12, “Implementation of Multi-Versioning”](#)). The default value of this variable is 0, meaning that there are no delays.

The InnoDB transaction system maintains a list of transactions that have delete-marked index records by **UPDATE** or **DELETE** operations. Let the length of this list be *purge_lag*. When *purge_lag* exceeds *innodb_max_purge_lag*, each **INSERT**, **UPDATE** and **DELETE** operation is delayed by $((\text{purge\_lag}/\text{innodb\_max\_purge\_lag}) \times 10) - 5$ milliseconds. The delay is computed in the beginning of a purge batch, every ten seconds. The operations are not delayed if purge cannot run because of an old consistent read view that could see the rows to be purged.

A typical setting for a problematic workload might be 1 million, assuming that our transactions are small, only 100 bytes in size, and we can allow 100MB of unpurged rows in our tables.

- **innodb_mirrored_log_groups**

The number of identical copies of log groups to keep for the database. Currently, this should be set to 1.

- **innodb_open_files**

This variable is relevant only if you use multiple tablespaces in **InnoDB**. It specifies the maximum number of **.ibd** files that **InnoDB** can keep open at one time. The minimum value is 10. The default is 300.

The file descriptors used for **.ibd** files are for **InnoDB** only. They are independent of those specified by the **-open-files-limit** server option, and do not affect the operation of the table cache.

- **innodb_rollback_on_timeout**

In MySQL 5.1, **InnoDB** rolls back only the last statement on a transaction timeout. If this option is given, a transaction timeout causes **InnoDB** to abort and roll back the entire transaction (the same behavior as in MySQL 4.1). This variable was added in MySQL 5.1.15.

- **innodb_stats_on_metadata**

When this variable is enabled (which is the default, as before the variable was created), **InnoDB** updates statistics during metadata statements such as **SHOW TABLE STATUS** or **SHOW INDEX**, or when accessing the **INFORMATION_SCHEMA** tables **TABLES** or **STATISTICS**. (These updates are similar to what happens for **ANALYZE TABLE**.) When disabled, **InnoDB** does not update statistics during these operations. Disabling this variable can improve access speed for schemas that have a large number of tables or indexes. It can also improve the stability of execution plans for queries that involve **InnoDB** tables.

This variable was added in MySQL 5.1.17.

- **innodb_support_xa**

When set to **ON** or 1 (the default), this variable enables **InnoDB** support for two-phase commit in XA transactions. Enabling **innodb_support_xa** causes an extra disk flush for transaction preparation.

If you don't care about using XA, you can disable this variable by setting it to **OFF** or 0 to reduce the number of disk flushes and get better **InnoDB** performance. If you are using replication and/or the binary log then you should set this variable to **ON** or 1 to ensure that the binary log does not get out of sync compared to the table data.

- **innodb_sync_spin_loops**

The number of times a thread waits for an **InnoDB** mutex to be freed before the thread is suspended.

- **innodb_table_locks**

If **AUTOCOMMIT=0**, **InnoDB** honors **LOCK TABLES**; MySQL does not return from **LOCK TABLE ... WRITE** until all other threads have released all their locks to the table. The default value of **innodb_table_locks** is 1, which means that **LOCK TABLES** causes **InnoDB** to lock a table internally if **AUTOCOMMIT=0**.

- **innodb_thread_concurrency**

InnoDB tries to keep the number of operating system threads concurrently inside **InnoDB** less than or equal to the limit given by this variable. Once the number of threads reaches this limit, additional threads are placed into a wait state within a FIFO queue for execution. Threads waiting for locks are not counted in the number of concurrently executing threads.

The correct value for this variable is dependent on environment and workload. You will need to try a range of different values to determine what value works for your application.

The range of this variable is 0 to 1000. You can disable thread concurrency checking by setting the value to 0, which allows **InnoDB** to create as many threads as it needs.

The default value is 20 before MySQL 5.1.11, and 8 from 5.1.11 on.

- **innodb_thread_sleep_delay**

How long **InnoDB** threads sleep before joining the **InnoDB** queue, in microseconds. The default value is 10,000. A value of 0 disables sleep.

- **sync_binlog**

If the value of this variable is positive, the MySQL server synchronizes its binary log to disk (**fdatasync()**) after every **sync_binlog** writes to this binary log. Note that there is one write to the binary log per statement if in autocommit mode, and otherwise one write per transaction. The default value is 0 which does no synchronizing to disk. A value of 1 is the safest choice, be-

cause in the event of a crash you lose at most one statement/transaction from the binary log; however, it is also the slowest choice (unless the disk has a battery-backed cache, which makes synchronization very fast).

13.5.5. Creating the InnoDB Tablespace

Suppose that you have installed MySQL and have edited your option file so that it contains the necessary InnoDB configuration parameters. Before starting MySQL, you should verify that the directories you have specified for InnoDB data files and log files exist and that the MySQL server has access rights to those directories. InnoDB does not create directories, only files. Check also that you have enough disk space for the data and log files.

It is best to run the MySQL server `mysqld` from the command prompt when you first start the server with InnoDB enabled, not from the `mysqld_safe` wrapper or as a Windows service. When you run from a command prompt you see what `mysqld` prints and what is happening. On Unix, just invoke `mysqld`. On Windows, use the `--console` option.

When you start the MySQL server after initially configuring InnoDB in your option file, InnoDB creates your data files and log files, and prints something like this:

```
InnoDB: The first specified datafile /home/heikki/data/ibdata1
did not exist:
InnoDB: a new database to be created!
InnoDB: Setting file /home/heikki/data/ibdata1 size to 134217728
InnoDB: Database physically writes the file full: wait...
InnoDB: datafile /home/heikki/data/ibdata2 did not exist:
new to be created
InnoDB: Setting file /home/heikki/data/ibdata2 size to 262144000
InnoDB: Database physically writes the file full: wait...
InnoDB: Log file /home/heikki/data/logs/ib_logfile0 did not exist:
new to be created
InnoDB: Setting log file /home/heikki/data/logs/ib_logfile0 size
to 5242880
InnoDB: Log file /home/heikki/data/logs/ib_logfile1 did not exist:
new to be created
InnoDB: Setting log file /home/heikki/data/logs/ib_logfile1 size
to 5242880
InnoDB: Doublewrite buffer not found: creating new
InnoDB: Doublewrite buffer created
InnoDB: Creating foreign key constraint system tables
InnoDB: Foreign key constraint system tables created
InnoDB: Started
mysqld: ready for connections
```

At this point InnoDB has initialized its tablespace and log files. You can connect to the MySQL server with the usual MySQL client programs like `mysql`. When you shut down the MySQL server with `mysqladmin shutdown`, the output is like this:

```
010321 18:33:34 mysqld: Normal shutdown
010321 18:33:34 mysqld: Shutdown Complete
InnoDB: Starting shutdown...
InnoDB: Shutdown completed
```

You can look at the data file and log directories and you see the files created there. When MySQL is started again, the data files and log files have been created already, so the output is much briefer:

```
InnoDB: Started
mysqld: ready for connections
```

If you add the `innodb_file_per_table` option to `my.cnf`, InnoDB stores each table in its own `.ibd` file in the same MySQL database directory where the `.frm` file is created. See [Section 13.5.3.1, “Using Per-Table Tablespaces”](#).

13.5.5.1. Dealing with InnoDB Initialization Problems

If InnoDB prints an operating system error during a file operation, usually the problem has one of the following causes:

- You did not create the InnoDB data file directory or the InnoDB log directory.
- `mysqld` does not have access rights to create files in those directories.
- `mysqld` cannot read the proper `my.cnf` or `my.ini` option file, and consequently does not see the options that you specified.
- The disk is full or a disk quota is exceeded.

- You have created a subdirectory whose name is equal to a data file that you specified, so the name cannot be used as a filename.
- There is a syntax error in the `innodb_data_home_dir` or `innodb_data_file_path` value.

If something goes wrong when **InnoDB** attempts to initialize its tablespace or its log files, you should delete all files created by **InnoDB**. This means all `ibdata` files and all `ib_logfile` files. In case you have already created some **InnoDB** tables, delete the corresponding `.frm` files for these tables (and any `.ibd` files if you are using multiple tablespaces) from the MySQL database directories as well. Then you can try the **InnoDB** database creation again. It is best to start the MySQL server from a command prompt so that you see what is happening.

13.5.6. Creating and Using **InnoDB** Tables

To create an **InnoDB** table, specify an `ENGINE = InnoDB` option in the `CREATE TABLE` statement:

```
CREATE TABLE customers (a INT, b CHAR (20), INDEX (a)) ENGINE=InnoDB;
```

The statement creates a table and an index on column `a` in the **InnoDB** tablespace that consists of the data files that you specified in `my.cnf`. In addition, MySQL creates a file `customers.frm` in the `test` directory under the MySQL database directory. Internally, **InnoDB** adds an entry for the table to its own data dictionary. The entry includes the database name. For example, if `test` is the database in which the `customers` table is created, the entry is for `'test/customers'`. This means you can create a table of the same name `customers` in some other database, and the table names do not collide inside **InnoDB**.

You can query the amount of free space in the **InnoDB** tablespace by issuing a `SHOW TABLE STATUS` statement for any **InnoDB** table. The amount of free space in the tablespace appears in the `Comment` section in the output of `SHOW TABLE STATUS`. For example:

```
SHOW TABLE STATUS FROM test LIKE 'customers'
```

Note that the statistics `SHOW` displays for **InnoDB** tables are only approximate. They are used in SQL optimization. Table and index reserved sizes in bytes are accurate, though.

13.5.6.1. How to Use Transactions in **InnoDB** with Different APIs

By default, each client that connects to the MySQL server begins with autocommit mode enabled, which automatically commits every SQL statement as you execute it. To use multiple-statement transactions, you can switch autocommit off with the SQL statement `SET AUTOCOMMIT = 0` and use `COMMIT` and `ROLLBACK` to commit or roll back your transaction. If you want to leave autocommit on, you can enclose your transactions within `START TRANSACTION` and either `COMMIT` or `ROLLBACK`. The following example shows two transactions. The first is committed; the second is rolled back.

```
shell> mysql test

mysql> CREATE TABLE CUSTOMER (A INT, B CHAR (20), INDEX (A))
-> ENGINE=InnoDB;
Query OK, 0 rows affected (0.00 sec)
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO CUSTOMER VALUES (10, 'Heikki');
Query OK, 1 row affected (0.00 sec)
mysql> COMMIT;
Query OK, 0 rows affected (0.00 sec)
mysql> SET AUTOCOMMIT=0;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO CUSTOMER VALUES (15, 'John');
Query OK, 1 row affected (0.00 sec)
mysql> ROLLBACK;
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT * FROM CUSTOMER;
+-----+-----+
| A     | B     |
+-----+-----+
| 10    | Heikki |
+-----+-----+
1 row in set (0.00 sec)
mysql>
```

In APIs such as PHP, Perl DBI, JDBC, ODBC, or the standard C call interface of MySQL, you can send transaction control statements such as `COMMIT` to the MySQL server as strings just like any other SQL statements such as `SELECT` or `INSERT`. Some APIs also offer separate special transaction commit and rollback functions or methods.

13.5.6.2. Converting MyISAM Tables to InnoDB

Important: Do not convert MySQL system tables in the `mysql` database (such as `user` or `host`) to the `InnoDB` type. This is an unsupported operation. The system tables must always be of the `MyISAM` type.

If you want all your (non-system) tables to be created as `InnoDB` tables, you can simply add the line `default-storage-engine=innodb` to the `[mysqld]` section of your server option file.

`InnoDB` does not have a special optimization for separate index creation the way the `MyISAM` storage engine does. Therefore, it does not pay to export and import the table and create indexes afterward. The fastest way to alter a table to `InnoDB` is to do the inserts directly to an `InnoDB` table. That is, use `ALTER TABLE ... ENGINE=INNODB`, or create an empty `InnoDB` table with identical definitions and insert the rows with `INSERT INTO ... SELECT * FROM ...`.

If you have `UNIQUE` constraints on secondary keys, you can speed up a table import by turning off the uniqueness checks temporarily during the import operation:

```
SET UNIQUE_CHECKS=0;
... import operation ...
SET UNIQUE_CHECKS=1;
```

For big tables, this saves a lot of disk I/O because `InnoDB` can then use its insert buffer to write secondary index records as a batch. Be certain that the data contains no duplicate keys. `UNIQUE_CHECKS` allows but does not require storage engines to ignore duplicate keys.

To get better control over the insertion process, it might be good to insert big tables in pieces:

```
INSERT INTO newtable SELECT * FROM oldtable
WHERE yourkey > something AND yourkey <= somethingelse;
```

After all records have been inserted, you can rename the tables.

During the conversion of big tables, you should increase the size of the `InnoDB` buffer pool to reduce disk I/O. Do not use more than 80% of the physical memory, though. You can also increase the sizes of the `InnoDB` log files.

Make sure that you do not fill up the tablespace: `InnoDB` tables require a lot more disk space than `MyISAM` tables. If an `ALTER TABLE` operation runs out of space, it starts a rollback, and that can take hours if it is disk-bound. For inserts, `InnoDB` uses the insert buffer to merge secondary index records to indexes in batches. That saves a lot of disk I/O. For rollback, no such mechanism is used, and the rollback can take 30 times longer than the insertion.

In the case of a runaway rollback, if you do not have valuable data in your database, it may be advisable to kill the database process rather than wait for millions of disk I/O operations to complete. For the complete procedure, see [Section 13.5.8.1, “Forcing InnoDB Recovery”](#).

13.5.6.3. How AUTO_INCREMENT Handling Works in InnoDB

Beginning with MySQL 5.1.22, `InnoDB` provides a locking strategy that significantly improves scalability and performance of SQL statements that add rows to tables with `AUTO_INCREMENT` columns. This section provides background information on the original (“traditional”) implementation of auto-increment locking in `InnoDB`, explains the configurable locking mechanism, documents the parameter for configuring the mechanism, and describes its behavior and interaction with replication.

13.5.6.3.1. “Traditional” InnoDB Auto-Increment Locking

The original implementation of auto-increment handling in `InnoDB` uses the following strategy to prevent problems when using the binary log for statement-based replication or for certain recovery scenarios.

If you specify an `AUTO_INCREMENT` column for an `InnoDB` table, the table handle in the `InnoDB` data dictionary contains a special counter called the auto-increment counter that is used in assigning new values for the column. This counter is stored only in main memory, not on disk.

`InnoDB` uses the following algorithm to initialize the auto-increment counter for a table `t` that contains an `AUTO_INCREMENT` column named `ai_col`: After a server startup, for the first insert into a table `t`, `InnoDB` executes the equivalent of this statement:

```
SELECT MAX(ai_col) FROM t FOR UPDATE;
```

`InnoDB` increments by one the value retrieved by the statement and assigns it to the column and to the auto-increment counter for the

table. If the table is empty, **InnoDB** uses the value **1**. If a user invokes a **SHOW TABLE STATUS** statement that displays output for the table **t** and the auto-increment counter has not been initialized, **InnoDB** initializes but does not increment the value and stores it for use by later inserts. This initialization uses a normal exclusive-locking read on the table and the lock lasts to the end of the transaction.

InnoDB follows the same procedure for initializing the auto-increment counter for a freshly created table.

After the auto-increment counter has been initialized, if a user does not explicitly specify a value for an **AUTO_INCREMENT** column, **InnoDB** increments the counter by one and assigns the new value to the column. If the user inserts a row that explicitly specifies the column value, and the value is bigger than the current counter value, the counter is set to the specified column value.

When accessing the auto-increment counter, **InnoDB** uses a special table-level **AUTO-INC** lock that it keeps to the end of the current SQL statement, not to the end of the transaction. The special lock release strategy was introduced to improve concurrency for inserts into a table containing an **AUTO_INCREMENT** column. Nevertheless, two transactions cannot have the **AUTO-INC** lock on the same table simultaneously, which can have a performance impact if the **AUTO-INC** lock is held for a long time. That might be the case for a statement such as **INSERT INTO t1 ... SELECT ... FROM t2** that inserts all rows from one table into another.

InnoDB uses the in-memory auto-increment counter as long as the server runs. When the server is stopped and restarted, **InnoDB** reinitializes the counter for each table for the first **INSERT** to the table, as described earlier.

You may see gaps in the sequence of values assigned to the **AUTO_INCREMENT** column if you roll back transactions that have generated numbers using the counter.

If a user specifies **NULL** or **0** for the **AUTO_INCREMENT** column in an **INSERT**, **InnoDB** treats the row as if the value had not been specified and generates a new value for it.

The behavior of the auto-increment mechanism is not defined if a user assigns a negative value to the column or if the value becomes bigger than the maximum integer that can be stored in the specified integer type.

An **AUTO_INCREMENT** column must be the first column listed if it is part of a multiple-column index in an **InnoDB** table.

InnoDB supports the **AUTO_INCREMENT = N** table option in **CREATE TABLE** and **ALTER TABLE** statements, to set the initial counter value or alter the current counter value. The effect of this option is canceled by a server restart, for reasons discussed earlier in this section.

13.5.6.3.2. Configurable **InnoDB** Auto-Increment Locking

As described in the previous section, **InnoDB** uses a special lock called the **AUTO-INC** table-level lock for inserts into tables with **AUTO_INCREMENT** columns. This lock is normally held to the end of the statement (not to the end of the transaction), to ensure that auto-increment numbers are assigned in a predictable and repeatable order for a given sequence of **INSERT** statements.

In the case of statement-based replication, this means that when a SQL statement is replicated on a slave server, the same values are used for the auto-increment column as on the master server. The result of execution of multiple **INSERT** statements is deterministic, and the slave reproduces the same data as on the master. If auto-increment values generated by multiple **INSERT** statements were interleaved, the result of two concurrent **INSERT** statements would be non-deterministic, and could not reliably be propagated to a slave server using statement-based replication.

To make this clear, consider an example that uses this table:

```
CREATE TABLE t1 (
  c1 INT(11) NOT NULL AUTO_INCREMENT,
  c2 VARCHAR(10) DEFAULT NULL,
  PRIMARY KEY (c1)
) ENGINE=InnoDB;
```

Suppose that there are two transactions running, each inserting rows into a table with an **AUTO_INCREMENT** column. One transaction is using an **INSERT ... SELECT** statement that inserts 1000 rows, and another is using a simple **INSERT** statement that inserts one row:

```
Tx1: INSERT INTO t1 (c2) SELECT 1000 rows from another table ...
Tx2: INSERT INTO t1 (c2) VALUES ('xxx');
```

InnoDB cannot tell in advance how many rows will be retrieved from the **SELECT** in the **INSERT** statement in Tx1, and it assigns the auto-increment values one at a time as the statement proceeds. With a table-level lock, held to the end of the statement, only one **INSERT** statement referring to table **t1** can execute at a time, and the generation of auto-increment numbers by different statements is not interleaved. The auto-increment value generated by the Tx1 **INSERT ... SELECT** statement will be consecutive, and the (single) auto-increment value used by the **INSERT** statement in Tx2 will either be smaller or larger than all those used for Tx1, depending on which statement executes first.

As long as the SQL statements execute in the same order when replayed from the binary log (when using statement-based replication, or in recovery scenarios), the results will be the same as they were when Tx1 and Tx2 first ran. Thus, table-level locks held until the end of a statement make **INSERT** statements using auto-increment safe for use with statement-based replication. However, those locks limit concurrency and scalability when multiple transactions are executing insert statements at the same time.

In the preceding example, if there were no table-level lock, the value of the auto-increment column used for the **INSERT** in Tx2 depends on precisely when the statement executes. If the **INSERT** of Tx2 executes while the **INSERT** of Tx1 is running (rather than before it starts or after it completes), the specific auto-increment values assigned by the two **INSERT** statements are non-deterministic, and may vary from run to run.

As of MySQL 5.1.22, **InnoDB** can avoid using the table-level AUTO-INC lock for a class of **INSERT** statements where the number of rows is known in advance, and still preserve deterministic execution and safety for statement-based replication. Further, if you are not using the binary log to replay SQL statements as part of recovery or replication, you can entirely eliminate use of the AUTO-INC table-level lock for even greater concurrency and performance—at the cost of permitting gaps in auto-increment numbers assigned by a statement and potentially having the numbers assigned by concurrently executing statements interleaved.

For **INSERT** statements where the number of rows to be inserted is known at the beginning of processing the statement, **InnoDB** quickly allocates the required number of auto-increment values without taking any lock, but only if there is no concurrent session already holding the table-level lock AUTO-INC lock (because that other statement will be allocating auto-increment values one-by-one as it proceeds). More precisely, such an **INSERT** statement obtains auto-increment values under the control of a mutex (a light-weight lock) that is *not* held until the statement completes, but only for the duration of the allocation process.

This new locking scheme allows much greater scalability, but it does introduce some subtle differences in how auto-increment values are assigned compared to the original mechanism. To describe the way auto-increment works in **InnoDB**, the following discussion defines some terms, and explains how **InnoDB** behaves using different settings of the new `innodb_autoinc_lock_mode` configuration parameter. Additional considerations are described following the explanation of auto-increment locking behavior.

First, some definitions:

- “**INSERT-like**” statements

All statements that generate new rows in a table, including **INSERT**, **INSERT ... SELECT**, **REPLACE**, **REPLACE ... SELECT**, and **LOAD DATA**.

- “Simple inserts”

Statements for which the number of rows to be inserted can be determined in advance (when the statement is initially processed). This includes single-row and multiple-row **INSERT**, **INSERT ... ON DUPLICATE KEY UPDATE**, and **REPLACE** statements that do not have a nested subquery.

- “Bulk inserts”

Statements for which the number of rows to be inserted (and the number of required auto-increment values) is not known in advance. This includes **INSERT ... SELECT**, **REPLACE ... SELECT**, and **LOAD DATA** statements. **InnoDB** will assign new values for the **AUTO_INCREMENT** column one at a time as each row is processed.

- “Mixed-mode inserts”

These are “simple insert” statements that specify the auto-increment value for some (but not all) of the new rows. An example follows, where **c1** is an **AUTO_INCREMENT** column of table **t1**:

```
INSERT INTO t1 (c1,c2) VALUES (1, 'a'), (NULL, 'b'), (5, 'c'), (NULL, 'd');
```

Beginning with MySQL 5.1.22, there is a new configuration parameter that controls how **InnoDB** uses locking when generating values for **AUTO_INCREMENT** columns. This parameter can be set using the `--innodb-autoinc-lock-mode` option at `mysqld` startup, or at runtime by setting the global `innodb_autoinc_lock_mode` system variable. Although this variable can be changed at runtime, the behavior is undefined if you do so while transactions that generate auto-increment values are executing.

In general, if you encounter problems with the way auto-increment works (which will most likely involve replication), you can force use of the original behavior by setting the lock mode to 0.

There are three possible settings for the `innodb_autoinc_lock_mode` parameter:

- `innodb_autoinc_lock_mode = 0` (“traditional” lock mode)

This lock mode provides the same behavior as before `innodb_autoinc_lock_mode` existed. For all “`INSERT`-like” statements, a special AUTO-INC table-level lock is obtained and held to the end of the statement. This assures that the auto-increment values assigned by any given statement are consecutive (although “gaps” can exist within a table if a transaction that generated auto-increment values is rolled back, as discussed later).

This lock mode is provided only for backward compatibility and performance testing. There is little reason to use this lock mode unless you use “mixed-mode inserts” and care about the minor difference in semantics described later.

- `innodb_autoinc_lock_mode = 1` (“consecutive” lock mode)

This is the default lock mode. In this mode, “bulk inserts” use the special table-level AUTO-INC table-level lock and holds it until the end of the statement. This applies to all `INSERT ... SELECT`, `REPLACE ... SELECT`, and `LOAD DATA` statements. Only one statement holding the AUTO-INC lock can execute at a time.

With this lock mode, “simple inserts” (only) use a new locking model where a light-weight mutex is used during the allocation of auto-increment values, and no AUTO-INC table-level lock is used, unless an AUTO-INC lock is held by another transaction. If another transaction does hold an AUTO-INC lock, a “simple insert” waits for the AUTO-INC lock, as if it too were a “bulk insert.”

This lock mode ensures that, in the presence of `INSERT` statements where the number of rows is not known in advance (and where auto-increment numbers are assigned as the statement progresses), all auto-increment values assigned by any “`INSERT`-like” statement are consecutive, and operations are safe for statement-based replication.

Simply put, the important impact of this lock mode is significantly better scalability. This mode is safe for use with statement-based replication. Further, as with “traditional” lock mode, auto-increment numbers assigned by any given statement are *consecutive*. In this mode, there is *no change* in semantics compared to “traditional” mode for any statement that uses auto-increment, with one minor exception.

The exception is for “mixed-mode inserts”, where the user provides explicit values for an `AUTO_INCREMENT` column for some, but not all, rows in a multiple-row “simple insert.” For such inserts, `InnoDB` will allocate more auto-increment values than the number of rows to be inserted. However, all values automatically assigned are consecutively generated (and thus higher than) the auto-increment value generated by the most recently executed previous statement. “Excess” numbers are lost.

- `innodb_autoinc_lock_mode = 2` (“interleaved” lock mode)

In this lock mode, no “`INSERT`-like” statements use the table-level AUTO-INC lock, and multiple statements can execute at the same time. This is the fastest and most scalable lock mode, but it is *not safe* when using statement-based replication or recovery scenarios when SQL statements are replayed from the binary log.

In this lock mode, auto-increment values are guaranteed to be unique and monotonically increasing across all concurrently executing “`INSERT`-like” statements. However, because multiple statements can be generating numbers at the same time (that is, allocation of numbers is *interleaved* across statements), the values generated for the rows inserted by any given statement may not be consecutive.

If the only statements executing are “simple inserts” where the number of rows to be inserted is known ahead of time, there will be no gaps in the numbers generated for a single statement, except for “mixed-mode inserts.” However, when “bulk inserts” are executed, there may be gaps in the auto-increment values assigned by any given statement.

The auto-increment locking modes provided by `innodb_autoinc_lock_mode` have several usage implications:

- Using auto-increment with replication

If you are using statement-based replication, you should set `innodb_autoinc_lock_mode` to 0 or 1 and use the same value on the master and its slaves. Auto-increment values are not ensured to be the same on the slaves as on the master if you use `innodb_autoinc_lock_mode = 2` (“interleaved”) or configurations where the master and slaves do not use the same lock mode.

If you are using row-based replication, all of the auto-increment lock modes are safe. Row-based replication is not sensitive to the order of execution of the SQL statements.

- “Lost” auto-increment values and sequence gaps

In all lock modes (0, 1, and 2), if a transaction that generated auto-increment values rolls back, those auto-increment values are “lost.” Once a value is generated for an auto-increment column, it cannot be rolled back, whether or not the “`INSERT`-like” state-

ment is completed, and whether or not the containing transaction is rolled back. Such lost values are not reused. Thus, there may be gaps in the values stored in an `AUTO_INCREMENT` column of a table.

- Auto-increment values assigned by “mixed-mode inserts”

Consider a “mixed-mode insert,” where a “simple insert” specifies the auto-increment value for some (but not all) resulting rows. Such a statement will behave differently in lock modes 0, 1, and 2. For example, assume `c1` is an `AUTO_INCREMENT` column of table `t1`, and that the most recent automatically generated sequence number is 100. Consider the following “mixed-mode insert” statement:

```
INSERT INTO t1 (c1,c2) VALUES (1, 'a'), (NULL, 'b'), (5, 'c'), (NULL, 'd');
```

With `innodb_autoinc_lock_mode` set to 0 (“traditional”), the four new rows will be:

c1	c2
1	a
101	b
5	c
102	d

The next available auto-increment value will be 103 because the auto-increment values are allocated one at a time, not all at once at the beginning of statement execution. This result is true whether or not there are concurrently executing “`INSERT`-like” statements (of any type).

With `innodb_autoinc_lock_mode` set to 1 (“consecutive”), the four new rows will also be:

c1	c2
1	a
101	b
5	c
102	d

However, in this case, the next available auto-increment value will be 105, not 103 because four auto-increment values are allocated at the time the statement is processed, but only two are used. This result is true whether or not there are concurrently executing “`INSERT`-like” statements (of any type).

With `innodb_autoinc_lock_mode` set to mode 2 (“interleaved”), the four new rows will be:

c1	c2
1	a
x	b
5	c
y	d

The values of `x` and `y` will be unique and larger than any previously generated rows. However, the specific values of `x` and `y` will depend on the number of auto-increment values generated by concurrently executing statements.

Finally, consider the following statement, issued when the most-recently generated sequence number was the value 4:

```
INSERT INTO t1 (c1,c2) VALUES (1, 'a'), (NULL, 'b'), (5, 'c'), (NULL, 'd');
```

With any `innodb_autoinc_lock_mode` setting, this statement will generate a duplicate-key error 23000 (`Can't write; duplicate key in table`) because 5 will be allocated for the row `(NULL, 'b')` and insertion of the row `(5, 'c')` will fail.

- Gaps in auto-increment values for “bulk inserts”

With `innodb_autoinc_lock_mode` set to 0 (“traditional”) or 1 (“consecutive”), the auto-increment values generated by any given statement will be consecutive, without gaps, because the table-level AUTO-INC lock is held until the end of the statement, and only one such statement can execute at a time.

With `innodb_autoinc_lock_mode` set to 2 (“interleaved”), there may be gaps in the auto-increment values generated by “bulk inserts,” but only if there are concurrently executing “**INSERT**-like” statements.

13.5.6.4. FOREIGN KEY Constraints

InnoDB also supports foreign key constraints. The syntax for a foreign key constraint definition in **InnoDB** looks like this:

```
[CONSTRAINT symbol] FOREIGN KEY [id] (index_col_name, ...)
REFERENCES tbl_name (index_col_name, ...)
[ON DELETE {RESTRICT | CASCADE | SET NULL | NO ACTION}]
[ON UPDATE {RESTRICT | CASCADE | SET NULL | NO ACTION}]
```

Foreign keys definitions are subject to the following conditions:

- Both tables must be **InnoDB** tables and they must not be **TEMPORARY** tables.
- Corresponding columns in the foreign key and the referenced key must have similar internal data types inside **InnoDB** so that they can be compared without a type conversion. *The size and sign of integer types must be the same.* The length of string types need not be the same. For non-binary (character) string columns, the character set and collation must be the same.
- In the referencing table, there must be an index where the foreign key columns are listed as the *first* columns in the same order. Such an index is created on the referencing table automatically if it does not exist.
- In the referenced table, there must be an index where the referenced columns are listed as the *first* columns in the same order.
- Index prefixes on foreign key columns are not supported. One consequence of this is that **BLOB** and **TEXT** columns cannot be included in a foreign key, because indexes on those columns must always include a prefix length.
- If the **CONSTRAINT *symbol*** clause is given, the *symbol* value must be unique in the database. If the clause is not given, **InnoDB** creates the name automatically.

InnoDB rejects any **INSERT** or **UPDATE** operation that attempts to create a foreign key value in a child table if there is no a matching candidate key value in the parent table. The action **InnoDB** takes for any **UPDATE** or **DELETE** operation that attempts to update or delete a candidate key value in the parent table that has some matching rows in the child table is dependent on the *referential action* specified using **ON UPDATE** and **ON DELETE** subclauses of the **FOREIGN KEY** clause. When the user attempts to delete or update a row from a parent table, and there are one or more matching rows in the child table, **InnoDB** supports five options regarding the action to be taken:

- **CASCADE**: Delete or update the row from the parent table and automatically delete or update the matching rows in the child table. Both **ON DELETE CASCADE** and **ON UPDATE CASCADE** are supported. Between two tables, you should not define several **ON UPDATE CASCADE** clauses that act on the same column in the parent table or in the child table.
- **SET NULL**: Delete or update the row from the parent table and set the foreign key column or columns in the child table to **NULL**. This is valid only if the foreign key columns do not have the **NOT NULL** qualifier specified. Both **ON DELETE SET NULL** and **ON UPDATE SET NULL** clauses are supported.

If you specify a **SET NULL** action, *make sure that you have not declared the columns in the child table as **NOT NULL**.*

- **NO ACTION**: In standard SQL, **NO ACTION** means *no action* in the sense that an attempt to delete or update a primary key value is not allowed to proceed if there is a related foreign key value in the referenced table. **InnoDB** rejects the delete or update operation for the parent table.
- **RESTRICT**: Rejects the delete or update operation for the parent table. **NO ACTION** and **RESTRICT** are the same as omitting the **ON DELETE** or **ON UPDATE** clause. (Some database systems have deferred checks, and **NO ACTION** is a deferred check. In MySQL, foreign key constraints are checked immediately, so **NO ACTION** and **RESTRICT** are the same.)
- **SET DEFAULT**: This action is recognized by the parser, but **InnoDB** rejects table definitions containing **ON DELETE SET DEFAULT** or **ON UPDATE SET DEFAULT** clauses.

Note that **InnoDB** supports foreign key references within a table. In these cases, “child table records” really refers to dependent records

within the same table.

InnoDB requires indexes on foreign keys and referenced keys so that foreign key checks can be fast and not require a table scan. The index on the foreign key is created automatically. This is in contrast to some older versions, in which indexes had to be created explicitly or the creation of foreign key constraints would fail.

If MySQL reports an error number 1005 from a **CREATE TABLE** statement, and the error message refers to `errno 150`, table creation failed because a foreign key constraint was not correctly formed. Similarly, if an **ALTER TABLE** fails and it refers to `errno 150`, that means a foreign key definition would be incorrectly formed for the altered table. You can use **SHOW ENGINE INNODB STATUS** to display a detailed explanation of the most recent **InnoDB** foreign key error in the server.

Note

InnoDB does not check foreign key constraints on those foreign key or referenced key values that contain a **NULL** column.

Note

Currently, triggers are not activated by cascaded foreign key actions.

You cannot create a table with a column name that matches the name of an internal **InnoDB** column (including **DB_ROW_ID**, **DB_TRX_ID**, **DB_ROLL_PTR** and **DB_MIX_ID**). In versions of MySQL before 5.1.10 this would cause a crash, since 5.1.10 the server will report error 1005 and refers to `errno -1` in the error message.

Deviation from SQL standards: If there are several rows in the parent table that have the same referenced key value, **InnoDB** acts in foreign key checks as if the other parent rows with the same key value do not exist. For example, if you have defined a **RESTRICT** type constraint, and there is a child row with several parent rows, **InnoDB** does not allow the deletion of any of those parent rows.

InnoDB performs cascading operations through a depth-first algorithm, based on records in the indexes corresponding to the foreign key constraints.

Deviation from SQL standards: A **FOREIGN KEY** constraint that references a non-**UNIQUE** key is not standard SQL. It is an **InnoDB** extension to standard SQL.

Deviation from SQL standards: If **ON UPDATE CASCADE** or **ON UPDATE SET NULL** recurses to update the *same table* it has previously updated during the cascade, it acts like **RESTRICT**. This means that you cannot use self-referential **ON UPDATE CASCADE** or **ON UPDATE SET NULL** operations. This is to prevent infinite loops resulting from cascaded updates. A self-referential **ON DELETE SET NULL**, on the other hand, is possible, as is a self-referential **ON DELETE CASCADE**. Cascading operations may not be nested more than 15 levels deep.

Deviation from SQL standards: Like MySQL in general, in an SQL statement that inserts, deletes, or updates many rows, **InnoDB** checks **UNIQUE** and **FOREIGN KEY** constraints row-by-row. According to the SQL standard, the default behavior should be deferred checking. That is, constraints are only checked after the *entire SQL statement* has been processed. Until **InnoDB** implements deferred constraint checking, some things will be impossible, such as deleting a record that refers to itself via a foreign key.

Here is a simple example that relates **parent** and **child** tables through a single-column foreign key:

```
CREATE TABLE parent (id INT NOT NULL,
                     PRIMARY KEY (id)
) ENGINE=INNODB;
CREATE TABLE child (id INT, parent_id INT,
                    INDEX par_ind (parent_id),
                    FOREIGN KEY (parent_id) REFERENCES parent(id)
                    ON DELETE CASCADE
) ENGINE=INNODB;
```

A more complex example in which a **product_order** table has foreign keys for two other tables. One foreign key references a two-column index in the **product** table. The other references a single-column index in the **customer** table:

```
CREATE TABLE product (category INT NOT NULL, id INT NOT NULL,
                      price DECIMAL,
                      PRIMARY KEY(category, id)) ENGINE=INNODB;
CREATE TABLE customer (id INT NOT NULL,
                       PRIMARY KEY (id)) ENGINE=INNODB;
CREATE TABLE product_order (no INT NOT NULL AUTO_INCREMENT,
                             product_category INT NOT NULL,
                             product_id INT NOT NULL,
                             customer_id INT NOT NULL,
                             PRIMARY KEY(no),
                             INDEX (product_category, product_id),
                             FOREIGN KEY (product_category, product_id)
```

```
REFERENCES product(category, id)
ON UPDATE CASCADE ON DELETE RESTRICT,
INDEX (customer_id),
FOREIGN KEY (customer_id)
REFERENCES customer(id)) ENGINE=INNODB;
```

InnoDB allows you to add a new foreign key constraint to a table by using **ALTER TABLE**:

```
ALTER TABLE tbl_name
ADD [CONSTRAINT symbol] FOREIGN KEY [id] (index_col_name, ...)
REFERENCES tbl_name (index_col_name, ...)
[ON DELETE {RESTRICT | CASCADE | SET NULL | NO ACTION}]
[ON UPDATE {RESTRICT | CASCADE | SET NULL | NO ACTION}]
```

Remember to create the required indexes first. You can also add a self-referential foreign key constraint to a table using **ALTER TABLE**.

InnoDB also supports the use of **ALTER TABLE** to drop foreign keys:

```
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```

If the **FOREIGN KEY** clause included a **CONSTRAINT** name when you created the foreign key, you can refer to that name to drop the foreign key. Otherwise, the *fk_symbol* value is internally generated by **InnoDB** when the foreign key is created. To find out the symbol value when you want to drop a foreign key, use the **SHOW CREATE TABLE** statement. For example:

```
mysql> SHOW CREATE TABLE ibtest11c\G
***** 1. row *****
      Table: ibtest11c
Create Table: CREATE TABLE `ibtest11c` (
  `A` int(11) NOT NULL auto_increment,
  `D` int(11) NOT NULL default '0',
  `B` varchar(200) NOT NULL default '',
  `C` varchar(175) default NULL,
  PRIMARY KEY (`A`,`D`,`B`),
  KEY `B` (`B`,`C`),
  KEY `C` (`C`),
  CONSTRAINT `0_38775` FOREIGN KEY (`A`,`D`)
REFERENCES `ibtest11a` (`A`,`D`)
ON DELETE CASCADE ON UPDATE CASCADE,
  CONSTRAINT `0_38776` FOREIGN KEY (`B`,`C`)
REFERENCES `ibtest11a` (`B`,`C`)
ON DELETE CASCADE ON UPDATE CASCADE
) ENGINE=INNODB CHARSET=latin1
1 row in set (0.01 sec)

mysql> ALTER TABLE ibtest11c DROP FOREIGN KEY `0_38775`;
```

You cannot add a foreign key and drop a foreign key in separate clauses of a single **ALTER TABLE** statement. Separate statements are required.

If **ALTER TABLE** for an **InnoDB** table results in changes to column values (for example, because a column is truncated), **InnoDB**'s **FOREIGN KEY** constraint checks do not notice possible violations caused by changing the values.

The **InnoDB** parser allows table and column identifiers in a **FOREIGN KEY ... REFERENCES ...** clause to be quoted within backticks. (Alternatively, double quotes can be used if the **ANSI_QUOTES** SQL mode is enabled.) The **InnoDB** parser also takes into account the setting of the **lower_case_table_names** system variable.

InnoDB returns a table's foreign key definitions as part of the output of the **SHOW CREATE TABLE** statement:

```
SHOW CREATE TABLE tbl_name;
```

mysqldump also produces correct definitions of tables to the dump file, and does not forget about the foreign keys.

You can also display the foreign key constraints for a table like this:

```
SHOW TABLE STATUS FROM db_name LIKE 'tbl_name';
```

The foreign key constraints are listed in the **Comment** column of the output.

When performing foreign key checks, **InnoDB** sets shared row-level locks on child or parent records it has to look at. **InnoDB** checks foreign key constraints immediately; the check is not deferred to transaction commit.

To make it easier to reload dump files for tables that have foreign key relationships, `mysqldump` automatically includes a statement in the dump output to set `FOREIGN_KEY_CHECKS` to 0. This avoids problems with tables having to be reloaded in a particular order when the dump is reloaded. It is also possible to set this variable manually:

```
mysql> SET FOREIGN_KEY_CHECKS = 0;
mysql> SOURCE dump_file_name;
mysql> SET FOREIGN_KEY_CHECKS = 1;
```

This allows you to import the tables in any order if the dump file contains tables that are not correctly ordered for foreign keys. It also speeds up the import operation. Setting `FOREIGN_KEY_CHECKS` to 0 can also be useful for ignoring foreign key constraints during `LOAD DATA` and `ALTER TABLE` operations. However, even if `FOREIGN_KEY_CHECKS=0`, InnoDB does not allow the creation of a foreign key constraint where a column references a non-matching column type. Also, if an InnoDB table has foreign key constraints, `ALTER TABLE` cannot be used to change the table to use another storage engine. To alter the storage engine, you must drop any foreign key constraints first.

InnoDB does not allow you to drop a table that is referenced by a `FOREIGN KEY` constraint, unless you do `SET FOREIGN_KEY_CHECKS=0`. When you drop a table, the constraints that were defined in its create statement are also dropped.

If you re-create a table that was dropped, it must have a definition that conforms to the foreign key constraints referencing it. It must have the right column names and types, and it must have indexes on the referenced keys, as stated earlier. If these are not satisfied, MySQL returns error number 1005 and refers to errno 150 in the error message.

13.5.6.5. InnoDB and MySQL Replication

MySQL replication works for InnoDB tables as it does for MyISAM tables. It is also possible to use replication in a way where the storage engine on the slave is not the same as the original storage engine on the master. For example, you can replicate modifications to an InnoDB table on the master to a MyISAM table on the slave.

To set up a new slave for a master, you have to make a copy of the InnoDB tablespace and the log files, as well as the `.frm` files of the InnoDB tables, and move the copies to the slave. If the `innodb_file_per_table` variable is enabled, you must also copy the `.ibd` files as well. For the proper procedure to do this, see [Section 13.5.8, “Backing Up and Recovering an InnoDB Database”](#).

If you can shut down the master or an existing slave, you can take a cold backup of the InnoDB tablespace and log files and use that to set up a slave. To make a new slave without taking down any server you can also use the non-free (commercial) [InnoDB Hot Backup tool](#).

You cannot set up replication for InnoDB using the `LOAD TABLE FROM MASTER` statement, which works only for MyISAM tables. There are two possible workarounds:

- Dump the table on the master and import the dump file into the slave.
- Use `ALTER TABLE tbl_name ENGINE=MyISAM` on the master before setting up replication with `LOAD TABLE tbl_name FROM MASTER`, and then use `ALTER TABLE` to convert the master table back to InnoDB afterward. However, this should not be done for tables that have foreign key definitions because the definitions will be lost.

Transactions that fail on the master do not affect replication at all. MySQL replication is based on the binary log where MySQL writes SQL statements that modify data. A transaction that fails (for example, because of a foreign key violation, or because it is rolled back) is not written to the binary log, so it is not sent to slaves. See [Section 12.4.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”](#).

13.5.7. Adding and Removing InnoDB Data and Log Files

This section describes what you can do when your InnoDB tablespace runs out of room or when you want to change the size of the log files.

The easiest way to increase the size of the InnoDB tablespace is to configure it from the beginning to be auto-extending. Specify the `autoextend` attribute for the last data file in the tablespace definition. Then InnoDB increases the size of that file automatically in 8MB increments when it runs out of space. The increment size can be changed by setting the value of the `innodb_autoextend_increment` system variable, which is measured in MB.

Alternatively, you can increase the size of your tablespace by adding another data file. To do this, you have to shut down the MySQL server, change the tablespace configuration to add a new data file to the end of `innodb_data_file_path`, and start the server again.

If your last data file was defined with the keyword `autoextend`, the procedure for reconfiguring the tablespace must take into account the size to which the last data file has grown. Obtain the size of the data file, round it down to the closest multiple of 1024×1024 bytes (= 1MB), and specify the rounded size explicitly in `innodb_data_file_path`. Then you can add another data file. Remember that only the last data file in the `innodb_data_file_path` can be specified as auto-extending.

As an example, assume that the tablespace has just one auto-extending data file `ibdata1`:

```
innodb_data_home_dir =  
innodb_data_file_path = /ibdata/ibdata1:10M:autoextend
```

Suppose that this data file, over time, has grown to 988MB. Here is the configuration line after modifying the original data file to not be auto-extending and adding another auto-extending data file:

```
innodb_data_home_dir =  
innodb_data_file_path = /ibdata/ibdata1:988M;/disk2/ibdata2:50M:autoextend
```

When you add a new file to the tablespace configuration, make sure that it does not exist. **InnoDB** will create and initialize the file when you restart the server.

Currently, you cannot remove a data file from the tablespace. To decrease the size of your tablespace, use this procedure:

1. Use `mysqldump` to dump all your **InnoDB** tables.
2. Stop the server.
3. Remove all the existing tablespace files.
4. Configure a new tablespace.
5. Restart the server.
6. Import the dump files.

If you want to change the number or the size of your **InnoDB** log files, use the following instructions. The procedure to use depends on the value of `innodb_fast_shutdown`:

- If `innodb_fast_shutdown` is not set to 2: You must stop the MySQL server and make sure that it shuts down without errors (to ensure that there is no information for outstanding transactions in the logs). Then copy the old log files into a safe place just in case something went wrong in the shutdown and you need them to recover the tablespace. Delete the old log files from the log file directory, edit `my.cnf` to change the log file configuration, and start the MySQL server again. `mysqld` sees that no log files exist at startup and tells you that it is creating new ones.
- If `innodb_fast_shutdown` is set to 2: You should shut down the server, set `innodb_fast_shutdown` to 1, and restart the server. The server should be allowed to recover. Then you should shut down the server again and follow the procedure described in the preceding item to change **InnoDB** log file size. Set `innodb_fast_shutdown` back to 2 and restart the server.

13.5.8. Backing Up and Recovering an **InnoDB** Database

The key to safe database management is making regular backups.

InnoDB Hot Backup is an online backup tool you can use to backup your **InnoDB** database while it is running. **InnoDB Hot Backup** does not require you to shut down your database and it does not set any locks or disturb your normal database processing. **InnoDB Hot Backup** is a non-free (commercial) add-on tool with an annual license fee of €390 per computer on which the MySQL server is run. See the [InnoDB Hot Backup home page](#) for detailed information and screenshots.

If you are able to shut down your MySQL server, you can make a binary backup that consists of all files used by **InnoDB** to manage its tables. Use the following procedure:

1. Shut down your MySQL server and make sure that it shuts down without errors.

2. Copy all your data files (`ibdata` files and `.ibd` files) into a safe place.
3. Copy all your `ib_logfile` files to a safe place.
4. Copy your `my.cnf` configuration file or files to a safe place.
5. Copy all the `.frm` files for your `InnoDB` tables to a safe place.

Replication works with `InnoDB` tables, so you can use MySQL replication capabilities to keep a copy of your database at database sites requiring high availability.

In addition to making binary backups as just described, you should also regularly make dumps of your tables with `mysqldump`. The reason for this is that a binary file might be corrupted without you noticing it. Dumped tables are stored into text files that are human-readable, so spotting table corruption becomes easier. Also, because the format is simpler, the chance for serious data corruption is smaller. `mysqldump` also has a `--single-transaction` option that you can use to make a consistent snapshot without locking out other clients.

To be able to recover your `InnoDB` database to the present from the binary backup just described, you have to run your MySQL server with binary logging turned on. Then you can apply the binary log to the backup database to achieve point-in-time recovery:

```
mysqlbinlog yourhostname-bin.123 | mysql
```

To recover from a crash of your MySQL server, the only requirement is to restart it. `InnoDB` automatically checks the logs and performs a roll-forward of the database to the present. `InnoDB` automatically rolls back uncommitted transactions that were present at the time of the crash. During recovery, `mysqld` displays output something like this:

```
InnoDB: Database was not shut down normally.
InnoDB: Starting recovery from log files...
InnoDB: Starting log scan based on checkpoint at
InnoDB: log sequence number 0 13674004
InnoDB: Doing recovery: scanned up to log sequence number 0 13739520
InnoDB: Doing recovery: scanned up to log sequence number 0 13805056
InnoDB: Doing recovery: scanned up to log sequence number 0 13870592
InnoDB: Doing recovery: scanned up to log sequence number 0 13936128
...
InnoDB: Doing recovery: scanned up to log sequence number 0 20555264
InnoDB: Doing recovery: scanned up to log sequence number 0 20620800
InnoDB: Doing recovery: scanned up to log sequence number 0 20664692
InnoDB: 1 uncommitted transaction(s) which must be rolled back
InnoDB: Starting rollback of uncommitted transactions
InnoDB: Rolling back trx no 16745
InnoDB: Rolling back of trx no 16745 completed
InnoDB: Rollback of uncommitted transactions completed
InnoDB: Starting an apply batch of log records to the database...
InnoDB: Apply batch completed
InnoDB: Started
mysqld: ready for connections
```

If your database gets corrupted or your disk fails, you have to do the recovery from a backup. In the case of corruption, you should first find a backup that is not corrupted. After restoring the base backup, do the recovery from the binary log files using `mysqlbinlog` and `mysql` to restore the changes performed after the backup was made.

In some cases of database corruption it is enough just to dump, drop, and re-create one or a few corrupt tables. You can use the `CHECK TABLE` SQL statement to check whether a table is corrupt, although `CHECK TABLE` naturally cannot detect every possible kind of corruption. You can use `innodb_tablespace_monitor` to check the integrity of the file space management inside the tablespace files.

In some cases, apparent database page corruption is actually due to the operating system corrupting its own file cache, and the data on disk may be okay. It is best first to try restarting your computer. Doing so may eliminate errors that appeared to be database page corruption.

13.5.8.1. Forcing `InnoDB` Recovery

If there is database page corruption, you may want to dump your tables from the database with `SELECT INTO OUTFILE`. Usually, most of the data obtained in this way is intact. Even so, the corruption may cause `SELECT * FROM tbl_name` statements or `InnoDB` background operations to crash or assert, or even to cause `InnoDB` roll-forward recovery to crash. However, you can force the `InnoDB` storage engine to start up while preventing background operations from running, so that you are able to dump your tables. For example, you can add the following line to the `[mysqld]` section of your option file before restarting the server:

```
[mysqld]  
innodb_force_recovery = 4
```

The allowable non-zero values for `innodb_force_recovery` follow. A larger number includes all precautions of smaller numbers. If you are able to dump your tables with an option value of at most 4, then you are relatively safe that only some data on corrupt individual pages is lost. A value of 6 is more drastic because database pages are left in an obsolete state, which in turn may introduce more corruption into B-trees and other database structures.

- **1 (SRV_FORCE_IGNORE_CORRUPT)**

Let the server run even if it detects a corrupt page. Try to make `SELECT * FROM tbl_name` jump over corrupt index records and pages, which helps in dumping tables.

- **2 (SRV_FORCE_NO_BACKGROUND)**

Prevent the main thread from running. If a crash would occur during the purge operation, this recovery value prevents it.

- **3 (SRV_FORCE_NO_TRX_UNDO)**

Do not run transaction rollbacks after recovery.

- **4 (SRV_FORCE_NO_IBUF_MERGE)**

Prevent also insert buffer merge operations. If they would cause a crash, do not do them. Do not calculate table statistics.

- **5 (SRV_FORCE_NO_UNDO_LOG_SCAN)**

Do not look at undo logs when starting the database: `InnoDB` treats even incomplete transactions as committed.

- **6 (SRV_FORCE_NO_LOG_REDO)**

Do not do the log roll-forward in connection with recovery.

You can `SELECT` from tables to dump them, or `DROP` or `CREATE` tables even if forced recovery is used. If you know that a given table is causing a crash on rollback, you can drop it. You can also use this to stop a runaway rollback caused by a failing mass import or `ALTER TABLE`. You can kill the `mysqld` process and set `innodb_force_recovery` to 3 to bring the database up without the rollback, then `DROP` the table that is causing the runaway rollback.

The database must not otherwise be used with any non-zero value of `innodb_force_recovery`. As a safety measure, `InnoDB` prevents users from performing `INSERT`, `UPDATE`, or `DELETE` operations when `innodb_force_recovery` is greater than 0.

13.5.8.2. Checkpoints

`InnoDB` implements a checkpoint mechanism known as “fuzzy” checkpointing. `InnoDB` flushes modified database pages from the buffer pool in small batches. There is no need to flush the buffer pool in one single batch, which would in practice stop processing of user SQL statements during the checkpointing process.

During crash recovery, `InnoDB` looks for a checkpoint label written to the log files. It knows that all modifications to the database before the label are present in the disk image of the database. Then `InnoDB` scans the log files forward from the checkpoint, applying the logged modifications to the database.

`InnoDB` writes to its log files on a rotating basis. All committed modifications that make the database pages in the buffer pool different from the images on disk must be available in the log files in case `InnoDB` has to do a recovery. This means that when `InnoDB` starts to reuse a log file, it has to make sure that the database page images on disk contain the modifications logged in the log file that `InnoDB` is going to reuse. In other words, `InnoDB` must create a checkpoint and this often involves flushing of modified database pages to disk.

The preceding description explains why making your log files very large may save disk I/O in checkpointing. It often makes sense to set the total size of the log files as big as the buffer pool or even bigger. The drawback of using large log files is that crash recovery can take longer because there is more logged information to apply to the database.

13.5.9. Moving an `InnoDB` Database to Another Machine

On Windows, `InnoDB` always stores database and table names internally in lowercase. To move databases in a binary format from

Unix to Windows or from Windows to Unix, you should have all table and database names in lowercase. A convenient way to accomplish this is to add the following line to the `[mysqld]` section of your `my.cnf` or `my.ini` file before creating any databases or tables:

```
[mysqld]
lower_case_table_names=1
```

Like **MyISAM** data files, **InnoDB** data and log files are binary-compatible on all platforms having the same floating-point number format. You can move an **InnoDB** database simply by copying all the relevant files listed in [Section 13.5.8, “Backing Up and Recovering an InnoDB Database”](#). If the floating-point formats differ but you have not used **FLOAT** or **DOUBLE** data types in your tables, then the procedure is the same: simply copy the relevant files. If the formats differ and your tables contain floating-point data, you must use **mysqldump** to dump your tables on one machine and then import the dump files on the other machine.

One way to increase performance is to switch off autocommit mode when importing data, assuming that the tablespace has enough space for the big rollback segment that the import transactions generate. Do the commit only after importing a whole table or a segment of a table.

13.5.10. InnoDB Transaction Model and Locking

In the **InnoDB** transaction model, the goal is to combine the best properties of a multi-versioning database with traditional two-phase locking. **InnoDB** does locking on the row level and runs queries as non-locking consistent reads by default, in the style of Oracle. The lock table in **InnoDB** is stored so space-efficiently that lock escalation is not needed: Typically several users are allowed to lock every row in the database, or any random subset of the rows, without **InnoDB** running out of memory.

13.5.10.1. InnoDB Lock Modes

InnoDB implements standard row-level locking where there are two types of locks:

- A shared (**S**) lock allows a transaction to read a row (tuple).
- An exclusive (**X**) lock allows a transaction to update or delete a row.

If transaction **T1** holds a shared (**S**) lock on tuple **t**, then

- A request from some distinct transaction **T2** for an **S** lock on **t** can be granted immediately. As a result, both **T1** and **T2** hold an **S** lock on **t**.
- A request from some distinct transaction **T2** for an **X** lock on **t** cannot be granted immediately.

If a transaction **T1** holds an exclusive (**X**) lock on tuple **t**, then a request from some distinct transaction **T2** for a lock of either type on **t** cannot be granted immediately. Instead, transaction **T2** has to wait for transaction **T1** to release its lock on tuple **t**.

Additionally, **InnoDB** supports *multiple granularity locking* which allows coexistence of record locks and locks on entire tables. To make locking at multiple granularity levels practical, additional types of locks called *intention locks* are used. Intention locks are table locks in **InnoDB**. The idea behind intention locks is for a transaction to indicate which type of lock (shared or exclusive) it will require later for a row in that table. There are two types of intention locks used in **InnoDB** (assume that transaction **T** has requested a lock of the indicated type on table **R**):

- Intention shared (**IS**): Transaction **T** intends to set **S** locks on individual rows in table **R**.
- Intention exclusive (**IX**): Transaction **T** intends to set **X** locks on those rows.

The intention locking protocol is as follows:

- Before a given transaction can acquire an **S** lock on a given row, it must first acquire an **IS** or stronger lock on the table containing that row.
- Before a given transaction can acquire an **X** lock on a given row, it must first acquire an **IX** lock on the table containing that row.

These rules can be conveniently summarized by means of a *lock type compatibility matrix*:

	<i>X</i>	<i>IX</i>	<i>S</i>	<i>IS</i>
<i>X</i>	Conflict	Conflict	Conflict	Conflict
<i>IX</i>	Conflict	Compatible	Conflict	Compatible
<i>S</i>	Conflict	Conflict	Compatible	Compatible
<i>IS</i>	Conflict	Compatible	Compatible	Compatible

A lock is granted to a requesting transaction if it is compatible with existing locks. A lock is not granted to a requesting transaction if it conflicts with existing locks. A transaction waits until the conflicting existing lock is released. If a lock request conflicts with an existing lock and cannot be granted because it would cause deadlock, an error occurs.

Thus, intention locks do not block anything except full table requests (for example, `LOCK TABLES ... WRITE`). The main purpose of *IX* and *IS* locks is to show that someone is locking a row, or going to lock a row in the table.

The following example illustrates how an error can occur when a lock request would cause a deadlock. The example involves two clients, A and B.

First, client A creates a table containing one row, and then begins a transaction. Within the transaction, A obtains an *S* lock on the row by selecting it in share mode:

```
mysql> CREATE TABLE t (i INT) ENGINE = InnoDB;
Query OK, 0 rows affected (1.07 sec)

mysql> INSERT INTO t (i) VALUES(1);
Query OK, 1 row affected (0.09 sec)

mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM t WHERE i = 1 LOCK IN SHARE MODE;
+-----+
| i     |
+-----+
|      1 |
+-----+
1 row in set (0.10 sec)
```

Next, client B begins a transaction and attempts to delete the row from the table:

```
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> DELETE FROM t WHERE i = 1;
```

The delete operation requires an *X* lock. The lock cannot be granted because it is incompatible with the *S* lock that client A holds, so the request goes on the queue of lock requests for the row and client B blocks.

Finally, client A also attempts to delete the row from the table:

```
mysql> DELETE FROM t WHERE i = 1;
ERROR 1213 (40001): Deadlock found when trying to get lock;
try restarting transaction
```

Deadlock occurs here because client A needs an *X* lock to delete the row. However, that lock request cannot be granted because client B already has a request for an *X* lock and is waiting for client A to release its *S* lock. Nor can the *S* lock held by A be upgraded to an *X* lock because of the prior request by B for an *X* lock. As a result, *InnoDB* generates an error for client A and releases its locks. At that point, the lock request for client B can be granted and B deletes the row from the table.

13.5.10.2. *InnoDB* and AUTOCOMMIT

In *InnoDB*, all user activity occurs inside a transaction. If the autocommit mode is enabled, each SQL statement forms a single transaction on its own. By default, MySQL starts new connections with autocommit enabled.

If the autocommit mode is switched off with `SET AUTOCOMMIT = 0`, then we can consider that a user always has a transaction open. An SQL `COMMIT` or `ROLLBACK` statement ends the current transaction and a new one starts. A `COMMIT` means that the changes made

in the current transaction are made permanent and become visible to other users. A **ROLLBACK** statement, on the other hand, cancels all modifications made by the current transaction. Both statements release all **InnoDB** locks that were set during the current transaction.

If the connection has autocommit enabled, the user can still perform a multiple-statement transaction by starting it with an explicit **START TRANSACTION** or **BEGIN** statement and ending it with **COMMIT** or **ROLLBACK**.

13.5.10.3. InnoDB and TRANSACTION ISOLATION LEVEL

In terms of the SQL:1992 transaction isolation levels, the **InnoDB** default is **REPEATABLE READ**. **InnoDB** offers all four transaction isolation levels described by the SQL standard. You can set the default isolation level for all connections by using the **-transaction-isolation** option on the command line or in an option file. For example, you can set the option in the **[mysqld]** section of an option file like this:

```
[mysqld]
transaction-isolation = {READ-UNCOMMITTED | READ-COMMITTED
                        | REPEATABLE-READ | SERIALIZABLE}
```

A user can change the isolation level for a single session or for all new incoming connections with the **SET TRANSACTION** statement. Its syntax is as follows:

```
SET [SESSION | GLOBAL] TRANSACTION ISOLATION LEVEL
   {READ UNCOMMITTED | READ COMMITTED
    | REPEATABLE READ | SERIALIZABLE}
```

Note that there are hyphens in the level names for the **--transaction-isolation** option, but not for the **SET TRANSACTION** statement.

The default behavior is to set the isolation level for the next (not started) transaction. If you use the **GLOBAL** keyword, the statement sets the default transaction level globally for all new connections created from that point on (but not for existing connections). You need the **SUPER** privilege to do this. Using the **SESSION** keyword sets the default transaction level for all future transactions performed on the current connection.

Any client is free to change the session isolation level (even in the middle of a transaction), or the isolation level for the next transaction.

You can determine the global and session transaction isolation levels by checking the value of the **tx_isolation** system variable with these statements:

```
SELECT @@global.tx_isolation;
SELECT @@tx_isolation;
```

In row-level locking, **InnoDB** uses next-key locking. That means that besides index records, **InnoDB** can also lock the “gap” preceding an index record to block insertions by other users immediately before the index record. A next-key lock refers to a lock that locks an index record and the gap before it. A gap lock refers to a lock that only locks a gap before some index record. Next-key locking for searches or index scans can be disabled by enabling the **innodb_locks_unsafe_for_binlog** system variable.

A detailed description of each isolation level in **InnoDB** follows:

- **READ UNCOMMITTED**

SELECT statements are performed in a non-locking fashion, but a possible earlier version of a record might be used. Thus, using this isolation level, such reads are not consistent. This is also called a “dirty read.” Otherwise, this isolation level works like **READ COMMITTED**.

- **READ COMMITTED**

A somewhat Oracle-like isolation level. All **SELECT ... FOR UPDATE** and **SELECT ... LOCK IN SHARE MODE** statements lock only the index records, not the gaps before them, and thus allow the free insertion of new records next to locked records. **UPDATE** and **DELETE** statements using a unique index with a unique search condition lock only the index record found, not the gap before it. In range-type **UPDATE** and **DELETE** statements, **InnoDB** must set next-key or gap locks and block insertions by other users to the gaps covered by the range. This is necessary because “phantom rows” must be blocked for MySQL replication and recovery to work.

Consistent reads behave as in Oracle: Each consistent read, even within the same transaction, sets and reads its own fresh snapshot. See [Section 13.5.10.4, “Consistent Non-Locking Read”](#).

- **REPEATABLE READ**

This is the default isolation level of **InnoDB**. **SELECT ... FOR UPDATE**, **SELECT ... LOCK IN SHARE MODE**, **UPDATE**, and **DELETE** statements that use a unique index with a unique search condition lock only the index record found, not the gap before it. With other search conditions, these operations employ next-key locking, locking the index range scanned with next-key or gap locks, and block new insertions by other users.

In consistent reads, there is an important difference from the **READ COMMITTED** isolation level: All consistent reads within the same transaction read the same snapshot established by the first read. This convention means that if you issue several plain **SELECT** statements within the same transaction, these **SELECT** statements are consistent also with respect to each other. See [Section 13.5.10.4, “Consistent Non-Locking Read”](#).

- **SERIALIZABLE**

This level is like **REPEATABLE READ**, but **InnoDB** implicitly commits all plain **SELECT** statements to **SELECT ... LOCK IN SHARE MODE**.

In MySQL 5.1, if the **READ COMMITTED** isolation level is used or the **innodb_locks_unsafe_for_binlog** system variable is enabled, there is no **InnoDB** gap locking except in constraint checking. Also, record locks for non-matching rows are released after MySQL has evaluated the **WHERE** condition.

13.5.10.4. Consistent Non-Locking Read

A consistent read means that **InnoDB** uses multi-versioning to present to a query a snapshot of the database at a point in time. The query sees the changes made by those transactions that committed before that point of time, and no changes made by later or uncommitted transactions. The exception to this rule is that the query sees the changes made by earlier statements within the same transaction. Note that the exception to the rule causes the following anomaly: if you update some rows in a table, a **SELECT** will see the latest version of the updated rows, but it might also see older versions of any rows. If other users simultaneously update the same table, the anomaly means that you may see the table in a state that never existed in the database.

If you are running with the default **REPEATABLE READ** isolation level, all consistent reads within the same transaction read the snapshot established by the first such read in that transaction. You can get a fresher snapshot for your queries by committing the current transaction and after that issuing new queries.

Consistent read is the default mode in which **InnoDB** processes **SELECT** statements in **READ COMMITTED** and **REPEATABLE READ** isolation levels. A consistent read does not set any locks on the tables it accesses, and therefore other users are free to modify those tables at the same time a consistent read is being performed on the table.

Note that consistent read does not work over **DROP TABLE** and over **ALTER TABLE**. Consistent read does not work over **DROP TABLE** because MySQL can't use a table that has been dropped and **InnoDB** destroys the table. Consistent read does not work over **ALTER TABLE** because **ALTER TABLE** works by making a temporary copy of the original table and deleting the original table when the temporary copy is built. When you reissue a consistent read within a transaction, rows in the new table are not visible because those rows did not exist when the transaction's snapshot was taken.

InnoDB uses a consistent read for select in clauses like **INSERT INTO ... SELECT** and **UPDATE ... (SELECT)** that do not specify **FOR UPDATE** or **IN SHARE MODE** if the **innodb_locks_unsafe_for_binlog** option is set and the isolation level of the transaction is not set to serializable. Thus no locks are set to rows read from selected table. Otherwise, **InnoDB** uses stronger locks and the **SELECT** part acts like **READ COMMITTED**, where each consistent read, even within the same transaction, sets and reads its own fresh snapshot.

13.5.10.5. **SELECT ... FOR UPDATE** and **SELECT ... LOCK IN SHARE MODE** Locking Reads

In some circumstances, a consistent read is not convenient. For example, you might want to add a new row into your table **child**, and make sure that the child has a parent in table **parent**. The following example shows how to implement referential integrity in your application code.

Suppose that you use a consistent read to read the table **parent** and indeed see the parent of the child in the table. Can you safely add the child row to table **child**? No, because it may happen that meanwhile some other user deletes the parent row from the table **parent** without you being aware of it.

The solution is to perform the **SELECT** in a locking mode using **LOCK IN SHARE MODE**:

```
SELECT * FROM parent WHERE NAME = 'Jones' LOCK IN SHARE MODE;
```

Performing a read in share mode means that we read the latest available data, and set a shared mode lock on the rows we read. A shared mode lock prevents others from updating or deleting the row we have read. Also, if the latest data belongs to a yet uncommitted transaction of another client connection, we wait until that transaction commits. After we see that the preceding query returns the parent 'Jones', we can safely add the child record to the `child` table and commit our transaction.

Let us look at another example: We have an integer counter field in a table `child_codes` that we use to assign a unique identifier to each child added to table `child`. Obviously, using a consistent read or a shared mode read to read the present value of the counter is not a good idea because two users of the database may then see the same value for the counter, and a duplicate-key error occurs if two users attempt to add children with the same identifier to the table.

Here, `LOCK IN SHARE MODE` is not a good solution because if two users read the counter at the same time, at least one of them ends up in deadlock when attempting to update the counter.

In this case, there are two good ways to implement the reading and incrementing of the counter: (1) update the counter first by incrementing it by 1 and only after that read it, or (2) read the counter first with a lock mode `FOR UPDATE`, and increment after that. The latter approach can be implemented as follows:

```
SELECT counter_field FROM child_codes FOR UPDATE;
UPDATE child_codes SET counter_field = counter_field + 1;
```

A `SELECT ... FOR UPDATE` reads the latest available data, setting exclusive locks on each row it reads. Thus, it sets the same locks a searched SQL `UPDATE` would set on the rows.

The preceding description is merely an example of how `SELECT ... FOR UPDATE` works. In MySQL, the specific task of generating a unique identifier actually can be accomplished using only a single access to the table:

```
UPDATE child_codes SET counter_field = LAST_INSERT_ID(counter_field + 1);
SELECT LAST_INSERT_ID();
```

The `SELECT` statement merely retrieves the identifier information (specific to the current connection). It does not access any table.

Locks set by `IN SHARE MODE` and `FOR UPDATE` reads are released when the transaction is committed or rolled back.

Note

Locking of rows for update using `SELECT FOR UPDATE` only applies when `AUTOCOMMIT` is switched off. If `AUTO-COMMIT` is on, then the rows matching the specification are not locked.

13.5.10.6. Next-Key Locking: Avoiding the Phantom Problem

In row-level locking, `InnoDB` uses an algorithm called *next-key locking*. `InnoDB` performs the row-level locking in such a way that when it searches or scans an index of a table, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index record locks.

The next-key locks that `InnoDB` sets on index records also affect the “gap” before that index record. If a user has a shared or exclusive lock on record `R` in an index, another user cannot insert a new index record immediately before `R` in the index order. (A gap lock refers to a lock that only locks a gap before some index record.)

This next-key locking of gaps is done to prevent the so-called “phantom problem.” Suppose that you want to read and lock all children from the `child` table having an identifier value greater than 100, with the intention of updating some column in the selected rows later:

```
SELECT * FROM child WHERE id > 100 FOR UPDATE;
```

Suppose that there is an index on the `id` column. The query scans that index starting from the first record where `id` is bigger than 100. If the locks set on the index records would not lock out inserts made in the gaps, a new row might meanwhile be inserted to the table. If you execute the same `SELECT` within the same transaction, you would see a new row in the result set returned by the query. This is contrary to the isolation principle of transactions: A transaction should be able to run so that the data it has read does not change during the transaction. If we regard a set of rows as a data item, the new “phantom” child would violate this isolation principle.

When `InnoDB` scans an index, it can also lock the gap after the last record in the index. Just that happens in the previous example: The locks set by `InnoDB` prevent any insert to the table where `id` would be bigger than 100.

You can use next-key locking to implement a uniqueness check in your application: If you read your data in share mode and do not see a duplicate for a row you are going to insert, then you can safely insert your row and know that the next-key lock set on the successor of

your row during the read prevents anyone meanwhile inserting a duplicate for your row. Thus, the next-key locking allows you to “lock” the non-existence of something in your table.

In MySQL 5.1, if the `READ COMMITTED` isolation level is used or the `innodb_locks_unsafe_for_binlog` system variable is enabled, there is no **InnoDB** gap locking except in constraint checking. Also, record locks for non-matching rows are released after MySQL has evaluated the `WHERE` condition.

13.5.10.7. An Example of Consistent Read in InnoDB

Suppose that you are running in the default `REPEATABLE READ` isolation level. When you issue a consistent read (that is, an ordinary `SELECT` statement), **InnoDB** gives your transaction a timepoint according to which your query sees the database. If another transaction deletes a row and commits after your timepoint was assigned, you do not see the row as having been deleted. Inserts and updates are treated similarly.

You can advance your timepoint by committing your transaction and then doing another `SELECT`.

This is called *multi-versioned concurrency control*.

	User A	User B
time	SET AUTOCOMMIT=0;	SET AUTOCOMMIT=0;
	SELECT * FROM t;	
	empty set	INSERT INTO t VALUES (1, 2);
v	SELECT * FROM t;	
	empty set	COMMIT;
	SELECT * FROM t;	
	empty set	
	COMMIT;	
	SELECT * FROM t;	

	1 2	

	1 row in set	

In this example, user A sees the row inserted by B only when B has committed the insert and A has committed as well, so that the timepoint is advanced past the commit of B.

If you want to see the “freshest” state of the database, you should use either the `READ COMMITTED` isolation level or a locking read:

```
SELECT * FROM t LOCK IN SHARE MODE;
```

13.5.10.8. Locks Set by Different SQL Statements in InnoDB

A locking read, an `UPDATE`, or a `DELETE` generally set record locks on every index record that is scanned in the processing of the SQL statement. It does not matter if there are `WHERE` conditions in the statement that would exclude the row. **InnoDB** does not remember the exact `WHERE` condition, but only knows which index ranges were scanned. The record locks are normally next-key locks that also block inserts to the “gap” immediately before the record.

If the locks to be set are exclusive, **InnoDB** always retrieves also the clustered index record and sets a lock on it.

If you do not have indexes suitable for your statement and MySQL has to scan the whole table to process the statement, every row of the table becomes locked, which in turn blocks all inserts by other users to the table. It is important to create good indexes so that your queries do not unnecessarily need to scan many rows.

InnoDB sets specific types of locks as follows:

- `SELECT ... FROM` is a consistent read, reading a snapshot of the database and setting no locks unless the transaction isolation level is set to `SERIALIZABLE`. For `SERIALIZABLE` level, this sets shared next-key locks on the index records it encounters.
- `SELECT ... FROM ... LOCK IN SHARE MODE` sets shared next-key locks on all index records the read encounters.
- `SELECT ... FROM ... FOR UPDATE` sets exclusive next-key locks on all index records the read encounters and also on the

corresponding clustered index records if a secondary index is used in the search.

- **INSERT INTO ... VALUES (...)** sets an exclusive lock on the inserted row. Note that this lock is not a next-key lock and does not prevent other users from inserting to the gap before the inserted row. If a duplicate-key error occurs, a shared lock on the duplicate index record is set.
- While initializing a previously specified **AUTO_INCREMENT** column on a table, **InnoDB** sets an exclusive lock on the end of the index associated with the **AUTO_INCREMENT** column. In accessing the auto-increment counter, **InnoDB** uses a specific table lock mode **AUTO-INC** where the lock lasts only to the end of the current SQL statement, not to the end of the entire transaction. Note that other clients cannot insert into the table while the **AUTO-INC** table lock is held; see [Section 13.5.10.2, “InnoDB and AUTO-COMMIT”](#).

InnoDB fetches the value of a previously initialized **AUTO_INCREMENT** column without setting any locks.

- **INSERT INTO T SELECT ... FROM S WHERE ...** sets an exclusive (non-next-key) lock on each row inserted into **T**. **InnoDB** sets shared next-key locks on **S**, unless **innodb_locks_unsafe_for_binlog** is enabled, in which case it does the search on **S** as a consistent read. **InnoDB** has to set locks in the latter case: In roll-forward recovery from a backup, every SQL statement has to be executed in exactly the same way it was done originally.
- **CREATE TABLE ... SELECT ...** performs the **SELECT** as a consistent read or with shared locks, as in the previous item.
- **REPLACE** is done like an insert if there is no collision on a unique key. Otherwise, an exclusive next-key lock is placed on the row that has to be updated.
- **UPDATE ... WHERE ...** sets an exclusive next-key lock on every record the search encounters.
- **DELETE FROM ... WHERE ...** sets an exclusive next-key lock on every record the search encounters.
- If a **FOREIGN KEY** constraint is defined on a table, any insert, update, or delete that requires the constraint condition to be checked sets shared record-level locks on the records that it looks at to check the constraint. **InnoDB** also sets these locks in the case where the constraint fails.
- **LOCK TABLES** sets table locks, but it is the higher MySQL layer above the **InnoDB** layer that sets these locks. **InnoDB** is aware of table locks if **innodb_table_locks=1** (the default) and **AUTOCOMMIT=0**, and the MySQL layer above **InnoDB** knows about row-level locks. Otherwise, **InnoDB**'s automatic deadlock detection cannot detect deadlocks where such table locks are involved. Also, because the higher MySQL layer does not know about row-level locks, it is possible to get a table lock on a table where another user currently has row-level locks. However, this does not endanger transaction integrity, as discussed in [Section 13.5.10.10, “Deadlock Detection and Rollback”](#). See also [Section 13.5.16, “Restrictions on InnoDB Tables”](#).
- In MySQL 5.1, if the **READ COMMITTED** isolation level is used or the **innodb_locks_unsafe_for_binlog** system variable is enabled, there is no **InnoDB** gap locking except in constraint checking. Also, record locks for non-matching rows are released after MySQL has evaluated the **WHERE** condition.

13.5.10.9. Implicit Transaction Commit and Rollback

By default, MySQL begins each client connection with autocommit mode enabled. When autocommit is enabled, MySQL does a commit after each SQL statement if that statement did not return an error. If an SQL statement returns an error, the commit or rollback behavior depends on the error. See [Section 13.5.15, “InnoDB Error Handling”](#).

If you have the autocommit mode off and close a connection without explicitly committing the final transaction, MySQL rolls back that transaction.

Each of the following statements (and any synonyms for them) implicitly end a transaction, as if you had done a **COMMIT** before executing the statement:

- **ALTER EVENT, ALTER FUNCTION, ALTER FUNCTION, ALTER PROCEDURE, ALTER TABLE, BEGIN, CREATE DATABASE, CREATE EVENT, CREATE FUNCTION, CREATE INDEX, CREATE PROCEDURE, CREATE TABLE, DROP DATABASE, DROP EVENT, DROP FUNCTION, DROP INDEX, DROP PROCEDURE, DROP TABLE, LOAD DATA INFILE LOCK TABLES, RENAME TABLE, SET AUTOCOMMIT=1, START TRANSACTION, TRUNCATE TABLE, UNLOCK TABLES.**
- Beginning with MySQL 5.1.3, the **ALTER VIEW, CREATE TRIGGER, CREATE USER, CREATE VIEW, DROP TRIGGER, DROP USER, DROP VIEW, and RENAME USER** statements cause an implicit commit.

- **UNLOCK TABLES** commits a transaction only if any tables currently have been locked with **LOCK TABLES**. This does not occur for **UNLOCK TABLES** following **FLUSH TABLES WITH READ LOCK** because the latter statement does not acquire table-level locks.
- The **CREATE TABLE** statement in **InnoDB** is processed as a single transaction. This means that a **ROLLBACK** from the user does not undo **CREATE TABLE** statements the user made during that transaction.
- **CREATE TABLE** and **DROP TABLE** do not commit a transaction if the **TEMPORARY** keyword is used. (This does not apply to other operations on temporary tables such as **CREATE INDEX**, which do cause a commit.)
- In MySQL 5.1.11 and earlier, **LOAD DATA INFILE** caused an implicit commit for all storage engines. Beginning with MySQL 5.1.12, it causes an implicit commit only for tables using the **NDB** storage engine. For more information, see [Bug#11151](#).

Transactions cannot be nested. This is a consequence of the implicit **COMMIT** performed for any current transaction when you issue a **START TRANSACTION** statement or one of its synonyms.

Statements that cause implicit commit cannot be used in an XA transaction while the transaction is in an **ACTIVE** state.

The **BEGIN** statement differs from the use of the **BEGIN** keyword that starts a **BEGIN ... END** compound statement. The latter does not cause an implicit commit. See [Section 19.2.5, “BEGIN ... END Compound Statement Syntax”](#).

13.5.10.10. Deadlock Detection and Rollback

InnoDB automatically detects a deadlock of transactions and rolls back a transaction or transactions to break the deadlock. **InnoDB** tries to pick small transactions to roll back, where the size of a transaction is determined by the number of rows inserted, updated, or deleted.

InnoDB is aware of table locks if **innodb_table_locks=1** (the default) and **AUTOCOMMIT=0**, and the MySQL layer above it knows about row-level locks. Otherwise, **InnoDB** cannot detect deadlocks where a table lock set by a MySQL **LOCK TABLES** statement or a lock set by a storage engine other than **InnoDB** is involved. You must resolve these situations by setting the value of the **innodb_lock_wait_timeout** system variable.

When **InnoDB** performs a complete rollback of a transaction, all locks set by the transaction are released. However, if just a single SQL statement is rolled back as a result of an error, some of the locks set by the statement may be preserved. This happens because **InnoDB** stores row locks in a format such that it cannot know afterward which lock was set by which statement.

13.5.10.11. How to Cope with Deadlocks

Deadlocks are a classic problem in transactional databases, but they are not dangerous unless they are so frequent that you cannot run certain transactions at all. Normally, you must write your applications so that they are always prepared to re-issue a transaction if it gets rolled back because of a deadlock.

InnoDB uses automatic row-level locking. You can get deadlocks even in the case of transactions that just insert or delete a single row. That is because these operations are not really “atomic”; they automatically set locks on the (possibly several) index records of the row inserted or deleted.

You can cope with deadlocks and reduce the likelihood of their occurrence with the following techniques:

- Use **SHOW ENGINE INNODB STATUS** to determine the cause of the latest deadlock. That can help you to tune your application to avoid deadlocks.
- Always be prepared to re-issue a transaction if it fails due to deadlock. Deadlocks are not dangerous. Just try again.
- Commit your transactions often. Small transactions are less prone to collision.
- If you are using locking reads (**SELECT ... FOR UPDATE** or **... LOCK IN SHARE MODE**), try using a lower isolation level such as **READ COMMITTED**.
- Access your tables and rows in a fixed order. Then transactions form well-defined queues and do not deadlock.
- Add well-chosen indexes to your tables. Then your queries need to scan fewer index records and consequently set fewer locks. Use **EXPLAIN SELECT** to determine which indexes the MySQL server regards as the most appropriate for your queries.

- Use less locking. If you can afford to allow a `SELECT` to return data from an old snapshot, do not add the clause `FOR UPDATE` or `LOCK IN SHARE MODE` to it. Using the `READ COMMITTED` isolation level is good here, because each consistent read within the same transaction reads from its own fresh snapshot.
- If nothing else helps, serialize your transactions with table-level locks. The correct way to use `LOCK TABLES` with transactional tables, such as `InnoDB` tables, is to set `AUTOCOMMIT = 0` and not to call `UNLOCK TABLES` until after you commit the transaction explicitly. For example, if you need to write to table `t1` and read from table `t2`, you can do this:

```
SET AUTOCOMMIT=0;
LOCK TABLES t1 WRITE, t2 READ, ...;
... do something with tables t1 and t2 here ...
COMMIT;
UNLOCK TABLES;
```

Table-level locks make your transactions queue nicely, and deadlocks are avoided.

- Another way to serialize transactions is to create an auxiliary “semaphore” table that contains just a single row. Have each transaction update that row before accessing other tables. In that way, all transactions happen in a serial fashion. Note that the `InnoDB` instant deadlock detection algorithm also works in this case, because the serializing lock is a row-level lock. With MySQL table-level locks, the timeout method must be used to resolve deadlocks.

13.5.11. InnoDB Performance Tuning Tips

- In `InnoDB`, having a long `PRIMARY KEY` wastes a lot of disk space because its value must be stored with every secondary index record. (See [Section 13.5.13, “InnoDB Table and Index Structures”](#).) Create an `AUTO_INCREMENT` column as the primary key if your primary key is long.
- If the Unix `top` tool or the Windows Task Manager shows that the CPU usage percentage with your workload is less than 70%, your workload is probably disk-bound. Maybe you are making too many transaction commits, or the buffer pool is too small. Making the buffer pool bigger can help, but do not set it equal to more than 80% of physical memory.
- Wrap several modifications into one transaction. `InnoDB` must flush the log to disk at each transaction commit if that transaction made modifications to the database. The rotation speed of a disk is typically at most 167 revolutions/second, which constrains the number of commits to the same 167th of a second if the disk does not “fool” the operating system.
- If you can afford the loss of some of the latest committed transactions if a crash occurs, you can set the `innodb_flush_log_at_trx_commit` parameter to 0. `InnoDB` tries to flush the log once per second anyway, although the flush is not guaranteed. You should also set the value of `innodb_support_xa` to 0 which will reduce the number of disk flushes due to synchronizing on disk data and the binary log.
- Make your log files big, even as big as the buffer pool. When `InnoDB` has written the log files full, it has to write the modified contents of the buffer pool to disk in a checkpoint. Small log files cause many unnecessary disk writes. The drawback of big log files is that the recovery time is longer.
- Make the log buffer quite large as well (on the order of 8MB).
- Use the `VARCHAR` data type instead of `CHAR` if you are storing variable-length strings or if the column may contain many `NULL` values. A `CHAR(N)` column always takes `N` characters to store data, even if the string is shorter or its value is `NULL`. Smaller tables fit better in the buffer pool and reduce disk I/O.

When using `row_format=compact` (the default `InnoDB` record format in MySQL 5.1) and variable-length character sets, such as `utf8` or `sjis`, `CHAR(N)` will occupy a variable amount of space, at least `N` bytes.

- In some versions of GNU/Linux and Unix, flushing files to disk with the Unix `fsync()` call (which `InnoDB` uses by default) and other similar methods is surprisingly slow. If you are dissatisfied with database write performance, you might try setting the `innodb_flush_method` parameter to `O_DSYNC`. Although `O_DSYNC` seems to be slower on most systems, yours might not be one of them.
- When using the `InnoDB` storage engine on Solaris 10 for x86_64 architecture (AMD Opteron), it is important to mount any filesystems used for storing `InnoDB`-related files using the `forcedirectio` option. (The default on Solaris 10/x86_64 is *not* to use this option.) Failure to use `forcedirectio` causes a serious degradation of `InnoDB`'s speed and performance on this platform.

When using the `InnoDB` storage engine with a large `innodb_buffer_pool_size` value on any release of Solaris 2.6 and up and any platform (sparc/x86/x64/amd64), a significant performance gain can be achieved by placing `InnoDB` data files and log files

on raw devices or on a separate direct I/O UFS filesystem (using mount option `forcedirectio`; see `mount_ufs(1M)`). Users of the Veritas filesystem VxFS should use the mount option `convosync=direct`.

Other MySQL data files, such as those for **MyISAM** tables, should not be placed on a direct I/O filesystem. Executables or libraries *must not* be placed on a direct I/O filesystem.

- When importing data into **InnoDB**, make sure that MySQL does not have autocommit mode enabled because that requires a log flush to disk for every insert. To disable autocommit during your import operation, surround it with `SET AUTOCOMMIT` and `COMMIT` statements:

```
SET AUTOCOMMIT=0;
... SQL import statements ...
COMMIT;
```

If you use the `mysqldump` option `--opt`, you get dump files that are fast to import into an **InnoDB** table, even without wrapping them with the `SET AUTOCOMMIT` and `COMMIT` statements.

- Beware of big rollbacks of mass inserts: **InnoDB** uses the insert buffer to save disk I/O in inserts, but no such mechanism is used in a corresponding rollback. A disk-bound rollback can take 30 times as long to perform as the corresponding insert. Killing the database process does not help because the rollback starts again on server startup. The only way to get rid of a runaway rollback is to increase the buffer pool so that the rollback becomes CPU-bound and runs fast, or to use a special procedure. See [Section 13.5.8.1, “Forcing InnoDB Recovery”](#).
- Beware also of other big disk-bound operations. Use `DROP TABLE` and `CREATE TABLE` to empty a table, not `DELETE FROM tbl_name`.
- Use the multiple-row `INSERT` syntax to reduce communication overhead between the client and the server if you need to insert many rows:

```
INSERT INTO yourtable VALUES (1,2), (5,5), ...;
```

This tip is valid for inserts into any table, not just **InnoDB** tables.

- If you have **UNIQUE** constraints on secondary keys, you can speed up table imports by temporarily turning off the uniqueness checks during the import session:

```
SET UNIQUE_CHECKS=0;
... import operation ...
SET UNIQUE_CHECKS=1;
```

For big tables, this saves a lot of disk I/O because **InnoDB** can use its insert buffer to write secondary index records in a batch. Be certain that the data contains no duplicate keys. `UNIQUE_CHECKS` allows but does not require storage engines to ignore duplicate keys.

- If you have **FOREIGN KEY** constraints in your tables, you can speed up table imports by turning the foreign key checks off for the duration of the import session:

```
SET FOREIGN_KEY_CHECKS=0;
... import operation ...
SET FOREIGN_KEY_CHECKS=1;
```

For big tables, this can save a lot of disk I/O.

- If you often have recurring queries for tables that are not updated frequently, use the query cache:

```
[mysqld]
query_cache_type = ON
query_cache_size = 10M
```

- Unlike **MyISAM**, **InnoDB** does not store an index cardinality value in its tables. Instead, **InnoDB** computes a cardinality for a table the first time it accesses it after startup. With a large number of tables, this might take significant time. It is the initial table open operation that is important, so to “warm up” a table for later use, you might want to use it immediately after start up by issuing a statement such as `SELECT 1 FROM tbl_name LIMIT 1`.

For optimization recommendations geared to your specific circumstances subscribe to the MySQL Enterprise Monitor. For more information see <http://www.mysql.com/products/enterprise/advisors.html>.

13.5.11.1. SHOW ENGINE INNODB STATUS and the InnoDB Monitors

InnoDB includes InnoDB Monitors that print information about the InnoDB internal state. You can use the `SHOW ENGINE INNODB STATUS` SQL statement at any time to fetch the output of the standard InnoDB Monitor to your SQL client. This information is useful in performance tuning. (If you are using the `mysql` interactive SQL client, the output is more readable if you replace the usual semicolon statement terminator with `\G`.) For a discussion of InnoDB lock modes, see [Section 13.5.10.1, “InnoDB Lock Modes”](#).

```
mysql> SHOW ENGINE INNODB STATUS\G
```

Another way to use InnoDB Monitors is to let them periodically write data to the standard output of the `mysqld` server. In this case, no output is sent to clients. When switched on, InnoDB Monitors print data about every 15 seconds. Server output usually is directed to the `.err` log in the MySQL data directory. This data is useful in performance tuning. On Windows, you must start the server from a command prompt in a console window with the `--console` option if you want to direct the output to the window rather than to the error log.

Monitor output includes the following types of information:

- Table and record locks held by each active transaction
- Lock waits of a transactions
- Semaphore waits of threads
- Pending file I/O requests
- Buffer pool statistics
- Purge and insert buffer merge activity of the main InnoDB thread

To cause the standard InnoDB Monitor to write to the standard output of `mysqld`, use the following SQL statement:

```
CREATE TABLE innodb_monitor (a INT) ENGINE=INNODB;
```

The monitor can be stopped by issuing the following statement:

```
DROP TABLE innodb_monitor;
```

The `CREATE TABLE` syntax is just a way to pass a command to the InnoDB engine through MySQL's SQL parser: The only things that matter are the table name `innodb_monitor` and that it be an InnoDB table. The structure of the table is not relevant at all for the InnoDB Monitor. If you shut down the server, the monitor does not restart automatically when you restart the server. You must drop the monitor table and issue a new `CREATE TABLE` statement to start the monitor. (This syntax may change in a future release.)

You can use `innodb_lock_monitor` in a similar fashion. This is the same as `innodb_monitor`, except that it also provides a great deal of lock information. A separate `innodb_tablespace_monitor` prints a list of created file segments existing in the tablespace and validates the tablespace allocation data structures. In addition, there is `innodb_table_monitor` with which you can print the contents of the InnoDB internal data dictionary.

A sample of InnoDB Monitor output:

```
mysql> SHOW ENGINE INNODB STATUS\G
***** 1. row *****
Status:

END OF INNODB MONITOR OUTPUT
=====

```

Some notes on the output:

- If the **TRANSACTIONS** section reports lock waits, your applications may have lock contention. The output can also help to trace the reasons for transaction deadlocks.
- The **SEMAPHORES** section reports threads waiting for a semaphore and statistics on how many times threads have needed a spin or a wait on a mutex or a rw-lock semaphore. A large number of threads waiting for semaphores may be a result of disk I/O, or contention problems inside **InnoDB**. Contention can be due to heavy parallelism of queries or problems in operating system thread scheduling. Setting **innodb_thread_concurrency** smaller than the default value can help in such situations.

- The **BUFFER POOL AND MEMORY** section gives you statistics on pages read and written. You can calculate from these numbers how many data file I/O operations your queries currently are doing.
- The **ROW OPERATIONS** section shows what the main thread is doing.

InnoDB sends diagnostic output to `stderr` or to files rather than to `stdout` or fixed-size memory buffers, to avoid potential buffer overflows. As a side effect, the output of **SHOW ENGINE INNODB STATUS** is written to a status file in the MySQL data directory every fifteen seconds. The name of the file is `innodb_status.pid`, where `pid` is the server process ID. **InnoDB** removes the file for a normal shutdown. If abnormal shutdowns have occurred, instances of these status files may be present and must be removed manually. Before removing them, you might want to examine them to see whether they contain useful information about the cause of abnormal shutdowns. The `innodb_status.pid` file is created only if the configuration option `innodb_status_file=1` is set.

13.5.12. Implementation of Multi-Versioning

Because **InnoDB** is a multi-versioned storage engine, it must keep information about old versions of rows in the tablespace. This information is stored in a data structure called a *rollback segment* (after an analogous data structure in Oracle).

Internally, **InnoDB** adds two fields to each row stored in the database. A 6-byte field indicates the transaction identifier for the last transaction that inserted or updated the row. Also, a deletion is treated internally as an update where a special bit in the row is set to mark it as deleted. Each row also contains a 7-byte field called the roll pointer. The roll pointer points to an undo log record written to the rollback segment. If the row was updated, the undo log record contains the information necessary to rebuild the content of the row before it was updated.

InnoDB uses the information in the rollback segment to perform the undo operations needed in a transaction rollback. It also uses the information to build earlier versions of a row for a consistent read.

Undo logs in the rollback segment are divided into insert and update undo logs. Insert undo logs are needed only in transaction rollback and can be discarded as soon as the transaction commits. Update undo logs are used also in consistent reads, but they can be discarded only after there is no transaction present for which **InnoDB** has assigned a snapshot that in a consistent read could need the information in the update undo log to build an earlier version of a database row.

You must remember to commit your transactions regularly, including those transactions that issue only consistent reads. Otherwise, **InnoDB** cannot discard data from the update undo logs, and the rollback segment may grow too big, filling up your tablespace.

The physical size of an undo log record in the rollback segment is typically smaller than the corresponding inserted or updated row. You can use this information to calculate the space need for your rollback segment.

In the **InnoDB** multi-versioning scheme, a row is not physically removed from the database immediately when you delete it with an SQL statement. Only when **InnoDB** can discard the update undo log record written for the deletion can it also physically remove the corresponding row and its index records from the database. This removal operation is called a purge, and it is quite fast, usually taking the same order of time as the SQL statement that did the deletion.

In a scenario where the user inserts and deletes rows in smallish batches at about the same rate in the table, it is possible that the purge thread starts to lag behind, and the table grows bigger and bigger, making everything disk-bound and very slow. Even if the table carries just 10MB of useful data, it may grow to occupy 10GB with all the “dead” rows. In such a case, it would be good to throttle new row operations, and allocate more resources to the purge thread. The `innodb_max_purge_lag` system variable exists for exactly this purpose. See [Section 13.5.4, “InnoDB Startup Options and System Variables”](#), for more information.

13.5.13. InnoDB Table and Index Structures

MySQL stores its data dictionary information for tables in `.frm` files in database directories. This is true for all MySQL storage engines. But every **InnoDB** table also has its own entry in the **InnoDB** internal data dictionary inside the tablespace. When MySQL drops a table or a database, it has to delete both an `.frm` file or files, and the corresponding entries inside the **InnoDB** data dictionary. This is the reason why you cannot move **InnoDB** tables between databases simply by moving the `.frm` files.

Every **InnoDB** table has a special index called the *clustered index* where the data for the rows is stored. If you define a **PRIMARY KEY** on your table, the index of the primary key is the clustered index.

If you do not define a **PRIMARY KEY** for your table, MySQL picks the first **UNIQUE** index that has only **NOT NULL** columns as the primary key and **InnoDB** uses it as the clustered index. If there is no such index in the table, **InnoDB** internally generates a clustered index where the rows are ordered by the row ID that **InnoDB** assigns to the rows in such a table. The row ID is a 6-byte field that increases monotonically as new rows are inserted. Thus, the rows ordered by the row ID are physically in insertion order.

Accessing a row through the clustered index is fast because the row data is on the same page where the index search leads. If a table is large, the clustered index architecture often saves a disk I/O when compared to the traditional solution. (In many database systems, data storage uses a different page from the index record.)

In **InnoDB**, the records in non-clustered indexes (also called secondary indexes) contain the primary key value for the row. **InnoDB** uses this primary key value to search for the row from the clustered index. Note that if the primary key is long, the secondary indexes use more space.

InnoDB compares **CHAR** and **VARCHAR** strings of different lengths such that the remaining length in the shorter string is treated as if padded with spaces.

13.5.13.1. Physical Structure of an Index

All **InnoDB** indexes are B-trees where the index records are stored in the leaf pages of the tree. The default size of an index page is 16KB. When new records are inserted, **InnoDB** tries to leave 1/16 of the page free for future insertions and updates of the index records.

If index records are inserted in a sequential order (ascending or descending), the resulting index pages are about 15/16 full. If records are inserted in a random order, the pages are from 1/2 to 15/16 full. If the fill factor of an index page drops below 1/2, **InnoDB** tries to contract the index tree to free the page.

13.5.13.2. Insert Buffering

It is a common situation in database applications that the primary key is a unique identifier and new rows are inserted in the ascending order of the primary key. Thus, the insertions to the clustered index do not require random reads from a disk.

On the other hand, secondary indexes are usually non-unique, and insertions into secondary indexes happen in a relatively random order. This would cause a lot of random disk I/O operations without a special mechanism used in **InnoDB**.

If an index record should be inserted to a non-unique secondary index, **InnoDB** checks whether the secondary index page is in the buffer pool. If that is the case, **InnoDB** does the insertion directly to the index page. If the index page is not found in the buffer pool, **InnoDB** inserts the record to a special insert buffer structure. The insert buffer is kept so small that it fits entirely in the buffer pool, and insertions can be done very fast.

Periodically, the insert buffer is merged into the secondary index trees in the database. Often it is possible to merge several insertions to the same page of the index tree, saving disk I/O operations. It has been measured that the insert buffer can speed up insertions into a table up to 15 times.

The insert buffer merging may continue to happen *after* the inserting transaction has been committed. In fact, it may continue to happen after a server shutdown and restart (see [Section 13.5.8.1, “Forcing InnoDB Recovery”](#)).

The insert buffer merging may take many hours, when many secondary indexes must be updated, and many rows have been inserted. During this time, disk I/O will be increased, which can cause significant slowdown on disk-bound queries. Another significant background I/O operation is the purge thread (see [Section 13.5.12, “Implementation of Multi-Versioning”](#)).

13.5.13.3. Adaptive Hash Indexes

If a table fits almost entirely in main memory, the fastest way to perform queries on it is to use hash indexes. **InnoDB** has a mechanism that monitors index searches made to the indexes defined for a table. If **InnoDB** notices that queries could benefit from building a hash index, it does so automatically.

Note that the hash index is always built based on an existing B-tree index on the table. **InnoDB** can build a hash index on a prefix of any length of the key defined for the B-tree, depending on the pattern of searches that **InnoDB** observes for the B-tree index. A hash index can be partial: It is not required that the whole B-tree index is cached in the buffer pool. **InnoDB** builds hash indexes on demand for those pages of the index that are often accessed.

In a sense, **InnoDB** tailors itself through the adaptive hash index mechanism to amply main memory, coming closer to the architecture of main-memory databases.

13.5.13.4. Physical Row Structure

The physical record structure for **InnoDB** tables is dependent on the row format specified when the table was created. For MySQL 5.1, by default **InnoDB** uses the **COMPACT** format, but the **REDUNDANT** format is available to retain compatibility with older versions of MySQL.

Records in InnoDB `ROW_FORMAT=REDUNDANT` tables have the following characteristics:

- Each index record contains a six-byte header. The header is used to link together consecutive records, and also in row-level locking.
- Records in the clustered index contain fields for all user-defined columns. In addition, there is a six-byte field for the transaction ID and a seven-byte field for the roll pointer.
- If no primary key was defined for a table, each clustered index record also contains a six-byte row ID field.
- Each secondary index record contains also all the fields defined for the clustered index key.
- A record contains also a pointer to each field of the record. If the total length of the fields in a record is less than 128 bytes, the pointer is one byte; otherwise, two bytes. The array of these pointers is called the record directory. The area where these pointers point is called the data part of the record.
- Internally, InnoDB stores fixed-length character columns such as `CHAR(10)` in a fixed-length format. InnoDB truncates trailing spaces from `VARCHAR` columns.
- An SQL `NULL` value reserves 1 or 2 bytes in the record directory. Besides that, an SQL `NULL` value reserves zero bytes in the data part of the record if stored in a variable length column. In a fixed-length column, it reserves the fixed length of the column in the data part of the record. The motivation behind reserving the fixed space for `NULL` values is that it enables an update of the column from `NULL` to a non-`NULL` value to be done in place without causing fragmentation of the index page.

Records in InnoDB `ROW_FORMAT=COMPACT` tables have the following characteristics:

- Each index record contains a five-byte header that may be preceded by a variable-length header. The header is used to link together consecutive records, and also in row-level locking.
- The record header contains a bit vector for indicating `NULL` columns. The bit vector occupies $(n\_nullable+7)/8$ bytes. Columns that are `NULL` will not occupy other space than the bit in this vector.
- For each non-`NULL` variable-length field, the record header contains the length of the column in one or two bytes. Two bytes will only be needed if part of the column is stored externally or the maximum length exceeds 255 bytes and the actual length exceeds 127 bytes.
- The record header is followed by the data contents of the columns. Columns that are `NULL` are omitted.
- Records in the clustered index contain fields for all user-defined columns. In addition, there is a six-byte field for the transaction ID and a seven-byte field for the roll pointer.
- If no primary key was defined for a table, each clustered index record also contains a six-byte row ID field.
- Each secondary index record contains also all the fields defined for the clustered index key.
- Internally, InnoDB stores fixed-length, fixed-width character columns such as `CHAR(10)` in a fixed-length format. InnoDB truncates trailing spaces from `VARCHAR` columns.
- Internally, InnoDB attempts to store UTF-8 `CHAR(n)` columns in `n` bytes by trimming trailing spaces. In `ROW_FORMAT=REDUNDANT`, such columns occupy $3*n$ bytes. The motivation behind reserving the minimum space `n` is that it in many cases enables an update of the column to be done in place without causing fragmentation of the index page.

The presence of the compact row format decreases row storage space by about 20% at the cost of increasing CPU use for some operations. If your workload is a typical one that is limited by cache hit rates and disk speed it is likely to be faster. If it is a rare case that is limited by CPU speed, it might be slower.

13.5.14. InnoDB File Space Management and Disk I/O

13.5.14.1. InnoDB Disk I/O

InnoDB uses simulated asynchronous disk I/O: InnoDB creates a number of threads to take care of I/O operations, such as read-ahead.

There are two read-ahead heuristics in **InnoDB**:

- In sequential read-ahead, if **InnoDB** notices that the access pattern to a segment in the tablespace is sequential, it posts in advance a batch of reads of database pages to the I/O system.
- In random read-ahead, if **InnoDB** notices that some area in a tablespace seems to be in the process of being fully read into the buffer pool, it posts the remaining reads to the I/O system.

InnoDB uses a novel file flush technique called *doublewrite*. It adds safety to recovery following an operating system crash or a power outage, and improves performance on most varieties of Unix by reducing the need for `fsync()` operations.

Doublewrite means that before writing pages to a data file, **InnoDB** first writes them to a contiguous tablespace area called the doublewrite buffer. Only after the write and the flush to the doublewrite buffer has completed does **InnoDB** write the pages to their proper positions in the data file. If the operating system crashes in the middle of a page write, **InnoDB** can later find a good copy of the page from the doublewrite buffer during recovery.

13.5.14.2. File Space Management

The data files that you define in the configuration file form the tablespace of **InnoDB**. The files are simply concatenated to form the tablespace. There is no striping in use. Currently, you cannot define where within the tablespace your tables are allocated. However, in a newly created tablespace, **InnoDB** allocates space starting from the first data file.

The tablespace consists of database pages with a default size of 16KB. The pages are grouped into extents of 64 consecutive pages. The “files” inside a tablespace are called *segments* in **InnoDB**. The term “rollback segment” is somewhat confusing because it actually contains many tablespace segments.

Two segments are allocated for each index in **InnoDB**. One is for non-leaf nodes of the B-tree, the other is for the leaf nodes. The idea here is to achieve better sequentiality for the leaf nodes, which contain the data.

When a segment grows inside the tablespace, **InnoDB** allocates the first 32 pages to it individually. After that **InnoDB** starts to allocate whole extents to the segment. **InnoDB** can add to a large segment up to 4 extents at a time to ensure good sequentiality of data.

Some pages in the tablespace contain bitmaps of other pages, and therefore a few extents in an **InnoDB** tablespace cannot be allocated to segments as a whole, but only as individual pages.

When you ask for available free space in the tablespace by issuing a `SHOW TABLE STATUS` statement, **InnoDB** reports the extents that are definitely free in the tablespace. **InnoDB** always reserves some extents for cleanup and other internal purposes; these reserved extents are not included in the free space.

When you delete data from a table, **InnoDB** contracts the corresponding B-tree indexes. Whether the freed space becomes available for other users depends on whether the pattern of deletes frees individual pages or extents to the tablespace. Dropping a table or deleting all rows from it is guaranteed to release the space to other users, but remember that deleted rows are physically removed only in an (automatic) purge operation after they are no longer needed for transaction rollbacks or consistent reads. (See [Section 13.5.12, “Implementation of Multi-Versioning”](#).)

13.5.14.3. Defragmenting a Table

If there are random insertions into or deletions from the indexes of a table, the indexes may become fragmented. Fragmentation means that the physical ordering of the index pages on the disk is not close to the index ordering of the records on the pages, or that there are many unused pages in the 64-page blocks that were allocated to the index.

A symptom of fragmentation is that a table takes more space than it “should” take. How much that is exactly, is difficult to determine. All **InnoDB** data and indexes are stored in B-trees, and their fill factor may vary from 50% to 100%. Another symptom of fragmentation is that a table scan such as this takes more time than it “should” take:

```
SELECT COUNT(*) FROM t WHERE a_non_indexed_column <> 12345;
```

(In the preceding query, we are “fooling” the SQL optimizer into scanning the clustered index, rather than a secondary index.) Most disks can read 10 to 50MB/s, which can be used to estimate how fast a table scan should run.

It can speed up index scans if you periodically perform a “null” `ALTER TABLE` operation:

```
ALTER TABLE tbl_name ENGINE=INNODB
```

That causes MySQL to rebuild the table. Another way to perform a defragmentation operation is to use `mysqldump` to dump the table to a text file, drop the table, and reload it from the dump file.

If the insertions to an index are always ascending and records are deleted only from the end, the **InnoDB** filespace management algorithm guarantees that fragmentation in the index does not occur.

13.5.15. InnoDB Error Handling

Error handling in **InnoDB** is not always the same as specified in the SQL standard. According to the standard, any error during an SQL statement should cause the rollback of that statement. **InnoDB** sometimes rolls back only part of the statement, or the whole transaction. The following items describe how **InnoDB** performs error handling:

- If you run out of file space in the tablespace, a MySQL `Table is full` error occurs and **InnoDB** rolls back the SQL statement.
- A transaction deadlock causes **InnoDB** to roll back the entire transaction. In the case of a lock wait timeout, **InnoDB** rolls back only the most recent SQL statement.

When a transaction rollback occurs due to a deadlock or lock wait timeout, it cancels the effect of the statements within the transaction. But if the start-transaction statement was `START TRANSACTION` or `BEGIN` statement, rollback does not cancel that statement. Further SQL statements become part of the transaction until the occurrence of `COMMIT`, `ROLLBACK`, or some SQL statement that causes an implicit commit.

- A duplicate-key error rolls back the SQL statement, if you have not specified the `IGNORE` option in your statement.
- A `row too long error` rolls back the SQL statement.
- Other errors are mostly detected by the MySQL layer of code (above the **InnoDB** storage engine level), and they roll back the corresponding SQL statement. Locks are not released in a rollback of a single SQL statement.

During implicit rollbacks, as well as during the execution of an explicit `ROLLBACK` SQL command, `SHOW PROCESSLIST` displays `Rolling back` in the `State` column for the relevant connection.

13.5.15.1. InnoDB Error Codes

The following is a non-exhaustive list of common **InnoDB**-specific errors that you may encounter, with information about why each occurs and how to resolve the problem.

- **1005 (ER_CANT_CREATE_TABLE)**
Cannot create table. If the error message refers to `errno` 150, table creation failed because a foreign key constraint was not correctly formed. If the error message refers to `errno` -1, table creation probably failed because the table includes a column name that matched the name of an internal **InnoDB** table.
- **1016 (ER_CANT_OPEN_FILE)**
Cannot find the **InnoDB** table from the **InnoDB** data files, although the `.frm` file for the table exists. See [Section 13.5.17.1, “Troubleshooting InnoDB Data Dictionary Operations”](#).
- **1114 (ER_RECORD_FILE_FULL)**
InnoDB has run out of free space in the tablespace. You should reconfigure the tablespace to add a new data file.
- **1205 (ER_LOCK_WAIT_TIMEOUT)**
Lock wait timeout expired. Transaction was rolled back.
- **1213 (ER_LOCK_DEADLOCK)**
Transaction deadlock. You should rerun the transaction.
- **1216 (ER_NO_REFERENCED_ROW)**

You are trying to add a row but there is no parent row, and a foreign key constraint fails. You should add the parent row first.

- [1217 \(ER_ROW_IS_REFERENCED\)](#)

You are trying to delete a parent row that has children, and a foreign key constraint fails. You should delete the children first.

13.5.15.2. Operating System Error Codes

To print the meaning of an operating system error number, use the [perror](#) program that comes with the MySQL distribution.

The following table provides a list of some common Linux system error codes. For a more complete list, see [Linux source code](#).

- [1 \(EPERM\)](#)
Operation not permitted
- [2 \(ENOENT\)](#)
No such file or directory
- [3 \(ESRCH\)](#)
No such process
- [4 \(EINTR\)](#)
Interrupted system call
- [5 \(EIO\)](#)
I/O error
- [6 \(ENXIO\)](#)
No such device or address
- [7 \(E2BIG\)](#)
Arg list too long
- [8 \(ENOEXEC\)](#)
Exec format error
- [9 \(EBADF\)](#)
Bad file number
- [10 \(ECHILD\)](#)
No child processes
- [11 \(EAGAIN\)](#)
Try again
- [12 \(ENOMEM\)](#)
Out of memory
- [13 \(EACCES\)](#)
Permission denied

- [14 \(EFAULT\)](#)
Bad address
- [15 \(ENOTBLK\)](#)
Block device required
- [16 \(EBUSY\)](#)
Device or resource busy
- [17 \(EEXIST\)](#)
File exists
- [18 \(EXDEV\)](#)
Cross-device link
- [19 \(ENODEV\)](#)
No such device
- [20 \(ENOTDIR\)](#)
Not a directory
- [21 \(EISDIR\)](#)
Is a directory
- [22 \(EINVAL\)](#)
Invalid argument
- [23 \(ENFILE\)](#)
File table overflow
- [24 \(EMFILE\)](#)
Too many open files
- [25 \(ENOTTY\)](#)
Inappropriate ioctl for device
- [26 \(ETXTBSY\)](#)
Text file busy
- [27 \(EFBIG\)](#)
File too large
- [28 \(ENOSPC\)](#)
No space left on device
- [29 \(ESPIPE\)](#)
Illegal seek
- [30 \(EROFS\)](#)
Read-only file system

- 31 (EMLINK)

Too many links

The following table provides a list of some common Windows system error codes. For a complete list see the [Microsoft Web site](#).

- 1 (ERROR_INVALID_FUNCTION)

Incorrect function.

- 2 (ERROR_FILE_NOT_FOUND)

The system cannot find the file specified.

- 3 (ERROR_PATH_NOT_FOUND)

The system cannot find the path specified.

- 4 (ERROR_TOO_MANY_OPEN_FILES)

The system cannot open the file.

- 5 (ERROR_ACCESS_DENIED)

Access is denied.

- 6 (ERROR_INVALID_HANDLE)

The handle is invalid.

- 7 (ERROR_ARENA_TRASHED)

The storage control blocks were destroyed.

- 8 (ERROR_NOT_ENOUGH_MEMORY)

Not enough storage is available to process this command.

- 9 (ERROR_INVALID_BLOCK)

The storage control block address is invalid.

- 10 (ERROR_BAD_ENVIRONMENT)

The environment is incorrect.

- 11 (ERROR_BAD_FORMAT)

An attempt was made to load a program with an incorrect format.

- 12 (ERROR_INVALID_ACCESS)

The access code is invalid.

- 13 (ERROR_INVALID_DATA)

The data is invalid.

- 14 (ERROR_OUTOFMEMORY)

Not enough storage is available to complete this operation.

- 15 (ERROR_INVALID_DRIVE)

The system cannot find the drive specified.

- **16 (ERROR_CURRENT_DIRECTORY)**
The directory cannot be removed.
- **17 (ERROR_NOT_SAME_DEVICE)**
The system cannot move the file to a different disk drive.
- **18 (ERROR_NO_MORE_FILES)**
There are no more files.
- **19 (ERROR_WRITE_PROTECT)**
The media is write protected.
- **20 (ERROR_BAD_UNIT)**
The system cannot find the device specified.
- **21 (ERROR_NOT_READY)**
The device is not ready.
- **22 (ERROR_BAD_COMMAND)**
The device does not recognize the command.
- **23 (ERROR_CRC)**
Data error (cyclic redundancy check).
- **24 (ERROR_BAD_LENGTH)**
The program issued a command but the command length is incorrect.
- **25 (ERROR_SEEK)**
The drive cannot locate a specific area or track on the disk.
- **26 (ERROR_NOT_DOS_DISK)**
The specified disk or diskette cannot be accessed.
- **27 (ERROR_SECTOR_NOT_FOUND)**
The drive cannot find the sector requested.
- **28 (ERROR_OUT_OF_PAPER)**
The printer is out of paper.
- **29 (ERROR_WRITE_FAULT)**
The system cannot write to the specified device.
- **30 (ERROR_READ_FAULT)**
The system cannot read from the specified device.
- **31 (ERROR_GEN_FAILURE)**
A device attached to the system is not functioning.
- **32 (ERROR_SHARING_VIOLATION)**
The process cannot access the file because it is being used by another process.

- **33 (ERROR_LOCK_VIOLATION)**

The process cannot access the file because another process has locked a portion of the file.

- **34 (ERROR_WRONG_DISK)**

The wrong diskette is in the drive. Insert %2 (Volume Serial Number: %3) into drive %1.

- **36 (ERROR_SHARING_BUFFER_EXCEEDED)**

Too many files opened for sharing.

- **38 (ERROR_HANDLE_EOF)**

Reached the end of the file.

- **39 (ERROR_HANDLE_DISK_FULL)**

The disk is full.

- **87 (ERROR_INVALID_PARAMETER)**

The parameter is incorrect. (If this error occurs on Windows and you have enabled `innodb_file_per_table` in a server option file, add the line `innodb_flush_method=unbuffered` to the file as well.)

- **112 (ERROR_DISK_FULL)**

The disk is full.

- **123 (ERROR_INVALID_NAME)**

The filename, directory name, or volume label syntax is incorrect.

- **1450 (ERROR_NO_SYSTEM_RESOURCES)**

Insufficient system resources exist to complete the requested service.

13.5.16. Restrictions on InnoDB Tables

- **Warning:** Do not convert MySQL system tables in the `mysql` database from `MyISAM` to `InnoDB` tables! This is an unsupported operation. If you do this, MySQL does not restart until you restore the old system tables from a backup or re-generate them with the `mysql_install_db` script.

Warning

It is not a good idea to configure `InnoDB` to use datafiles or logfiles on NFS volumes. Otherwise, the files might be locked by other processes and become unavailable for use by MySQL.

- A table cannot contain more than 1000 columns.
- The internal maximum key length is 3500 bytes, but MySQL itself restricts this to 1024 bytes.
- The maximum row length, except for `VARBINARY`, `VARCHAR`, `BLOB` and `TEXT` columns, is slightly less than half of a database page. That is, the maximum row length is about 8000 bytes. `LONGLOB` and `LONGTEXT` columns must be less than 4GB, and the total row length, including also `BLOB` and `TEXT` columns, must be less than 4GB. `InnoDB` stores the first 768 bytes of a `VARBINARY`, `VARCHAR`, `BLOB`, or `TEXT` column in the row, and the rest into separate pages.
- Although `InnoDB` supports row sizes larger than 65535 internally, you cannot define a row containing `VARBINARY` or `VARCHAR` columns with a combined size larger than 65535:

```
mysql> CREATE TABLE t (a VARCHAR(8000), b VARCHAR(10000),
-> c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
-> f VARCHAR(10000), g VARCHAR(10000)) ENGINE=InnoDB;
ERROR 1118 (42000): Row size too large. The maximum row size for the
used table type, not counting BLOBs, is 65535. You have to change some
columns to TEXT or BLOBs
```

- On some older operating systems, files must be less than 2GB. This is not a limitation of **InnoDB** itself, but if you require a large tablespace, you will need to configure it using several smaller data files rather than one or a file large data files.
- The combined size of the **InnoDB** log files must be less than 4GB.
- The minimum tablespace size is 10MB. The maximum tablespace size is four billion database pages (64TB). This is also the maximum size for a table.
- **InnoDB** tables do not support **FULLTEXT** indexes.
- **InnoDB** tables support spatial types, but not indexes on them.
- **ANALYZE TABLE** determines index cardinality (as displayed in the **Cardinality** column of **SHOW INDEX** output) by doing ten random dives to each of the index trees and updating index cardinality estimates accordingly. Note that because these are only estimates, repeated runs of **ANALYZE TABLE** may produce different numbers. This makes **ANALYZE TABLE** fast on **InnoDB** tables but not 100% accurate as it doesn't take all rows into account.

MySQL uses index cardinality estimates only in join optimization. If some join is not optimized in the right way, you can try using **ANALYZE TABLE**. In the few cases that **ANALYZE TABLE** doesn't produce values good enough for your particular tables, you can use **FORCE INDEX** with your queries to force the use of a particular index, or set the **max_seeks_for_key** system variable to ensure that MySQL prefers index lookups over table scans. See [Section 5.2.3, “System Variables”](#), and [Section B.1.6, “Optimizer-Related Issues”](#).

- **SHOW TABLE STATUS** does not give accurate statistics on **InnoDB** tables, except for the physical size reserved by the table. The row count is only a rough estimate used in SQL optimization.
- **InnoDB** does not keep an internal count of rows in a table. (In practice, this would be somewhat complicated due to multi-versioning.) To process a **SELECT COUNT(*) FROM t** statement, **InnoDB** must scan an index of the table, which takes some time if the index is not entirely in the buffer pool. To get a fast count, you have to use a counter table you create yourself and let your application update it according to the inserts and deletes it does. If your table does not change often, using the MySQL query cache is a good solution. **SHOW TABLE STATUS** also can be used if an approximate row count is sufficient. See [Section 13.5.11, “InnoDB Performance Tuning Tips”](#).
- On Windows, **InnoDB** always stores database and table names internally in lowercase. To move databases in binary format from Unix to Windows or from Windows to Unix, you should always use explicitly lowercase names when creating databases and tables.
- For an **AUTO_INCREMENT** column, you must always define an index for the table, and that index must contain just the **AUTO_INCREMENT** column. In **MyISAM** tables, the **AUTO_INCREMENT** column may be part of a multi-column index.
- While initializing a previously specified **AUTO_INCREMENT** column on a table, **InnoDB** sets an exclusive lock on the end of the index associated with the **AUTO_INCREMENT** column. In accessing the auto-increment counter, **InnoDB** uses a specific table lock mode **AUTO-INC** where the lock lasts only to the end of the current SQL statement, not to the end of the entire transaction. Note that other clients cannot insert into the table while the **AUTO-INC** table lock is held; see [Section 13.5.10.2, “InnoDB and AUTO-COMMIT”](#).
- When you restart the MySQL server, **InnoDB** may reuse an old value that was generated for an **AUTO_INCREMENT** column but never stored (that is, a value that was generated during an old transaction that was rolled back).
- When an **AUTO_INCREMENT** column runs out of values, **InnoDB** wraps a **BIGINT** to **-9223372036854775808** and **BIGINT UNSIGNED** to **1**. However, **BIGINT** values have 64 bits, so do note that if you were to insert one million rows per second, it would still take nearly three hundred thousand years before **BIGINT** reached its upper bound. With all other integer type columns, a duplicate-key error results. This is similar to how **MyISAM** works, because it is mostly general MySQL behavior and not about any storage engine in particular.
- **DELETE FROM tbl_name** does not regenerate the table but instead deletes all rows, one by one.
- Under some conditions, **TRUNCATE tbl_name** for an **InnoDB** table is mapped to **DELETE FROM tbl_name** and doesn't reset the **AUTO_INCREMENT** counter. See [Section 12.2.9, “TRUNCATE Syntax”](#).
- In MySQL 5.1, the MySQL **LOCK TABLES** operation acquires two locks on each table if **innodb_table_locks=1** (the default). In addition to a table lock on the MySQL layer, it also acquires an **InnoDB** table lock. Older versions of MySQL did not acquire **InnoDB** table locks; the old behavior can be selected by setting **innodb_table_locks=0**. If no **InnoDB** table lock is acquired, **LOCK TABLES** completes even if some records of the tables are being locked by other transactions.

- All **InnoDB** locks held by a transaction are released when the transaction is committed or aborted. Thus, it does not make much sense to invoke **LOCK TABLES** on **InnoDB** tables in **AUTOCOMMIT=1** mode, because the acquired **InnoDB** table locks would be released immediately.
- Sometimes it would be useful to lock further tables in the course of a transaction. Unfortunately, **LOCK TABLES** in MySQL performs an implicit **COMMIT** and **UNLOCK TABLES**. An **InnoDB** variant of **LOCK TABLES** has been planned that can be executed in the middle of a transaction.
- The **LOAD TABLE FROM MASTER** statement for setting up replication slave servers does not work for **InnoDB** tables. A work-around is to alter the table to **MyISAM** on the master, then do the load, and after that alter the master table back to **InnoDB**. Do not do this if the tables use **InnoDB**-specific features such as foreign keys.
- The default database page size in **InnoDB** is 16KB. By recompiling the code, you can set it to values ranging from 8KB to 64KB. You must update the values of **UNIV_PAGE_SIZE** and **UNIV_PAGE_SIZE_SHIFT** in the **univ.i** source file.
- Currently, triggers are not activated by cascaded foreign key actions.
- **InnoDB** has a limit of 1023 concurrent transactions that have created undo records by modifying data. Workarounds include keeping transactions as small and fast as possible, delaying changes until near the end of the transaction, and using stored routines to reduce client-server latency delays. Applications should commit transactions before doing time-consuming client-side operations.

13.5.17. InnoDB Troubleshooting

The following general guidelines apply to troubleshooting **InnoDB** problems:

- When an operation fails or you suspect a bug, you should look at the MySQL server error log, which is the file in the data directory that has a suffix of **.err**.
- When troubleshooting, it is usually best to run the MySQL server from the command prompt, rather than through the **mysqld_safe** wrapper or as a Windows service. You can then see what **mysqld** prints to the console, and so have a better grasp of what is going on. On Windows, you must start the server with the **--console** option to direct the output to the console window.
- Use the **InnoDB** Monitors to obtain information about a problem (see [Section 13.5.11.1, “SHOW ENGINE INNODB STATUS and the InnoDB Monitors”](#)). If the problem is performance-related, or your server appears to be hung, you should use **innodb_monitor** to print information about the internal state of **InnoDB**. If the problem is with locks, use **innodb_lock_monitor**. If the problem is in creation of tables or other data dictionary operations, use **innodb_table_monitor** to print the contents of the **InnoDB** internal data dictionary.
- If you suspect that a table is corrupt, run **CHECK TABLE** on that table.

MySQL Enterprise

The MySQL Enterprise Monitor provides a number of advisors specifically designed for monitoring **InnoDB** tables. In some cases, these advisors can anticipate potential problems. For more information see <http://www.mysql.com/products/enterprise/advisors.html>.

13.5.17.1. Troubleshooting InnoDB Data Dictionary Operations

A specific issue with tables is that the MySQL server keeps data dictionary information in **.frm** files it stores in the database directories, whereas **InnoDB** also stores the information into its own data dictionary inside the tablespace files. If you move **.frm** files around, or if the server crashes in the middle of a data dictionary operation, the locations of the **.frm** files may end up out of synchrony with the locations recorded in the **InnoDB** internal data dictionary.

A symptom of an out-of-sync data dictionary is that a **CREATE TABLE** statement fails. If this occurs, you should look in the server's error log. If the log says that the table already exists inside the **InnoDB** internal data dictionary, you have an orphaned table inside the **InnoDB** tablespace files that has no corresponding **.frm** file. The error message looks like this:

```
InnoDB: Error: table test/parent already exists in InnoDB internal
InnoDB: data dictionary. Have you deleted the .frm file
InnoDB: and not used DROP TABLE? Have you used DROP DATABASE
InnoDB: for InnoDB tables in MySQL version <= 3.23.43?
InnoDB: See the Restrictions section of the InnoDB manual.
InnoDB: You can drop the orphaned table inside InnoDB by
InnoDB: creating an InnoDB table with the same name in another
```

```
InnoDB: database and moving the .frm file to the current database.
InnoDB: Then MySQL thinks the table exists, and DROP TABLE will
InnoDB: succeed.
```

You can drop the orphaned table by following the instructions given in the error message. If you are still unable to use `DROP TABLE` successfully, the problem may be due to name completion in the `mysql` client. To work around this problem, start the `mysql` client with the `--skip-auto-rehash` option and try `DROP TABLE` again. (With name completion on, `mysql` tries to construct a list of table names, which fails when a problem such as just described exists.)

Another symptom of an out-of-sync data dictionary is that MySQL prints an error that it cannot open a `.InnoDB` file:

```
ERROR 1016: Can't open file: 'child2.InnoDB'. (errno: 1)
```

In the error log you can find a message like this:

```
InnoDB: Cannot find table test/child2 from the internal data dictionary
InnoDB: of InnoDB though the .frm file for the table exists. Maybe you
InnoDB: have deleted and recreated InnoDB data files but have forgotten
InnoDB: to delete the corresponding .frm files of InnoDB tables?
```

This means that there is an orphaned `.frm` file without a corresponding table inside `InnoDB`. You can drop the orphaned `.frm` file by deleting it manually.

If MySQL crashes in the middle of an `ALTER TABLE` operation, you may end up with an orphaned temporary table inside the `InnoDB` tablespace. Using `innodb_table_monitor` you can see listed a table whose name is `#sql-...`. You can perform SQL statements on tables whose name contains the character `#` if you enclose the name within backticks. Thus, you can drop such an orphaned table like any other orphaned table using the method described earlier. Note that to copy or rename a file in the Unix shell, you need to put the file name in double quotes if the file name contains `#`.

13.6. The MERGE Storage Engine

The `MERGE` storage engine, also known as the `MRG_MyISAM` engine, is a collection of identical `MyISAM` tables that can be used as one. “Identical” means that all tables have identical column and index information. You cannot merge `MyISAM` tables in which the columns are listed in a different order, do not have exactly the same columns, or have the indexes in different order. However, any or all of the `MyISAM` tables can be compressed with `myisampack`. See [Section 7.7, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#). Differences in table options such as `AVG_ROW_LENGTH`, `MAX_ROWS`, or `PACK_KEYS` do not matter.

When you create a `MERGE` table, MySQL creates two files on disk. The files have names that begin with the table name and have an extension to indicate the file type. An `.frm` file stores the table format, and an `.MRG` file contains the names of the tables that should be used as one. The tables do not have to be in the same database as the `MERGE` table itself.

You can use `SELECT`, `DELETE`, `UPDATE`, and `INSERT` on `MERGE` tables. You must have `SELECT`, `UPDATE`, and `DELETE` privileges on the `MyISAM` tables that you map to a `MERGE` table.

Note

The use of `MERGE` tables entails the following security issue: If a user has access to `MyISAM` table `t`, that user can create a `MERGE` table `m` that accesses `t`. However, if the user's privileges on `t` are subsequently revoked, the user can continue to access `t` by doing so through `m`. If this behavior is undesirable, you can start the server with the new `--skip-merge` option to disable the `MERGE` storage engine. This option is available as of MySQL 5.1.12.

If you `DROP` the `MERGE` table, you are dropping only the `MERGE` specification. The underlying tables are not affected.

To create a `MERGE` table, you must specify a `UNION=(list-of-tables)` clause that indicates which `MyISAM` tables you want to use as one. You can optionally specify an `INSERT_METHOD` option if you want inserts for the `MERGE` table to take place in the first or last table of the `UNION` list. Use a value of `FIRST` or `LAST` to cause inserts to be made in the first or last table, respectively. If you do not specify an `INSERT_METHOD` option or if you specify it with a value of `NO`, attempts to insert rows into the `MERGE` table result in an error.

The following example shows how to create a `MERGE` table:

```
mysql> CREATE TABLE t1 (
->   a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
->   message CHAR(20)) ENGINE=MyISAM;
mysql> CREATE TABLE t2 (
->   a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
```

```

-> message CHAR(20)) ENGINE=MyISAM;
mysql> INSERT INTO t1 (message) VALUES ('Testing'),('table'),('t1');
mysql> INSERT INTO t2 (message) VALUES ('Testing'),('table'),('t2');
mysql> CREATE TABLE total (
->   a INT NOT NULL AUTO_INCREMENT,
->   message CHAR(20), INDEX(a))
->   ENGINE=MERGE UNION=(t1,t2) INSERT_METHOD=LAST;

```

Note that the `a` column is indexed as a **PRIMARY KEY** in the underlying **MyISAM** tables, but not in the **MERGE** table. There it is indexed but not as a **PRIMARY KEY** because a **MERGE** table cannot enforce uniqueness over the set of underlying tables.

In MySQL 5.1.15 and later, when a table that is part of a **MERGE** table is opened, the following checks are applied before opening each table. If any table fails the conformance checks, then the operation that triggered the opening of the table will fail. The conformance checks applied to each table are:

- Table must have exactly the same amount of columns that **MERGE** table has.
- Column order in the **MERGE** table must match the column order in the underlying tables.
- Additionally, the specification for each column in the parent **MERGE** table and the underlying table are compared. For each column, MySQL checks:
 - Column type in the underlying table equals the column type of **MERGE** table.
 - Column length in the underlying table equals the column length of **MERGE** table.
 - Column of underlying table and column of **MERGE** table can be **NULL**.
- Underlying table must have at least the same amount of keys that merge table has. The underlying table may have more keys than the **MERGE** table, but cannot have less.
- For each key:
 - Check if the key type of underlying table equals the key type of merge table.
 - Check if number of key parts (i.e. multiple columns within a compound key) in the underlying table key definition equals the number of key parts in merge table key definition.
 - For each key part:
 - Check if key part lengths are equal.
 - Check if key part types are equal.
 - Check if key part languages are equal.
 - Check if key part can be **NULL**.

After creating the **MERGE** table, you can issue queries that operate on the group of tables as a whole:

```

mysql> SELECT * FROM total;
+-----+-----+
| a | message |
+-----+-----+
| 1 | Testing |
| 2 | table   |
| 3 | t1      |
| 1 | Testing |
| 2 | table   |
| 3 | t2      |
+-----+-----+

```

To remap a **MERGE** table to a different collection of **MyISAM** tables, you can use one of the following methods:

- **DROP** the **MERGE** table and re-create it.
- Use **ALTER TABLE *tbl_name* UNION=(...)** to change the list of underlying tables.

MERGE tables can help you solve the following problems:

- Easily manage a set of log tables. For example, you can put data from different months into separate tables, compress some of them with **myisampack**, and then create a **MERGE** table to use them as one.
- Obtain more speed. You can split a big read-only table based on some criteria, and then put individual tables on different disks. A **MERGE** table on this could be much faster than using the big table.
- Perform more efficient searches. If you know exactly what you are looking for, you can search in just one of the split tables for some queries and use a **MERGE** table for others. You can even have many different **MERGE** tables that use overlapping sets of tables.
- Perform more efficient repairs. It is easier to repair individual tables that are mapped to a **MERGE** table than to repair a single large table.
- Instantly map many tables as one. A **MERGE** table need not maintain an index of its own because it uses the indexes of the individual tables. As a result, **MERGE** table collections are very fast to create or remap. (Note that you must still specify the index definitions when you create a **MERGE** table, even though no indexes are created.)
- If you have a set of tables from which you create a large table on demand, you should instead create a **MERGE** table on them on demand. This is much faster and saves a lot of disk space.
- Exceed the file size limit for the operating system. Each **MyISAM** table is bound by this limit, but a collection of **MyISAM** tables is not.
- You can create an alias or synonym for a **MyISAM** table by defining a **MERGE** table that maps to that single table. There should be no really notable performance impact from doing this (only a couple of indirect calls and **memcpy()** calls for each read).

The disadvantages of **MERGE** tables are:

- You can use only identical **MyISAM** tables for a **MERGE** table.
- You cannot use a number of **MyISAM** features in **MERGE** tables. For example, you cannot create **FULLTEXT** indexes on **MERGE** tables. (You can, of course, create **FULLTEXT** indexes on the underlying **MyISAM** tables, but you cannot search the **MERGE** table with a full-text search.)
- If the **MERGE** table is non-temporary, all underlying **MyISAM** tables must be non-temporary, too. If the **MERGE** table is temporary, the **MyISAM** tables can be any mix of temporary and non-temporary.
- **MERGE** tables use more file descriptors. If 10 clients are using a **MERGE** table that maps to 10 tables, the server uses $(10 \times 10) + 10$ file descriptors. (10 data file descriptors for each of the 10 clients, and 10 index file descriptors shared among the clients.)
- Key reads are slower. When you read a key, the **MERGE** storage engine needs to issue a read on all underlying tables to check which one most closely matches the given key. To read the next key, the **MERGE** storage engine needs to search the read buffers to find the next key. Only when one key buffer is used up does the storage engine need to read the next key block. This makes **MERGE** keys much slower on **eq_ref** searches, but not much slower on **ref** searches. See [Section 6.2.1, “Optimizing Queries with EXPLAIN”](#), for more information about **eq_ref** and **ref**.

Additional resources

- A forum dedicated to the **MERGE** storage engine is available at <http://forums.mysql.com/list.php?93>.

13.6.1. **MERGE** Table Problems

The following are known problems with **MERGE** tables:

- If you use **ALTER TABLE** to change a **MERGE** table to another storage engine, the mapping to the underlying tables is lost. Instead, the rows from the underlying **MyISAM** tables are copied into the altered table, which then uses the specified storage engine.
- **REPLACE** does not work.

- **MERGE** tables do not support partitioning. That is, you cannot partition a **MERGE** table, nor can any of a **MERGE** table's underlying **MyISAM** tables be partitioned.
- You cannot use **REPAIR TABLE**, **OPTIMIZE TABLE**, **DROP TABLE**, **ALTER TABLE**, **DELETE** without a **WHERE** clause, **TRUNCATE TABLE**, or **ANALYZE TABLE** on any of the tables that are mapped into an open **MERGE** table. If you do so, the **MERGE** table may still refer to the original table, which yields unexpected results. The easiest way to work around this deficiency is to ensure that no **MERGE** tables remain open by issuing a **FLUSH TABLES** statement prior to performing any of those operations.

The unexpected results include the possibility that the operation on the **MERGE** table will report table corruption. However, if this occurs after operations on the underlying **MyISAM** tables such as those listed in the previous paragraph (**REPAIR TABLE**, **OPTIMIZE TABLE**, and so forth), the corruption message is spurious. To deal with this, issue a **FLUSH TABLES** statement after modifying the **MyISAM** tables.

- **DROP TABLE** on a table that is in use by a **MERGE** table does not work on Windows because the **MERGE** storage engine's table mapping is hidden from the upper layer of MySQL. Windows does not allow open files to be deleted, so you first must flush all **MERGE** tables (with **FLUSH TABLES**) or drop the **MERGE** table before dropping the table.
- A **MERGE** table cannot maintain uniqueness constraints over the entire table. When you perform an **INSERT**, the data goes into the first or last **MyISAM** table (depending on the value of the **INSERT_METHOD** option). MySQL ensures that unique key values remain unique within that **MyISAM** table, but not across all the tables in the collection.
- In MySQL 5.1.15 and later, the definition of the **MyISAM** tables and the **MERGE** table are checked when the tables are accessed (for example, as part of a **SELECT** or **INSERT** statement). The checks ensure that the definitions of the tables and the parent **MERGE** table definition match by comparing column order, types, sizes and associated indexes. If there is a difference between the tables then an error will be returned and the statement will fail.

Because these checks take place when the tables are opened, any changes to the definition of a single, including column changes, column ordering and engine alterations will cause the statement to fail.

In MySQL 5.1.14 and earlier:

- When you create or alter **MERGE** table, there is no check to ensure that the underlying tables are existing **MyISAM** tables and have identical structures. When the **MERGE** table is used, MySQL checks that the row length for all mapped tables is equal, but this is not foolproof. If you create a **MERGE** table from dissimilar **MyISAM** tables, you are very likely to run into strange problems.
- Similarly, if you create a **MERGE** table from non-**MyISAM** tables, or if you drop an underlying table or alter it to be a non-**MyISAM** table, no error for the **MERGE** table occurs until later when you attempt to use it.
- Because the underlying **MyISAM** tables need not exist when the **MERGE** table is created, you can create the tables in any order, as long as you do not use the **MERGE** table until all of its underlying tables are in place. Also, if you can ensure that a **MERGE** table will not be used during a given period, you can perform maintenance operations on the underlying tables, such as backing up or restoring them, altering them, or dropping and recreating them. It is not necessary to redefine the **MERGE** table temporarily to exclude the underlying tables while you are operating on them.
- The order of indexes in the **MERGE** table and its underlying tables should be the same. If you use **ALTER TABLE** to add a **UNIQUE** index to a table used in a **MERGE** table, and then use **ALTER TABLE** to add a non-unique index on the **MERGE** table, the index ordering is different for the tables if there was already a non-unique index in the underlying table. (This happens because **ALTER TABLE** puts **UNIQUE** indexes before non-unique indexes to facilitate rapid detection of duplicate keys.) Consequently, queries on tables with such indexes may return unexpected results.
- If you encounter an error message similar to **ERROR 1017 (HY000): Can't find file: 'mm.MRG' (errno: 2)** it generally indicates that some of the base tables are not using the **MyISAM** storage engine. Confirm that all tables are **MyISAM**.
- There is a limit of 2^{32} (~4.295E+09) rows to a **MERGE** table, just as there is with a **MyISAM**, it is therefore not possible to merge multiple **MyISAM** tables that exceed this limitation. However, you build MySQL with the **--with-big-tables** option then the row limitation is increased to $(2^{32})^2$ (1.844E+19) rows. See [Section 2.9.2, "Typical configure Options"](#). Beginning with MySQL 5.0.4 all standard binaries are built with this option.
- The **MERGE** storage engine does not support **INSERT DELAYED** statements.

As of MySQL 5.1.20, if a **MERGE** table cannot be opened or used because of a problem with an underlying table, **CHECK TABLE** displays information about which table caused the problem.

13.7. The MEMORY (HEAP) Storage Engine

The **MEMORY** storage engine creates tables with contents that are stored in memory. Formerly, these were known as **HEAP** tables. **MEMORY** is the preferred term, although **HEAP** remains supported for backward compatibility.

Each **MEMORY** table is associated with one disk file. The filename begins with the table name and has an extension of **.frm** to indicate that it stores the table definition.

To specify explicitly that you want to create a **MEMORY** table, indicate that with an **ENGINE** table option:

```
CREATE TABLE t (i INT) ENGINE = MEMORY;
```

As indicated by the name, **MEMORY** tables are stored in memory. They use hash indexes by default, which makes them very fast, and very useful for creating temporary tables. However, when the server shuts down, all rows stored in **MEMORY** tables are lost. The tables themselves continue to exist because their definitions are stored in **.frm** files on disk, but they are empty when the server restarts.

This example shows how you might create, use, and remove a **MEMORY** table:

```
mysql> CREATE TABLE test ENGINE=MEMORY
-> SELECT ip,SUM(downloads) AS down
-> FROM log_table GROUP BY ip;
mysql> SELECT COUNT(ip),AVG(down) FROM test;
mysql> DROP TABLE test;
```

MEMORY tables have the following characteristics:

- Space for **MEMORY** tables is allocated in small blocks. Tables use 100% dynamic hashing for inserts. No overflow area or extra key space is needed. No extra space is needed for free lists. Deleted rows are put in a linked list and are reused when you insert new data into the table. **MEMORY** tables also have none of the problems commonly associated with deletes plus inserts in hashed tables.
- **MEMORY** tables can have up to 32 indexes per table, 16 columns per index and a maximum key length of 500 bytes.
- The **MEMORY** storage engine implements both **HASH** and **BTREE** indexes. You can specify one or the other for a given index by adding a **USING** clause as shown here:

```
CREATE TABLE lookup
(id INT, INDEX USING HASH (id))
ENGINE = MEMORY;
CREATE TABLE lookup
(id INT, INDEX USING BTREE (id))
ENGINE = MEMORY;
```

General characteristics of B-tree and hash indexes are described in [Section 6.4.5, “How MySQL Uses Indexes”](#).

- You can have non-unique keys in a **MEMORY** table. (This is an uncommon feature for implementations of hash indexes.)
- If you have a hash index on a **MEMORY** table that has a high degree of key duplication (many index entries containing the same value), updates to the table that affect key values and all deletes are significantly slower. The degree of this slowdown is proportional to the degree of duplication (or, inversely proportional to the index cardinality). You can use a **BTREE** index to avoid this problem.
- Columns that are indexed can contain **NULL** values.
- **MEMORY** tables use a fixed-length row storage format.
- **MEMORY** tables cannot contain **BLOB** or **TEXT** columns.
- **MEMORY** includes support for **AUTO_INCREMENT** columns.
- You can use **INSERT DELAYED** with **MEMORY** tables. See [Section 12.2.4.2, “INSERT DELAYED Syntax”](#).
- **MEMORY** tables are shared among all clients (just like any other non-**TEMPORARY** table).
- **MEMORY** table contents are stored in memory, which is a property that **MEMORY** tables share with internal tables that the server creates on the fly while processing queries. However, the two types of tables differ in that **MEMORY** tables are not subject to storage conversion, whereas internal tables are:

- If an internal table becomes too large, the server automatically converts it to an on-disk table. The size limit is determined by the value of the `tmp_table_size` system variable.
- `MEMORY` tables are never converted to disk tables. To ensure that you don't accidentally do anything foolish, you can set the `max_heap_table_size` system variable to impose a maximum size on `MEMORY` tables. For individual tables, you can also specify a `MAX_ROWS` table option in the `CREATE TABLE` statement.
- The server needs sufficient memory to maintain all `MEMORY` tables that are in use at the same time.
- Memory used by a `MEMORY` table is not reclaimed if you delete individual rows from the table. Memory is only reclaimed when the entire table is deleted. Memory that was previously used for rows that have been deleted will be re-used for new rows only within the same table. To free up the memory used by rows that have been deleted you should use `ALTER TABLE ENGINE=MEMORY` to force a table rebuild.

To free all the memory used by a `MEMORY` table when you no longer require its contents, you should execute `DELETE` or `TRUNCATE TABLE`, or remove the table altogether using `DROP TABLE`.

- If you want to populate a `MEMORY` table when the MySQL server starts, you can use the `--init-file` option. For example, you can put statements such as `INSERT INTO ... SELECT` or `LOAD DATA INFILE` into this file to load the table from a persistent data source. See [Section 5.2.2, “Command Options”](#), and [Section 12.2.5, “LOAD DATA INFILE Syntax”](#).
- If you are using replication, the master server's `MEMORY` tables become empty when it is shut down and restarted. However, a slave is not aware that these tables have become empty, so it returns out-of-date content if you select data from them. When a `MEMORY` table is used on the master for the first time since the master was started, a `DELETE` statement is written to the master's binary log automatically, thus synchronizing the slave to the master again. Note that even with this strategy, the slave still has outdated data in the table during the interval between the master's restart and its first use of the table. However, if you use the `--init-file` option to populate the `MEMORY` table on the master at startup, it ensures that this time interval is zero.
- The memory needed for one row in a `MEMORY` table is calculated using the following expression:

```
SUM_OVER_ALL_BTREE_KEYS(max_length_of_key + sizeof(char*) × 4)
+ SUM_OVER_ALL_HASH_KEYS(sizeof(char*) × 2)
+ ALIGN(length_of_row+1, sizeof(char*))
```

`ALIGN()` represents a round-up factor to cause the row length to be an exact multiple of the `char` pointer size. `sizeof(char*)` is 4 on 32-bit machines and 8 on 64-bit machines.

Additional resources

- A forum dedicated to the `MEMORY` storage engine is available at <http://forums.mysql.com/list.php?92>.

13.8. The `EXAMPLE` Storage Engine

The `EXAMPLE` storage engine is a stub engine that does nothing. Its purpose is to serve as an example in the MySQL source code that illustrates how to begin writing new storage engines. As such, it is primarily of interest to developers.

To enable the `EXAMPLE` storage engine if you build MySQL from source, invoke `configure` with the `-with-example-storage-engine` option.

To examine the source for the `EXAMPLE` engine, look in the `storage/example` directory of a MySQL source distribution.

When you create an `EXAMPLE` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. No other files are created. No data can be stored into the table. Retrievals return an empty result.

```
mysql> CREATE TABLE test (i INT) ENGINE = EXAMPLE;
Query OK, 0 rows affected (0.78 sec)

mysql> INSERT INTO test VALUES(1),(2),(3);
ERROR 1031 (HY000): Table storage engine for 'test' doesn't »
have this option

mysql> SELECT * FROM test;
Empty set (0.31 sec)
```

The **EXAMPLE** storage engine does not support indexing.

13.9. The **FEDERATED** Storage Engine

The **FEDERATED** storage engine enables data to be accessed from a remote MySQL database on a local server without using replication or cluster technology. When using a **FEDERATED** table, queries on the local server are automatically executed on the remote (federated) tables. No data is stored on the local tables.

To enable the **FEDERATED** storage engine if you build MySQL from source, invoke **configure** with the **-with-federated-storage-engine** option.

To examine the source for the **FEDERATED** engine, look in the **sql** directory of a MySQL source distribution.

MySQL Enterprise

MySQL Enterprise subscribers will find MySQL Knowledge Base articles about the **FEDERATED** storage engine at **FEDERATED Storage Engine**. Access to the Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information see <http://www.mysql.com/products/enterprise/advisors.html>.

13.9.1. **FEDERATED** Storage Engine Overview

When you create a table using one of the standard storage engines (such as **MyISAM**, **CSV** or **InnoDB**, the table consists of the table definition and the associated data. When you create a **FEDERATED** table the table definition is the same, but the physical storage of the data is handled on a remote server.

A **FEDERATED** table consists of two elements:

- A *remote server* with a database table, which in turn consists of the table definition (stored in the **.frm** file) and the associated table. The table type of the remote table may be any type supported by the remote **mysqld** server, including **MyISAM** or **InnoDB**.
- A *local server* with a database table, where the table definition matches that of the corresponding table on the remote server. The table definition is stored within the **.frm** file. However, there is no data file on the local server. Instead, the table definition includes a connection string that points to the remote table.

When executing queries and statements on a **FEDERATED** table on the local server, the operations that would normally insert, update or delete information from a local data file are instead sent to the remote server for execution, where they update the data file on the remote server or return matching rows from the remote server.

The basic structure of a **FEDERATED** table set up is shown in **Figure 13.2, “FEDERATED table structure”**.

Figure 13.2. **FEDERATED table structure**

When a client issues a SQL statement that refers to a **FEDERATED** table, the flow of information between the local server (where the SQL statement is executed) and the remote server (where the data is physically stored) is as follows:

1. The storage engine looks through each column that the **FEDERATED** table has and constructs an appropriate SQL statement that refers to the remote table.
2. The statement is sent to the remote server using the MySQL client API.
3. The remote server processes the statement and the local server retrieves any result that the statement produces (an affected-rows count or a result set).
4. If the statement produces a result set, each column is converted to internal storage engine format that the **FEDERATED** engine expects and can use to display the result to the client that issued the original statement.

The local server communicates with the remote server using MySQL client C API functions. It invokes `mysql_real_query()` to send the statement. To read a result set, it uses `mysql_store_result()` and fetches rows one at a time using `mysql_fetch_row()`.

13.9.2. How to create **FEDERATED** Tables

To create a **FEDERATED** table you should follow these steps:

1. Create the table on the remote server. Alternatively, make a note of the table definition of an existing table, perhaps using the `SHOW CREATE TABLE` statement.
2. Create the table on the local server with an identical table definition, but adding the connection information that links the local table to the remote table.

For example, you could create the following table on the remote server:

```
CREATE TABLE test_table (
  id      INT(20) NOT NULL AUTO_INCREMENT,
  name    VARCHAR(32) NOT NULL DEFAULT '',
  other   INT(20) NOT NULL DEFAULT '0',
```

```

PRIMARY KEY (id),
INDEX name (name),
INDEX other_key (other)
)
ENGINE=MyISAM
DEFAULT CHARSET=latin1;

```

To create the local table that will be federated to the remote table, there are two options available. You can either create the local table and specify the connection string (containing the server name, login, password) to be used to connect to the remote table using the [CONNECTION](#), or you can use an existing connection that you have previously created using the [CREATE SERVER](#) statement.

Note

When you create the local table is *must* have an identical definition to the remote table.

13.9.2.1. Creating a **FEDERATED** Table Using **CONNECTION**

To use the first method, you must specify the [CONNECTION](#) string after the engine type in a [CREATE TABLE](#) statement. For example:

```

CREATE TABLE federated_table (
  id      INT(20) NOT NULL AUTO_INCREMENT,
  name    VARCHAR(32) NOT NULL DEFAULT '',
  other   INT(20) NOT NULL DEFAULT '0',
  PRIMARY KEY (id),
  INDEX name (name),
  INDEX other_key (other)
)
ENGINE=FEDERATED
DEFAULT CHARSET=latin1
CONNECTION='mysql://fed_user@remote_host:9306/federated/test_table';

```

Note

[CONNECTION](#) replaces the [COMMENT](#) used in some previous versions of MySQL.

The [CONNECTION](#) string contains the information required to connect to the remote server containing the table that will be used to physically store the data. The connection string specifies the server name, login credentials, port number and database/table information. In the example, the remote table is on the server [remote_host](#), using port 9306. The name and port number should match the host-name (or IP address) and port number of the remote MySQL server instance you want to use as your remote table.

The format the connection string is as follows:

```

scheme://user_name[:password]@host_name[:port_num]/db_name/tbl_name

```

Where:

- [scheme](#) — is a recognized connection protocol. Only [mysql](#) is supported as the [scheme](#) value at this point.
- [user_name](#) — the user name for the connection. This user must have been created on the remote server, and must have suitable privileges to perform the required actions ([SELECT](#), [INSERT](#), [UPDATE](#) etc.) on the remote table.
- [password](#) — (optional) the corresponding password for [username](#).
- [host_name](#) — the hostname or IP address of the remote server.
- [port_num](#) — (optional) the port number for the remote server. The default is 3306.
- [db_name](#) — the name of the database holding the remote table.
- [table_name](#) — the name of the remote table. The name of the local and the remote table do not have to match.

Sample connection strings:

```

CONNECTION='mysql://username:password@hostname:port/database/tablename'
CONNECTION='mysql://username@hostname/database/tablename'
CONNECTION='mysql://username:password@hostname/database/tablename'

```

13.9.2.2. Creating a **FEDERATED** Table Using **CREATE SERVER**

If you are creating a number of **FEDERATED** tables on the same server, or if you want to simplify the process of creating **FEDERATED** tables, then you can use the **CREATE SERVER** statement to define the server connection parameters, just as you would with the **CONNECTION** string.

The format of the **CREATE SERVER** statement is:

```
CREATE SERVER
  server_name
  FOREIGN DATA WRAPPER wrapper_name
  OPTIONS (option ...)
```

The `server_name` is used as the connection string when creating a new **FEDERATED** table.

For example, to create a server connection identical to the **CONNECTION** string:

```
CONNECTION='mysql://root@remote_host:9306/federated/test_table';
```

You would use the following statement:

```
CREATE SERVER fedlink
  FOREIGN DATA WRAPPER mysql
  OPTIONS (USER 'fed_user', HOST 'remote_host', PORT 9306, DATABASE 'federated');
```

To create a **FEDERATED** table that uses this connection, you still use the **CONNECTION** keyword, but specify the name you used in the **CREATE SERVER** statement.

```
CREATE TABLE test_table (
  id      INT(20) NOT NULL AUTO_INCREMENT,
  name    VARCHAR(32) NOT NULL DEFAULT '',
  other   INT(20) NOT NULL DEFAULT '0',
  PRIMARY KEY (id),
  INDEX name (name),
  INDEX other_key (other)
)
ENGINE=FEDERATED
DEFAULT CHARSET=latin1
CONNECTION='fedlink.test_table';
```

The connection name in this example contains the name of the connection (`fedlink`) and the name of the table (`test_table`) to link to, separated by a period. If you do not explicitly specify a table name in this manner, then the table name of the local table is used instead.

For more information on **CREATE SERVER**, see [Section 12.1.9, “CREATE SERVER Syntax”](#).

The **CREATE SERVER** statement accepts the same arguments as the **CONNECTION** string. The **CREATE SERVER** statement updates the rows in the `mysql.servers` table. See the table for information on the parameters when using the connection string, options in the **CREATE SERVER** statement, and the columns in the `mysql.servers` table. For reference, the format of the **CONNECTION** string is as follows:

```
scheme://user_name[:password]@host_name[:port_num]/db_name/tbl_name
```

Description	CONNECTION string	CREATE SERVER option	<code>mysql.servers</code> column
Connection scheme	<code>scheme</code>	<code>wrapper_name</code>	<code>Wrapper</code>
Remote user	<code>user_name</code>	<code>USER</code>	<code>Username</code>
Remote password	<code>password</code>	<code>PASSWORD</code>	<code>Password</code>
Remote host	<code>host_name</code>	<code>HOST</code>	<code>Host</code>
Remote port	<code>port_num</code>	<code>PORT</code>	<code>Port</code>
Remote database	<code>db_name</code>	<code>DATABASE</code>	<code>Db</code>

13.9.3. **FEDERATED** Storage Engine Notes and Tips

You should be aware of the following points when using the **FEDERATED** storage engine:

- **FEDERATED** tables may be replicated to other slaves, but you must ensure that the slave servers are able to use the user/password combination that is defined in the **CONNECTION** (or the row in the `mysql.servers` table) to connect to the remote server.

The following items indicate features that the **FEDERATED** storage engine does and does not support:

- The remote server must be a MySQL server. Support by **FEDERATED** for other database engines may be added in the future.
- The remote table that a **FEDERATED** table points to *must* exist before you try to access the table through the **FEDERATED** table.
- It is possible for one **FEDERATED** table to point to another, but you must be careful not to create a loop.
- A **FEDERATED** table does not support indexes per se. Because access to the table is handled remotely, it is the remote table that supports the indexes. Care should be taken when creating a **FEDERATED** table since the index definition from an equivalent **MyISAM** or other table may not be supported. For example, creating a **FEDERATED** table with an index prefix on **VARCHAR**, **TEXT** or **BLOB** columns will fail. The following definition in **MyISAM** is valid:

```
CREATE TABLE `T1` (`A` VARCHAR(100), UNIQUE KEY(`A` (30))) ENGINE=MYISAM;
```

The key prefix in this example is incompatible with the **FEDERATED** engine, and the equivalent statement will fail:

```
CREATE TABLE `T1` (`A` VARCHAR(100), UNIQUE KEY(`A` (30))) ENGINE=FEDERATED
CONNECTION='MYSQL://127.0.0.1:3306/TEST/T1';
```

If possible, you should try to separate the column and index definition when creating tables on both the remote server and the local server to avoid these index issues.

- Internally, implementation uses **SELECT**, **INSERT**, **UPDATE**, and **DELETE**, but not **HANDLER**.
- The **FEDERATED** storage engine supports **SELECT**, **INSERT**, **UPDATE**, **DELETE**, **TRUNCATE**, and indexes. It does not support **ALTER TABLE**, or any Data Definition Language statements other than **DROP TABLE**. The current implementation does not use prepared statements.
- **FEDERATED** accepts **INSERT ... ON DUPLICATE KEY UPDATE** statements, but if a duplicate-key violation occurs, the statement fails with an error.
- Performance on a **FEDERATED** table when performing bulk inserts (for example, on a **INSERT INTO ... SELECT ...** statement) is slower than with other table types because each selected row is treated as an individual **INSERT** statement on the **FEDERATED** table.
- Transactions are not supported.
- Before MySQL 5.1.21, for a multiple-row insert into a **FEDERATED** table that refers to a remote transactional table, if the insert failed for a row due to constraint failure, the remote table would contain a partial commit (the rows preceding the failed one) instead of rolling back the statement completely. This occurred because the rows were treated as individual inserts.

As of MySQL 5.1.21, **FEDERATED** performs bulk-insert handling such that multiple rows are sent to the remote table in a batch. This provides a performance improvement and enables the remote table to perform improvement. Also, if the remote table is transactional, it enables the remote storage engine to perform statement rollback properly should an error occur. This capability has the following limitations:

- The size of the insert cannot exceed the maximum packet size between servers. If the insert exceeds this size, it is broken into multiple packets and the rollback problem can occur.
- Bulk-insert handling does not occur for **INSERT ... ON DUPLICATE KEY UPDATE**.
- There is no way for the **FEDERATED** engine to know if the remote table has changed. The reason for this is that this table must work like a data file that would never be written to by anything other than the database system. The integrity of the data in the local table could be breached if there was any change to the remote database.
- When using a **CONNECTION** string, you cannot use an '@' character in the password. You can get round this limitation by using the

`CREATE SERVER` statement to create a server connection.

- The `INSERT_ID` and `TIMESTAMP` options are not propagated to the data provider.
- Any `DROP TABLE` statement issued against a `FEDERATED` table will drop only the local table, not the remote table.
- `FEDERATED` tables do not work with the query cache.
- User-defined partitioning is not supported for `FEDERATED` tables. Beginning with MySQL 5.1.15, it is no longer possible to create such tables at all.

Some of these limitations may be lifted in future versions of the `FEDERATED` handler.

13.9.4. `FEDERATED` Storage Engine Resources

The following additional resources are available for the `FEDERATED` storage engine:

- A forum dedicated to the `FEDERATED` storage engine is available at <http://forums.mysql.com/list.php?105>.

13.10. The `ARCHIVE` Storage Engine

The `ARCHIVE` storage engine is used for storing large amounts of data without indexes in a very small footprint.

The `ARCHIVE` storage engine is included in MySQL binary distributions. To enable this storage engine if you build MySQL from source, invoke `configure` with the `--with-archive-storage-engine` option.

To examine the source for the `ARCHIVE` engine, look in the `storage/archive` directory of a MySQL source distribution.

You can check whether the `ARCHIVE` storage engine is available with this statement:

```
mysql> SHOW VARIABLES LIKE 'have_archive';
```

When you create an `ARCHIVE` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. The storage engine creates other files, all having names beginning with the table name. The data and metadata files have extensions of `.ARZ` and `.ARM`, respectively. An `.ARN` file may appear during optimization operations.

The `ARCHIVE` engine supports `INSERT` and `SELECT`, but not `DELETE`, `REPLACE`, or `UPDATE`. It does support `ORDER BY` operations, `BLOB` columns, and basically all but spatial data types (see [Section 18.4.1, “MySQL Spatial Data Types”](#)). The `ARCHIVE` engine uses row-level locking.

As of MySQL 5.1.6, the `ARCHIVE` engine supports the `AUTO_INCREMENT` column attribute. The `AUTO_INCREMENT` columns can have either a unique or non-unique index. Attempting to create an index on any other column results in an error. The `ARCHIVE` engine also supports the `AUTO_INCREMENT` table option in `CREATE TABLE` and `ALTER TABLE` statements to specify the initial sequence value for a new table or reset the sequence value for an existing table, respectively.

As of MySQL 5.1.6, the `ARCHIVE` engine ignores `BLOB` columns if they are not requested and scans past them while reading. Formerly, the following two statements had the same cost, but as of 5.1.6, the second is much more efficient than the first:

```
SELECT a, b, blob_col FROM archive_table;  
SELECT a, b FROM archive_table;
```

Storage: Rows are compressed as they are inserted. The `ARCHIVE` engine uses `zlib` lossless data compression (see <http://www.zlib.net/>). You can use `OPTIMIZE TABLE` to analyze the table and pack it into a smaller format (for a reason to use `OPTIMIZE TABLE`, see later in this section). The engine also supports `CHECK TABLE`. There are several types of insertions that are used:

- An `INSERT` statement just pushes rows into a compression buffer, and that buffer flushes as necessary. The insertion into the buffer is protected by a lock. A `SELECT` forces a flush to occur, unless the only insertions that have come in were `INSERT DELAYED` (those flush as necessary). See [Section 12.2.4.2, “INSERT DELAYED Syntax”](#).

- A bulk insert is visible only after it completes, unless other inserts occur at the same time, in which case it can be seen partially. A `SELECT` never causes a flush of a bulk insert unless a normal insert occurs while it is loading.

Retrieval: On retrieval, rows are uncompressed on demand; there is no row cache. A `SELECT` operation performs a complete table scan: When a `SELECT` occurs, it finds out how many rows are currently available and reads that number of rows. `SELECT` is performed as a consistent read. Note that lots of `SELECT` statements during insertion can deteriorate the compression, unless only bulk or delayed inserts are used. To achieve better compression, you can use `OPTIMIZE TABLE` or `REPAIR TABLE`. The number of rows in `ARCHIVE` tables reported by `SHOW TABLE STATUS` is always accurate. See [Section 12.5.2.5, “OPTIMIZE TABLE Syntax”](#), [Section 12.5.2.6, “REPAIR TABLE Syntax”](#), and [Section 12.5.4.28, “SHOW TABLE STATUS Syntax”](#).

Additional resources

- A forum dedicated to the `ARCHIVE` storage engine is available at <http://forums.mysql.com/list.php?112>.

13.11. The CSV Storage Engine

The `CSV` storage engine stores data in text files using comma-separated values format.

To enable the `CSV` storage engine if you build MySQL from source, invoke `configure` with the `-with-csv-storage-engine` option.

To examine the source for the `CSV` engine, look in the `storage/csv` directory of a MySQL source distribution.

When you create a `CSV` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. The storage engine also creates a data file. Its name begins with the table name and has a `.CSV` extension. The data file is a plain text file. When you store data into the table, the storage engine saves it into the data file in comma-separated values format.

```
mysql> CREATE TABLE test(i INT, c CHAR(10)) ENGINE = CSV;
Query OK, 0 rows affected (0.12 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM test;
+----+-----+
| i  | c      |
+----+-----+
| 1  | record one |
| 2  | record two |
+----+-----+
2 rows in set (0.00 sec)
```

Starting with MySQL 5.1.9, creating a CSV table also creates a corresponding Meta-file that stores the state of the table and the number of rows that exist in the table. The name of this file is the same as the name of the table with the extension `CSM`.

If you examine the `test.CSV` file in the database directory created by executing the preceding statements, its contents should look like this:

```
"1","record one"
"2","record two"
```

This format can be read, and even written, by spreadsheet applications such as Microsoft Excel or StarOffice Calc.

13.11.1. Repairing and Checking CSV Tables

Functionality introduced in version 5.1.9

The `CSV` storage engines supports the `CHECK` and `REPAIR` commands to verify and if possible repair a damaged `CSV` table.

When running the `CHECK` command, the `CSV` file will be checked for validity by looking for the correct field separators, escaped fields (matching quotes and/or missing quotes), the correct number of fields compared to the table definition and the existence of a corresponding `CSV` metafile. The first invalid row discovered will report an error. Checking a valid table produces output like that shown below:

```
mysql> check table csvtest;
```

Table	Op	Msg_type	Msg_text
test.csvtest	check	status	OK

```
1 row in set (0.00 sec)
```

A check on a corrupted table returns a fault:

```
mysql> check table csvtest;
```

Table	Op	Msg_type	Msg_text
test.csvtest	check	error	Corrupt

```
1 row in set (0.01 sec)
```

If the check fails, the table is marked as crashed (corrupt). Once a table has been marked as corrupt, it is automatically repaired when you next run **CHECK** or execute a **SELECT** statement. The corresponding corrupt status and new status will be displayed when running **CHECK**:

```
mysql> check table csvtest;
```

Table	Op	Msg_type	Msg_text
test.csvtest	check	warning	Table is marked as crashed
test.csvtest	check	status	OK

```
2 rows in set (0.08 sec)
```

To repair a table you can use **REPAIR**, this copies as many valid rows from the existing CSV data as possible, and then replaces the existing CSV file with the recovered rows. Any rows beyond the corrupted data are lost.

```
mysql> repair table csvtest;
```

Table	Op	Msg_type	Msg_text
test.csvtest	repair	status	OK

```
1 row in set (0.02 sec)
```

Warning

Note that during repair, only the rows from the CSV file up to the first damaged row are copied to the new table. All other rows from the first damaged row to the end of the table are removed, even valid rows.

13.11.2. CSV Limitations

Important

The **CSV** storage engine does not support indexing.

Partitioning is not supported for tables using the **CSV** storage engine. Beginning with MySQL 5.1.12, it is no longer possible to create partitioned **CSV** tables. (See [Bug#19307](#))

13.12. The **BLACKHOLE** Storage Engine

The **BLACKHOLE** storage engine acts as a “black hole” that accepts data but throws it away and does not store it. Retrievals always return an empty result:

```
mysql> CREATE TABLE test(i INT, c CHAR(10)) ENGINE = BLACKHOLE;
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM test;
Empty set (0.00 sec)
```

To enable the **BLACKHOLE** storage engine if you build MySQL from source, invoke `configure` with the `-with-blackhole-storage-engine` option.

To examine the source for the **BLACKHOLE** engine, look in the `sql` directory of a MySQL source distribution.

When you create a **BLACKHOLE** table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. There are no other files associated with the table.

The **BLACKHOLE** storage engine supports all kinds of indexes. That is, you can include index declarations in the table definition.

You can check whether the **BLACKHOLE** storage engine is available with this statement:

```
mysql> SHOW VARIABLES LIKE 'have_blackhole_engine';
```

Inserts into a **BLACKHOLE** table do not store any data, but if the binary log is enabled, the SQL statements are logged (and replicated to slave servers). This can be useful as a repeater or filter mechanism. For example, suppose that your application requires slave-side filtering rules, but transferring all binary log data to the slave first results in too much traffic. In such a case, it is possible to set up on the master host a “dummy” slave process whose default storage engine is **BLACKHOLE**, depicted as follows:

The master writes to its binary log. The “dummy” `mysqld` process acts as a slave, applying the desired combination of `replicate-do-*` and `replicate-ignore-*` rules, and writes a new, filtered binary log of its own. (See [Section 15.1.3, “Replication Options and Variables”](#).) This filtered log is provided to the slave.

The dummy process does not actually store any data, so there is little processing overhead incurred by running the additional `mysqld` process on the replication master host. This type of setup can be repeated with additional replication slaves.

INSERT triggers for **BLACKHOLE** tables work as expected. However, because the **BLACKHOLE** table does not actually store any data, **UPDATE** and **DELETE** triggers are not activated: The **FOR EACH ROW** clause in the trigger definition does not apply because there are no rows.

Other possible uses for the **BLACKHOLE** storage engine include:

- Verification of dump file syntax.
- Measurement of the overhead from binary logging, by comparing performance using **BLACKHOLE** with and without binary logging enabled.
- **BLACKHOLE** is essentially a “no-op” storage engine, so it could be used for finding performance bottlenecks not related to the storage engine itself.

The **BLACKHOLE** storage engine does not support **INSERT DELAYED**, **LOCK TABLES**, or **UNLOCK TABLES** statements prior to MySQL 5.1.19.

As of MySQL 5.1.4, the **BLACKHOLE** engine is transaction-aware, in the sense that committed transactions are written to the binary log and rolled-back transactions are not.

Chapter 14. High Availability, Scalability, and DRBD

When using MySQL you may need to ensure the availability or scalability of your MySQL installation. Availability refers to the ability to cope with, and if necessary recover from, failures on the host, including failures of MySQL, the operating system, or the hardware. Scalability refers to the ability to spread the load of your application queries across multiple MySQL servers. As your application and usage increases, you may need to spread the queries for the application across multiple servers to improve response times.

There are a number of solutions available for solving issues of availability and scalability. The two primary solutions supported by MySQL are MySQL Replication and MySQL Cluster. Further options are available using third-party solutions such as DRBD (Distributed Replicated Block Device) and Heartbeat, and more complex scenarios can be solved through a combination of these technologies. These tools work in different ways:

- *MySQL Replication* enables statements and data from one MySQL server instance to be replicated to another MySQL server instance. Without using more complex setups, data can only be replicated from a single master server to any number of slaves. The replication is asynchronous, so the synchronization does not take place in real time, and there is no guarantee that data from the master will have been replicated to the slaves.
 - **Advantages**
 - MySQL Replication is available on all platforms supported by MySQL, and since it isn't operating system-specific it can operate across different platforms.
 - Replication is asynchronous and can be stopped and restarted at any time, making it suitable for replicating over slower links, partial links and even across geographical boundaries.
 - Data can be replicated from one master to any number of slaves, making replication suitable in environments with heavy reads, but light writes (for example, many web applications), by spreading the load across multiple slaves.
 - **Disadvantages**
 - Data can only be written to the master. In advanced configurations, though, you can set up a multiple-master configuration where the data is replicated around a ring configuration.
 - There is no guarantee that data on master and slaves will be consistent at a given point in time. Because replication is asynchronous there may be a small delay between data being written to the master and it being available on the slaves. This can cause problems in applications where a write to the master must be available for a read on the slaves (for example a web application).
 - **Recommended uses**
 - Scale-out solutions that require a large number of reads but fewer writes (for example, web serving).
 - Logging/data analysis of live data. By replicating live data to a slave you can perform queries on the slave without affecting the operation of the master.
 - Online backup (availability), where you need an active copy of the data available. You need to combine this with other tools, such as custom scripts or Heartbeat. However, because of the asynchronous architecture, the data may be incomplete.
 - Offline backup. You can use replication to keep a copy of the data. By replicating the data to a slave, you take the slave down and get a reliable snapshot of the data (without MySQL running), then restart MySQL and replication to catch up. The master (and any other slaves) can be kept running during this period.

For information on setting up and configuring replication, see [Chapter 15, Replication](#).

- *MySQL Cluster* is a synchronous solution that enables multiple MySQL instances to share database information. Unlike replication, data in a cluster can be read from or written to any node within the cluster, and information will be distributed to the other nodes.
 - **Advantages**
 - Offers multiple read and write nodes for data storage.
 - Provides automatic failover between nodes. Only transaction information for the active node being used is lost in the event of a failure.
 - Data on nodes is instantaneously distributed to the other data nodes.

- **Disadvantages**

- Available on a limited range of platforms.
- Nodes within a cluster should be connected via a LAN; geographically separate nodes are not supported. However, you can replicate from one cluster to another using MySQL Replication, although the replication in this case is still asynchronous.

- **Recommended uses**

- Applications that need very high availability, such as telecoms and banking.
- Applications that require an equal or higher number of writes compared to reads.

For information on MySQL Cluster, see [Chapter 16, MySQL Cluster](#).

- *DRBD (Distributed Replicated Block Device)* is a third-party solution from Linbit supported only on Linux. DRBD creates a virtual block device (which is associated with an underlying physical block device) that can be replicated from the primary server to a secondary server. You create a filesystem on the virtual block device, and this information is then replicated, at the block level, to the secondary server.

Because the block device, not the data you are storing on it, is being replicated the validity of the information is more reliable than with data-only replication solutions. DRBD can also ensure data integrity by only returning from a write operation on the primary server when the data has been written to the underlying physical block device on both the primary and secondary servers.

- **Advantages**

- Provides high availability and data integrity across two servers in the event of hardware or system failure.
- Ensures data integrity by enforcing write consistency on the primary and secondary nodes.

- **Disadvantages**

- Only provides a method for duplicating data across the nodes. Secondary nodes cannot use the DRBD device while data is being replicated, and so the MySQL on the secondary node cannot be simultaneously active.
- Cannot provide scalability, since secondary nodes don't have access to the secondary data.

- **Recommended uses**

- High availability situations where concurrent access to the data is not required, but instant access to the active data in the event of a system or hardware failure is required.

For information on configuring DRBD and configuring MySQL for use with a DRBD device, see [Section 14.1, “Using MySQL with DRBD for High Availability”](#).

- *Heartbeat* is a third party software solution for Linux. It is not a data replication or synchronization solution, but a solution for monitoring servers and switching active MySQL servers automatically in the event of failure. Heartbeat needs to be combined with MySQL Replication or DRBD to provide automatic failover.

The information and suitability of the various technologies and different scenarios is summarized in the table below.

Requirements	MySQL Replication	MySQL Replication + Heartbeat	MySQL Heartbeat + DRBD	MySQL Cluster
Availability				
Automated IP failover	No	Yes	Yes	No
Automated database failover	No	No	Yes	Yes
Typical failover time	User/script-dependent	Varies	< 30 seconds	< 3 seconds
Automatic resynchronization of data	No	No	Yes	Yes
Geographic redundancy	Yes	Yes	Yes, when combined with	Yes, when combined with

Requirements	MySQL Replication	MySQL Replication + Heartbeat	MySQL Heartbeat + DRBD	MySQL Cluster
support			MySQL Replication	MySQL Replication
Scalability				
Built-in load balancing	No	No	No	Yes
Supports Read-intensive applications	Yes	Yes	Yes, when combined with MySQL Replication	Yes
Supports Write-intensive applications	No	No	Yes	Yes
Maximum number of nodes per group	One master, multiple slaves	One master, multiple slaves	One active (primary), multiple passive (secondary) nodes	255
Maximum number of slaves	Unlimited (reads only)	Unlimited (reads only)	Unlimited (reads only)	Unlimited (reads only)

14.1. Using MySQL with DRBD for High Availability

The Distributed Replicated Block Device (DRBD) is a Linux Kernel module that supports a distributed storage system. You can use DRBD to share block devices between Linux servers and, in turn, share filesystems and data.

DRBD implements a block device which can be used for storage and which is replicated from a primary server to one or more secondary servers. The distributed block device is handled by the DRBD service. Writes to the DRBD block device are distributed among the servers. Each DRBD service writes the information from the DRBD block device to a local physical block device (hard disk).

On the primary, for example, the data writes are written both to the underlying physical block device and distributed to the secondary DRBD services. On the secondary, the writes received through DRBD and written to the local physical block device. On both the primary and the secondary, reads from the DRBD block device are handled by the underlying physical block device. The information is shared between the primary DRBD server and the secondary DRBD server synchronously and at a block level, and this means that DRBD can be used in high-availability solutions where you need failover support.

When used with MySQL, DRBD can be used to ensure availability in the event of a failure. MySQL is configured to store information on the DRBD block device, with one server acting as the primary and a second machine available to operate as an immediate replacement in the event of a failure.

For automatic failover support you can combine DRBD with the Linux Heartbeat project, which will manage the interfaces on the two

servers and automatically configure the secondary (passive) server to replace the primary (active) server in the event of a failure. You can also combine DRBD with MySQL Replication to provide both failover and scalability within your MySQL environment.

In this section we will cover the basics of setting up a DRBD based solution, how to combine this with Linux Heartbeat and at solutions and topologies that make combine DRBD and MySQL Replication.

For information on how to configure DRBD and MySQL, including Heartbeat support, see [Section 14.1.1, “Configuring a MySQL and DRBD Environment”](#).

An FAQ for using DRBD and MySQL is available. See [Section A.14, “MySQL 5.1 FAQ — MySQL, DRBD, and Heartbeat”](#).

Note

Because DRBD is a Linux Kernel module it is currently not supported on platforms other than Linux.

14.1.1. Configuring a MySQL and DRBD Environment

To set up DRBD, MySQL and Heartbeat you need to follow a number of steps that affect the operating system, DRBD and your MySQL installation.

Before starting the installation process, you should be aware of the following information, terms and requirements on using DRBD:

- DRBD is a solution for enabling high-availability, and therefore you need to ensure that the two machines within your DRBD setup are as identically configured as possible so that the secondary machine can act as a direct replacement for the primary machine in the event of system failure.
- DRBD works through two (or more) servers, each called a *node*
- The node that contains the primary data, has read/write access to the data, and in an HA environment is the currently active node is called the *primary*.
- The server to which the data is replicated is designated as *secondary*.
- A collection of nodes that are sharing information are referred to as a *DRBD cluster*.
- For DRBD to operate you must have a block device on which the information can be stored on *each* DRBD node. The *lower level* block device can be a physical disk partition, a partition from a volume group or RAID device or any other block device.

Typically you use a spare partition on which the physical data will be stored . On the primary node, this disk will hold the raw data that you want replicated. On the secondary nodes, the disk will hold the data replicated to the secondary server by the DRBD service. Ideally, the size of the partition on the two DRBD servers should be identical, but this is not necessary as long as there is enough space to hold the data that you want distributed between the two servers.

- For the distribution of data to work, DRBD is used to create a logical block device that uses the lower level block device for the actual storage of information. To store information on the distributed device, a filesystem is created on the DRBD logical block device.
- When used with MySQL, once the filesystem has been created, you move the MySQL data directory (including InnoDB data files and binary logs) to the new filesystem.
- When you set up the secondary DRBD server, you set up the physical block device and the DRBD logical block device that will store the data. The block device data is then copied from the primary to the secondary server.

The overview for the installation and configuration sequence is as follows:

1. First you need to set up your operating system and environment. This includes setting the correct hostname, updating the system and preparing the available packages and software required by DRBD, and configuring a physical block device to be used with the DRBD block device. See [Section 14.1.1.1, “Setting up the Operating System”](#).
2. Installing DRBD requires installing or compiling the DRBD source code and then configuring the DRBD service to set up the block devices that will be shared. See [Section 14.1.1.2, “Installing and Configuring DRBD”](#).
3. Once DRBD has been configured, you must alter the configuration and storage location of the MySQL data. See [Section 14.1.1.3,](#)

“Configuring MySQL for DRBD”.

14.1.1.1. Setting up the Operating System

To set your Linux environment for using DRBD there are a number of system configuration steps that you must follow.

- Make sure that the primary and secondary DRBD servers have the correct hostname, and that the hostnames are unique. You can verify this by using the `uname` command:

```
$ uname -n  
drbd-master
```

If the hostname is not set correctly then edit the appropriate file (usually `/etc/sysconfig/network` or `/etc/conf.d/hostname`) and set the name correctly.

- Each DRBD node must have a unique IP address. Make sure that the IP address information is set correctly within the network configuration and that the hostname and IP address has been set correctly within the `/etc/hosts` file.
- Although you can rely on the DNS or NIS system for host resolving, in the event of a major network failure these services may not be available. If possible, add the IP address and hostname of each DRBD node into the `/etc/hosts` file for each machine. This will ensure that the node information can always be determined even if the DNS/NIS servers are unavailable.
- As a general rule, the faster your network connection the better. Because the block device data is exchanged over the network, everything that will be written to the local disk on the DRBD primary will also be written to the network for distribution to the DRBD secondary.
- You must have a spare disk or disk partition that you can use as the physical storage location for the DRBD data that will be replicated. You do not have to have a complete disk available, a partition on an existing disk is acceptable.

If the disk is unpartitioned, partition the disk using `fdisk`. Do not create a filesystem on the new partition.

Remember that you must have a physical disk available for the storage of the replicated information on each DRBD node. Ideally the partitions that will be used on each node should be of an identical size, although this is not strictly necessary. Do, however, ensure that the physical partition on the DRBD secondary is at least as big as the partitions on the DRBD primary node.

- If possible, upgrade your system to the latest available Linux kernel for your distribution. Once the kernel has been installed, you must reboot to make the kernel active. To use DRBD you will also need to install the relevant kernel development and header files that are required for building kernel modules. Platform specification information for this is available later in this section.

Before you compile or install DRBD, you must make

- Kernel header files
- Kernel source files
- GCC Compiler
- `glib 2`
- `flex`
- `bison`

Additionally, if you want to support secure communication between your DRBD nodes then the following items will be required:

- OpenSSL
- GNU TLS
- GNU Crypt

Here are some operating system specific tips for setting up your installation:

- **Tips for Red Hat (including CentOS and Fedora):**

Use [up2date](#) or [yum](#) to update and install the latest kernel and kernel header files:

```
# up2date kernel-smp-devel kernel-smp
```

Reboot. If you are going to build DRBD from source, then update your system with the required development packages

```
# up2date glib-devel openssl-devel libgcrypt-devel glib2-devel \
pkgconfig ncurses-devel rpm-build rpm-devel redhat-rpm-config gcc \
gcc-c++ bison flex gnutls-devel lm_sensors-devel net-snmp-devel \
python-devel bzip2-devel libselinux-devel perl-DBI
```

If you are going to use the pre-built DRBD RPMs:

```
# up2date gnutls lm_sensors net-snmp ncurses libgcrypt glib2 openssl glib
```

- **Tips for Debian, Ubuntu, Kubuntu:**

Use [apt-get](#) to install the kernel packages

```
# apt-get install linux-headers linux-image-server
```

If you are going to use the pre-built Debian packages for DRBD then you should not need any additional packages.

If you want to build DRBD from source, you will need to use the following command to install the required components:

```
# apt-get install devscripts flex bison build-essential \
dpkg-dev kernel-package debconf-utils dpatch debhelper \
libnet1-dev e2fslibs-dev libglib2.0-dev automake1.9 \
libgnutls-dev libtool libltdl3 libltdl3-dev
```

- **Tips for Gentoo:**

Gentoo is a source based Linux distribution and therefore many of the source files and components that you will need are either already installed or will be installed automatically by [emerge](#).

To install DRBD 0.8.x, you must unmask the [sys-cluster/drbd](#) build by adding the following line to [/etc/portage/package.keywords](#):

```
sys-cluster/drbd ~x86
```

If your kernel does not already have the userspace to kernelspace linker enabled, then you will need to add the following line to your kernel configuration ([/etc/kernels/kernel-config-*](#) file):

```
CONFIG_CONNECTOR=y
```

You can now [emerge](#) DRBD 0.8.x into your Gentoo installation:

```
# emerge drbd
```

14.1.1.2. Installing and Configuring DRBD

To install DRBD you can choose either the pre-built binary installation packages or you can use the source packages and build from source. If you want to build from source you must have installed the source and development packages.

If you are installing using a binary distribution then you must ensure that the kernel version number of the binary package matches your currently active kernel. You can use [uname](#) to find out this information:

```
$ uname -r
2.6.20-gentoo-r6
```

To build from the sources, download the source [tar.gz](#) package, extract the contents and then follow the instructions within the [INSTALL](#) file.

To install DRBD on Gentoo:

```
# emerge drbd
```

Note

Note that this may install an older version of the DRBD software. In this case you must install DRBD from the source tarball by hand.

Once DRBD has been configured and installed you must copy the default DRBD configuration file from [/usr/share/drbd-0.7.23/drbd.conf.bz2](#) to [/etc](#) and then uncompress it using [bunzip2](#).

Once DRBD has been built and installed, you need to edit the [/etc/drbd.conf](#) file and then run a number of commands to build the block device and setup the replication.

Although the steps below are split into those for the primary node and the secondary node, it should be noted that the configuration files for all nodes should be identical, and many of the same steps have to be repeated on each node to enable the DRBD block device.

14.1.1.2.1. Setting up a DRBD Primary Node

To set up a DRBD primary node you need to configure the DRBD service, create the first DRBD block device and then create a filesystem on the device so that you can store files and data.

The DRBD configuration file ([/etc/drbd.conf](#)) defines a number of parameters for your DRBD configuration, including the frequency of updates and block sizes, security information and the definition of the DRBD devices that you want to create.

The key elements to configure are the [on](#) sections which specify the configuration of each node.

To follow the configuration, the sequence below shows only the changes from the default [drbd.conf](#) file. Configurations within the file can be both global, and tied to specific resource (

1. Set the synchronization rate between the two nodes. You should keep this in check compared to the speed of your network connection. Gigabit Ethernet can support up to 125 MB/second, 100Mbps Ethernet slightly less than a tenth of that (12MBps). If you are using a shared network connection, rather than a dedicated, then you should gauge accordingly.

To set the synchronization rate, edit the [rate](#) setting within the [syncer](#) block:

```
syncer {  
    rate 10M;  
}
```

2. Set up some basic authentication. DRBD supports a simple password hash exchange mechanism. This helps to ensure that only those hosts with the same shared secret are able to join the DRBD node group.

```
cram-hmac-alg "sha1";  
shared-secret "shared-string";
```

3. Now you must configure the host information. Remember that you must have the node information for the primary and secondary nodes in the [drbd.conf](#) file on each host. You need to configure the following information for each node:

- [device](#) — the path of the logical block device that will be created by DRBD.
- [disk](#) — the block device that will be used to store the data.
- [address](#) — the IP address and port number of the host that will hold this DRBD device.
- [meta-disk](#) — the location where the metadata about the DRBD device will be stored. You can set this to [internal](#) and DRBD will use the physical block device to store the information, by recording the metadata within the last sections of the disk. The exact size will depend on the size of the logical block device you have created, but it may involve up to 128MB.

A sample configuration for our primary server might look like this:

```
on drbd-master {  
  device /dev/drbd0;  
  disk /dev/hdd1;  
  address 192.168.0.240:8888;  
  meta-disk internal;  
}
```

The **on** configuration block should be repeated for the secondary node (and any further) nodes:

```
on drbd-slave {  
  device /dev/drbd0;  
  disk /dev/hdd1;  
  address 192.168.0.241:8888;  
  meta-disk internal;  
}
```

The IP address of each **on** block must match the IP address of the corresponding host. Do not set this value to the IP address of the corresponding primary or secondary in each case.

4. Before starting the primary node, you should create the metadata for the devices:

```
# drbdmeta create-md all
```

5. You are now ready to start DRBD:

```
# /etc/init.d/drbd start
```

DRBD should now start and initialize, creating the DRBD devices that you have configured.

6. DRBD creates a standard block device - to make it usable, you must create a filesystem on the block device just as you would with any standard disk partition. Before you can create the filesystem, you must mark the new device as the primary device (i.e. where the data will be written and stored), and initialize the device. Because this is a destructive operation, you must specify the command line option to overwrite the raw data:

```
# drbdadm -- --overwrite-data-of-peer primary all
```

If you are using a version of DRBD earlier than 0.8.0, then you need to use a different command-line option:

```
# drbdadm -- --do-what-I-say primary all
```

Now create a filesystem using your chosen filesystem type:

```
# mkfs.ext3 /dev/drbd0
```

7. You can now mount the filesystem and if necessary copy files to the mount point:

```
# mkdir /mnt/drbd  
# mount /dev/drbd0 /mnt/drbd  
# echo "DRBD Device" >/mnt/drbd/samplefile
```

Your primary node is now ready to use. You should now configure your secondary node or nodes.

14.1.1.2.2. Setting up a DRBD Secondary Node

The configuration process for setting up a secondary node is the same as for the primary node, except that you do not have to create the filesystem on the secondary node device, as this information will automatically be transferred from the primary node.

To setup a secondary node:

1. Copy the `/etc/drbd.conf` file from your primary node to your secondary node. It should already contain all the information and configuration that you need, since you had to specify the secondary node IP address and other information for the primary node configuration.

2. Create the DRBD metadata on the underlying disk device:

```
# drbdmeta create-md all
```

3. Start DRBD:

```
# /etc/init.d/drbd start
```

Once DRBD has started, it will start the copy the data from the primary node to the secondary node. Even with an empty filesystem this will take some time, since DRBD is copying the block information from a block device, not simply copying the filesystem data.

You can monitor the progress of the copy between the primary and secondary nodes by viewing the output of [/proc/drbd](#):

```
cat /proc/drbd
version: 8.0.4 (api:86/proto:86)
SVN Revision: 2947 build by root@drbd-master, 2007-07-30 16:43:05
0: cs:SyncSource st:Primary/Secondary ds:UpToDate/Inconsistent C r---
   ns:252284 nr:0 dw:0 dr:257280 al:0 bm:15 lo:0 pe:7 ua:157 ap:0
   [==>.....] sync'ed: 12.3% (1845088/2097152)K
   finish: 0:06:06 speed: 4,972 (4,580) K/sec
   resync: used:1/31 hits:15901 misses:16 starving:0 dirty:0 changed:16
   act_log: used:0/257 hits:0 misses:0 starving:0 dirty:0 changed:0
```

14.1.1.2.3. Monitoring and Managing your DRBD device

Once the primary and secondary machines are configured and synchronized, you can get the status information about your DRBD device is to view the output from [/proc/drbd](#):

```
version: 8.0.4 (api:86/proto:86)
SVN Revision: 2947 build by root@drbd-master, 2007-07-30 16:43:05
0: cs:Connected st:Primary/Secondary ds:UpToDate/UpToDate C r---
   ns:2175704 nr:0 dw:99192 dr:2076641 al:33 bm:128 lo:0 pe:0 ua:0 ap:0
   resync: used:0/31 hits:134841 misses:135 starving:0 dirty:0 changed:135
   act_log: used:0/257 hits:24765 misses:33 starving:0 dirty:0 changed:33
```

The first line provides the version/revision and build information.

The second line starts the detailed status information for an individual resource. The individual field headings are as follows:

- cs — connection state
- st — node state (local/remote)
- ld — local data consistency
- ds — data consistency
- ns — network send
- nr — network receive
- dw — disk write
- dr — disk read
- pe — pending (waiting for ack)
- ua — unack'd (still need to send ack)
- al — access log write count

In the previous example, the information shown indicates that the nodes are connected, the local node is the primary (because it is listed first), and the local and remote data is up to date with each other. The remainder of the information is statistical data about the device, and the data exchanged that kept the information up to date.

For administration, the main command is `drbdadm`. There are a number of commands supported by this tool to control the connectivity and status of the DRBD devices.

The most common commands are those to set the primary/secondary status of the local device. You can manually set this information for a number of reasons, including when you want to check the physical status of the secondary device (since you cannot mount a DRBD device in primary mode), or when you are temporarily moving the responsibility of keeping the data in check to a different machine (for example, during an upgrade or physical move of the normal primary node). You can set state of all local device to be the primary using this command:

```
# drbdadm primary all
```

Or switch the local device to be the secondary using:

```
# drbdadm secondary all
```

To change only a single DRBD resource, specify the resource name instead of `all`.

You can temporarily disconnect the DRBD nodes:

```
# drbdadm disconnect all
```

Reconnect them using `connect`:

```
# drbdadm connect all
```

For other commands and help with `drbdadm` see the DRBD documentation.

14.1.1.2.4. Additional DRBD Configuration Options

Additional options you may want to configure:

- `protocol` — specifies the level of consistency to be used when information is written to the block device. The option is similar in principle to the `innodb_flush_log_at_trx_commit` option within MySQL. Three levels are supported:
 - `A` — data is considered written when the information reaches the TCP send buffer and the local physical disk. There is no guarantee that the data has been written to the remote server or the remote physical disk.
 - `B` — data is considered written when the data has reached the local disk and the remote node's network buffer. The data has reached the remote server, but there is no guarantee it has reached the remote servers physical disk.
 - `C` — data is considered written when the data has reached the local disk and the remote nodes physical disk.

The preferred and recommended protocol is `C`, as it is the only protocol which ensures the consistency of the local and remote physical storage.

- `on-io-error` — specifies what should happen when there is an error with the physical block device. Suitable values include `panic`, which causes the node to leave the DRBD cluster by causing a kernel panic (and which would trigger automatic failover if you were using Heartbeat); and `detach`, which switches DRBD into a diskless mode (i.e. data is not written to the lower level block device).
- `size` — if you do not want to use the entire partition space with your DRBD block device then you can specify the size of the DRBD device to be created. The size specification can include a quantifier. For example, to set the maximum size of the DRBD partition to 1GB you would use:

```
size 1G;
```

With the configuration file suitably configured and ready to use, you now need to populate the lower-level device with the metadata information, and then start the DRBD service.

14.1.1.3. Configuring MySQL for DRBD

Once you have configured DRBD and have an active DRBD device and filesystem, you can configure MySQL to use the chosen device to store the MySQL data.

When performing a new installation of MySQL, you can either select to install MySQL entirely onto the DRBD device, or just configure the data directory to be located on the new filesystem.

In either case, the files and installation must take place on the primary node, because that is the only DRBD node on which you can mount the DRBD device filesystem as read/write.

You should store the following files and information on your DRBD device:

- MySQL data files, including the binary log, and InnoDB data files.
- MySQL configuration file (`my.cnf`).

To setup MySQL to use your new DRBD device and filesystem:

1. If you are migrating an existing MySQL installation, stop MySQL:

```
$ mysqladmin shutdown
```

2. Copy the `my.cnf` onto the DRBD device. If you are not already using a configuration file, copy one of the sample configuration files from the MySQL distribution.

```
# mkdir /mnt/drbd/mysql
# cp /etc/my.cnf /mnt/drbd/mysql
```

3. Copy your MySQL data directory to the DRBD device and mounted filesystem.

```
# cp -R /var/lib/mysql /drbd/mysql/data
```

4. Edit the configuration file to reflect the change of directory by setting the value of the `datadir` option. If you have not already enabled the binary log, also set the value of the `log-bin` option.

```
datadir = /drbd/mysql/data
log-bin = mysql-bin
```

5. Create a symbolic link from `/etc/my.cnf` to the new configuration file on the DRBD device filesystem.

```
# ln -s /drbd/mysql/my.cnf /etc/my.cnf
```

6. Now start MySQL and check that the data that you copied to the DRBD device filesystem is present.

```
# /etc/init.d/mysql start
```

Your MySQL data should now be located on the filesystem running on your DRBD device. The data will be physically stored on the underlying device that you configured for the DRBD device. Meanwhile, the content of your MySQL databases will be copied to the secondary DRBD node.

Note that you cannot access the information on your secondary node, as a DRBD device working in secondary mode is not available for use.

Chapter 15. Replication

Replication enables data from one MySQL database server (called the master) to be replicated to one or more MySQL database servers (slaves). Replication is asynchronous - your replication slaves do not need to be connected permanently to receive updates from the master, which means that updates can occur over long-distance connections and even temporary solutions such as a dial-up service. Depending on the configuration, you can replicate all databases, selected databases and even selected tables within a database.

The target uses for replication in MySQL include:

- Scale-out solutions - spreading the load among multiple slaves to improve performance. In this environment, all writes and updates must take place on the master server. Reads, however, may take place on one or more slaves. This model can improve the performance of writes (since the master is dedicated to updates), while dramatically increasing read speed across an increasing number of slaves.
- Data security - because data is replicated to the slave, and the slave can pause the replication process, it is possible to run backup services on the slave without corrupting the corresponding master data.
- Analytics - live data can be created on the master, while the analysis of the information can take place on the slave without affecting the performance of the master.
- Long-distance data distribution - if a branch office would like to work with a copy of your main data, you can use replication to create a local copy of the data for their use without requiring permanent access to the master.

Replication in MySQL features support for one-way, asynchronous replication, in which one server acts as the master, while one or more other servers act as slaves. This is in contrast to the *synchronous* replication which is a characteristic of MySQL Cluster (see [Chapter 16, MySQL Cluster](#)).

There are a number of solutions available for setting up replication between two servers, but the best method to use depends on the presence of data and the engine types you are using. For more information on the available options, see [Section 15.1.1, “How to Set Up Replication”](#).

There are two core types of replication format, Statement Based Replication (SBR), which replicates entire SQL statements, and Row Based Replication (RBR), which replicates only the changed rows. You may also use a third variety, Mixed Based Replication (MBR), which is the default mode within MySQL 5.1.14 and later. For more information on the different replication formats, see [Section 15.1.2, “Replication Formats”](#).

Replication is controlled through a number of different options and variables. These control the core operation of the replication, timeouts and the databases and filters that can be applied on databases and tables. For more information on the available options, see [Section 15.1.3, “Replication Options and Variables”](#).

You can use replication to solve a number of different problems, including problems with performance, supporting the backup of different databases and for use as part of a larger solution to alleviate system failures. For information on how to address these issues, see [Section 15.2, “Replication Solutions”](#).

For notes and tips on how different data types and statements are treated during replication, including details of replication features, version compatibility, upgrades, and problems and their resolution, including an FAQ, see [Section 15.3, “Replication Notes and Tips”](#).

Detailed information on the implementation of replication, how replication works, the process and contents of the binary log, background threads and the rules used to decide how statements are recorded and replication, see [Section 15.4, “Replication Implementation”](#).

MySQL Enterprise

The MySQL Enterprise Monitor provides numerous advisors that provide immediate feedback about replication-related problems. For more information see, <http://www.mysql.com/products/enterprise/advisors.html>.

15.1. Replication Configuration

Replication between servers in MySQL works through the use of the binary logging mechanism. The MySQL instance operating as the master (the source of the database changes) writes updates and changes to the database to the binary log. The information in the binary log is stored in different logging formats according to the database changes being recorded. Slaves are configured to read the binary log from the master and to execute the events in the binary log on the slave's local database.

The Master is dumb in this scenario. Once binary logging has been enabled, all statements are recorded in the binary log. Each slave will receive a copy of the entire contents of the binary log. It is the responsibility of the slave to decide which statements in the binary log should be executed; you cannot configure the master to log only certain events. If you do not specify otherwise, all events in the master binary log are executed on the slave. If required, you can configure the slave to only process events that apply to particular databases or tables.

Slaves keep a record of the binary log file and position within the log file that they have read and processed from the master. This means that multiple slaves can be connected to the master and executing different parts of the same binary log. Because the slaves control this process, individual slaves can be connected and disconnected from the server without affecting the master's operation. Also, because each slave remembers the position within the binary log, it is possible for slaves to be disconnected, reconnect and then 'catch up' by continuing from the recorded position.

Both the master and each slave must be configured with a unique id (using the `server-id` option). In addition, the slave must be configured with information about the master host name, log file name and position within that file. These details can be controlled from within a MySQL session using the `CHANGE MASTER` statement. The details are stored within the `master.info` file.

In this section the setup and configuration required for a replication environment is described, including step-by-step instructions for creating a new replication environment. The major components of this section are:

- For a guide to setting up two or more servers for replication see [Section 15.1.1, “How to Set Up Replication”](#). This section deals with the setup of the systems and provides methods for copying data between the master and slaves.
- Events in the binary log are recorded using a number of formats. These are referred to as statement based replication (SBR) or row based replication (RBR). A third type, mixed-format replication (MIXED), uses SBR or RBR replication automatically to take advantage of the benefits of both SBR and RBR formats when appropriate. The different formats are discussed in [Section 15.1.2, “Replication Formats”](#).
- Detailed information on the different configuration options and variables that apply to replication is provided in [Section 15.1.3, “Replication Options and Variables”](#).
- Once started, the replication process should require little administration or monitoring. However, for advice on common tasks that you may want to executed, see [Section 15.1.4, “Common Replication Administration Tasks”](#).

15.1.1. How to Set Up Replication

This section describes how to set up complete replication of a MySQL server. There are a number of different methods for setting up replication, and the exact method that you use will depend on how you are setting up replication, and whether you already have data within your master database.

There are some generic tasks which may be required for all replication setups:

- You may want to create a separate user that will be used by your slaves to authenticate with the master to read the binary log for replication. The step is optional. See [Section 15.1.1.1, “Creating a User For Replication”](#).
- You must configure the master to support the binary log and configure a unique ID. See [Section 15.1.1.2, “Setting the Replication Master Configuration”](#).
- You must configure a unique ID for each slave that you want to connect to the Master. See [Section 15.1.1.3, “Setting the Replication Slave Configuration”](#).
- Before starting a data snapshot or the replication process, you should record the position of the binary log on the master. You will need this information when configuring the slave so that the slave knows where within the binary log to start executing events. See [Section 15.1.1.4, “Obtaining the Master Replication Information”](#).
- If you already have data on your Master and you want to synchronize your slave with this base data, then you will need to create a data snapshot of your database. You can create a snapshot using `mysqldump` (see [Section 15.1.1.5, “Creating a Data Snapshot using mysqldump”](#)) or by copying the data files directly (see [Section 15.1.1.6, “Creating a Data Snapshot Using Raw Data Files”](#)).
- You will need to configure the slave with the Master settings, such as the hostname, login credentials and binary log name and positions. See [Section 15.1.1.10, “Setting the Master Configuration on the Slave”](#).

Once you have configured the basic options, you will need to follow the instructions for your replication setup. A number of alternatives are provided:

- If you are setting up a new MySQL master and one or more slaves, then you need only setup up the configuration, as you have no data to exchange. For guidance on setting up replication in this situation, see [Section 15.1.1.7, “Setting up Replication with new Master and Slaves”](#).
- If you are already running a MySQL server, and therefore already have data that will need to be transferred to your slaves before replication starts, have not previously configured the binary log and are able to shutdown your MySQL server for a short period during the process, see [Section 15.1.1.8, “Setting up replication with existing data”](#).
- If you are setting up additional slaves to an existing replication environment then you can setup the slaves without affecting the master. See [Section 15.1.1.9, “Introducing Additional Slaves to an Existing Replication Environment”](#).

If you want to administer a MySQL replication setup, we suggest that you read this entire chapter through and try all statements mentioned in [Section 12.6.1, “SQL Statements for Controlling Master Servers”](#), and [Section 12.6.2, “SQL Statements for Controlling Slave Servers”](#). You should also familiarize yourself with the replication startup options described in [Section 15.1.3, “Replication Options and Variables”](#).

Note

Note that certain steps within the setup process require the [SUPER](#) privilege. If you do not have this privilege then enabling replication may not be possible.

15.1.1.1. Creating a User For Replication

Each Slave must connect to the Master using a standard username and password. The user that you use for this operation can be any user, providing they have been granted the [REPLICATION SLAVE](#) privilege.

You do not need to create a specific user for replication. However, you should be aware that the username and password will be stored in plain text within the `master.info` file. Therefore you may want to create a user that only has privileges for the replication process.

To create a user or grant an existing user the privileges required for replication use the [GRANT](#) statement. If you create a user solely for the purposes of replication then that user only needs the [REPLICATION SLAVE](#) privilege. For example, to create a user, `repl`, that allows all hosts within the domain `mydomain.com` to connect for replication:

```
mysql> GRANT REPLICATION SLAVE ON *.*  
-> TO 'repl'@'%mydomain.com' IDENTIFIED BY 'slavepass';
```

See [Section 12.5.1.3, “GRANT Syntax”](#), for more information on the [GRANT](#) statement.

You may wish to create a different user for each slave, or use the same user for each slave that needs to connect. As long as each user that you want to use for the replication process has the [REPLICATION SLAVE](#) privilege you can create as many users as you require.

15.1.1.2. Setting the Replication Master Configuration

For replication to work you *must* enable binary logging on the master. If binary logging is not enabled, replication will not be possible as it is the binary log that is used to exchange data between the master and slaves.

Each server within a replication group must have a unique [server-id](#). The server-id is used to identify individual servers within the group, and must be positive integer between 1 and $(2^{32}-1)$. How you organize and select the numbers is entirely up to you.

To configure both these options you will need to shutdown your MySQL server and edit the configuration of the `my.cnf` or `my.ini` file.

You will need to add the following options to the configuration file within the `[mysqld]` section. If these options already exist, but are commented out, uncomment the options and alter them according to your needs. For example, to enable binary logging, using a log filename prefix of `mysql-bin`, and setting a server ID of 1:

```
[mysqld]  
log-bin=mysql-bin  
server-id=1
```

Note

For the greatest possible durability and consistency in a replication setup using **InnoDB** with transactions, you should use `innodb_flush_log_at_trx_commit=1` and `sync_binlog=1` in the master `my.cnf` file.

Note

Ensure that the `skip-networking` option has not been enabled on your replication master. If networking has been disabled, then your slave will not be able to communicate with the master and replication will fail.

15.1.1.3. Setting the Replication Slave Configuration

The only option you must configure on the slave is to set the unique server ID. If this option is not already set, or the current value conflicts with the value that you have chosen for the master server, then you should shutdown your slave server, and edit the configuration to specify the server id. For example:

```
[mysqld]
server-id=2
```

If you are setting up multiple slaves, each one must have a unique `server-id` value that differs from that of the master and from each of the other slaves. Think of `server-id` values as something similar to IP addresses: These IDs uniquely identify each server instance in the community of replication partners.

If you do not specify a `server-id` value, it is set to 1 if you have not defined `master-host`; otherwise it is set to 2. Note that in the case of `server-id` omission, a master refuses connections from all slaves, and a slave refuses to connect to a master. Thus, omitting `server-id` is good only for backup with a binary log.

You do not have to enable binary logging on the slave for replication to be enabled. However, if you enable binary logging on the slave then you can use the binary log for data backups and crash recovery on the slave, and also use the slave as part of a more complex replication topology.

15.1.1.4. Obtaining the Master Replication Information

To configure replication on the slave you must determine the master's current point within the master binary log. You will need this information so that when the slave starts the replication process, it is able to start processing events from the binary log at the correct point.

If you have existing data on your master that you want to synchronize on your slaves before starting the replication process, then you must stop processing statements on the master, obtain the current position, and then dump the data, before allowing the master to continue executing statements. If you do not stop the execution of statements then the data dump, the master status information that you use will not match and you will end up with inconsistent or corrupted databases on the slaves.

To get the master status information, follow these steps:

1. Start the command line client and flush all tables and block write statements by executing the `FLUSH TABLES WITH READ LOCK` statement:

```
mysql> FLUSH TABLES WITH READ LOCK;
```

For **InnoDB** tables, note that `FLUSH TABLES WITH READ LOCK` also blocks `COMMIT` operations.

Warning

Leave the client from which you issued the `FLUSH TABLES` statement running so that the read lock remains in effect. If you exit the client, the lock is released.

2. Use the `SHOW MASTER STATUS` statement to determine the current binary log name and offset on the master:

```
mysql > SHOW MASTER STATUS;
+-----+-----+-----+-----+
| File           | Position | Binlog_Do_DB | Binlog_Ignore_DB |
+-----+-----+-----+-----+
| mysql-bin.003  | 73       | test         | manual,mysql      |
+-----+-----+-----+-----+
```

The **File** column shows the name of the log and **Position** shows the offset within the file. In this example, the binary log file is `mysql-bin.003` and the offset is 73. Record these values. You need them later when you are setting up the slave. They represent the replication coordinates at which the slave should begin processing new updates from the master.

If the master has been running previously without binary logging enabled, the log name and position values displayed by `SHOW MASTER STATUS` or `mysqldump --master-data` will be empty. In that case, the values that you need to use later when specifying the slave's log file and position are the empty string (`' '`) and 4.

You now have the information you need to enable the slave to start reading from the binary log in the correct place to start replication.

If you have existing data that needs to be synchronised with the slave before you start replication, leave the client running so that the lock remains in place and then proceed to [Section 15.1.1.5, “Creating a Data Snapshot using mysqldump”](#), or [Section 15.1.1.6, “Creating a Data Snapshot Using Raw Data Files”](#).

If you are setting up a brand new master and slave replication group, then you can exit the client and release the locks.

15.1.1.5. Creating a Data Snapshot using `mysqldump`

One way to create a snapshot of the data in an existing master database is to use the `mysqldump` tool. Once the data dump has been completed, you then import this data into the slave before starting the replication process.

To obtain a snapshot of the data using `mysqldump`:

- If you haven't already locked the tables on the server to prevent queries that update data from executing:

Start the command line client and flush all tables and block write statements by executing the `FLUSH TABLES WITH READ LOCK` statement:

```
mysql> FLUSH TABLES WITH READ LOCK;
```

Remember to use `SHOW MASTER STATUS` and record the binary log details for use when starting up the slave. The point in time of your snapshot and the binary log position must match. See [Section 15.1.1.4, “Obtaining the Master Replication Information”](#).

- In another session, use `mysqldump` to create a dump either of all the databases you want to replicate, or by selecting specific databases individually. For example:

```
shell> mysqldump --all-databases --lock-all-tables >dbdump.db
```

- An alternative to using a bare dump, is to use the `--master-data` option, which will automatically append the `CHANGE MASTER` statement required on the slave to start the replication process.

```
shell> mysqldump --all-databases --master-data >dbdump.db
```

When choosing databases to include in the dump, remember that you will need to filter out databases on each slave that you do not want to include in the replication process.

You will need either to copy the dump file to the slave, or to use the file from the master when connecting remotely to the slave to import the data.

15.1.1.6. Creating a Data Snapshot Using Raw Data Files

If your database is particularly large then copying the raw data files may be more efficient than using `mysqldump` and importing the file on each slave.

However, using this method with tables in storage engines with complex cache and/or logging algorithms may not give you a perfect 'in time' snapshot as cache information and logging updates may not have been applied, even if you have acquired a global read lock. How the storage engine responds to this will depend on the crash recovery abilities.

For example, when you have acquired a global read lock, you can start a filesystem snapshot of your **InnoDB** tables. Internally (inside the **InnoDB** storage engine) the snapshot won't be consistent (because the **InnoDB** caches are not flushed), but this is not a cause for

concern, because **InnoDB** resolves this at startup and delivers a consistent result. This means that **InnoDB** can perform crash recovery when started on this snapshot, without corruption. However, there is no way to stop the MySQL server while insuring a consistent snapshot of your **InnoDB** tables.

To create your raw data snapshot you can use standard copy tools such as **cp** or **copy**, a remote copy tool such as **scp** or **rsync** an archiving tool such as **zip** or **tar**, or a file system snapshot tool such as **dump**, providing that your MySQL data files exist on a single filesystem. If you are only replicating certain databases then make sure you only copy those files that related to those tables. For **InnoDB**, all tables in all databases are stored in a single file unless you have the **innodb_file_per_table** option enabled.

You may want to specifically exclude the following files from your archive:

- Files relating to the **mysql** database.
- The **master.info** file.
- The master's binary log files.
- Any relay log files.

To get the most consistent results with a raw data snapshot you should shut down the server during the process, as below:

1. Acquire a read lock and get the master status. See [Section 15.1.1.4, “Obtaining the Master Replication Information”](#).
2. In a separate session, shutdown the MySQL server:

```
shell> mysqladmin shutdown
```

3. Take a copy of the MySQL data files. Examples are shown below for common solutions - you need to choose only one of these solutions:

```
shell> tar cf /tmp/db.tar ./data
shell> zip -r /tmp/db.zip ./data
shell> rsync --recursive ./data /tmp/dbdata
```

4. Startup the MySQL instance on the master.

To get a snapshot of the system from a master without shutting down the database:

1. Acquire a read lock and get the master status. See [Section 15.1.1.4, “Obtaining the Master Replication Information”](#).
2. Take a copy of the MySQL data files. Examples are shown below for common solutions - you need to choose only one of these solutions:

```
shell> tar cf /tmp/db.tar ./data
shell> zip -r /tmp/db.zip ./data
shell> rsync --recursive ./data /tmp/dbdata
```

If you are using **InnoDB** tables, ideally you should use the **InnoDB Hot Backup** tool, which takes a consistent snapshot without acquiring any locks on the master server, and records the log name and offset corresponding to the snapshot to be later used on the slave. **Hot Backup** is an additional non-free (commercial) tool that is not included in the standard MySQL distribution. See the **InnoDB Hot Backup** home page at <http://www.innodb.com/manual.php> for detailed information.

3. In the client where you acquired read lock, free the lock:

```
mysql> UNLOCK TABLES;
```

Once you have created the archive or copy of the database, you will need to copy the files to each slave before starting the slave replication process.

15.1.1.7. Setting up Replication with new Master and Slaves

Setting up replication with a new Master and Slaves (i.e. with no existing data) is the easiest and most straightforward method for setting up replication.

You can also use this method if you are setting up new servers and have an existing dump of the databases that you want to load into your replication configuration. By loading the data onto a new master, the data will be automatically replicated to the slaves.

To set up replication between a new master and slave:

1. Configure the MySQL master with the necessary configuration properties. See [Section 15.1.1.2, “Setting the Replication Master Configuration”](#).
2. Start up the MySQL master.
3. Setup a user, see [Section 15.1.1.1, “Creating a User For Replication”](#).
4. Obtain the master status information. See [Section 15.1.1.4, “Obtaining the Master Replication Information”](#).
5. Free the read lock:

```
mysql> UNLOCK TABLES;
```

6. On the slave, edit the MySQL configuration. See [Section 15.1.1.3, “Setting the Replication Slave Configuration”](#).
7. Start up the MySQL slave.
8. Execute the `CHANGE MASTER` command to set the master replication server configuration.

Because there is no data to load or exchange on a new server configuration you do not need to copy or import any information.

If you are setting up a new replication environment using the data from an existing database server, you will now need to run the dump file on the master. The database updates will automatically be propagated to the slaves:

```
shell> mysql -h master < fulldb.dump
```

15.1.1.8. Setting up replication with existing data

When setting up replication with existing data, you will need to decide how best to get the data from the master to the slave before starting the replication service.

The basic process for setting up replication with existing data is as follows:

1. If you have not already configured the `server-id` and binary logging, you will need to shutdown your master to configure these options. See [Section 15.1.1.2, “Setting the Replication Master Configuration”](#).

If you have to shut down your master database, then this is a good opportunity to take a snapshot of the database. You should obtain the master status (see [Section 15.1.1.4, “Obtaining the Master Replication Information”](#)) before taking the database down, updating the configuration and taking a snapshot. For information on how to create a snapshot using raw data files, see [Section 15.1.1.6, “Creating a Data Snapshot Using Raw Data Files”](#).

2. If your server is already correctly configured, obtain the master status (see [Section 15.1.1.4, “Obtaining the Master Replication Information”](#)) and then use `mysqldump` to take a snapshot (see [Section 15.1.1.5, “Creating a Data Snapshot using mysqldump”](#)) or take a raw snapshot of the live database using the guide in [Section 15.1.1.6, “Creating a Data Snapshot Using Raw Data Files”](#).
3. With the MySQL master running, create a user to be used by the slave when connecting to the master during replication. See [Section 15.1.1.1, “Creating a User For Replication”](#).
4. Update the configuration of the slave, see [Section 15.1.1.3, “Setting the Replication Slave Configuration”](#).
5. The next step depends on how you created the snapshot of data on the master.

If you used `mysqldump`:

- a. Startup the slave, skipping replication by using the `--skip-slave` option.
- b. Import the dump file:

```
shell> mysql < fulldb.dump
```

If you created a snapshot using the raw data files:

- a. Extract the data files into your slave data directory. For example:

```
shell> tar xvf dbdump.tar
```

You may need to set permissions and ownership on the files to match the configuration of your slave.

- b. Startup the slave, skipping replication by using the `--skip-slave` option.
6. Configure the slave with the master status information. This will tell the slave the binary log file and position within the file where replication needs to start, and configure the login credentials and hostname of the master. For more information on the statement required, see [Section 15.1.1.10, “Setting the Master Configuration on the Slave”](#).
7. Start the slave threads:

```
mysql> START SLAVE;
```

After you have performed this procedure, the slave should connect to the master and catch up on any updates that have occurred since the snapshot was taken.

If you have forgotten to set the `server-id` option for the master, slaves cannot connect to it.

If you have forgotten to set the `server-id` option for the slave, you get the following error in the slave's error log:

```
Warning: You should set server-id to a non-0 value if master_host
is set; we will force server id to 2, but this MySQL server will
not act as a slave.
```

You also find error messages in the slave's error log if it is not able to replicate for any other reason.

Once a slave is replicating, you can find in its data directory one file named `master.info` and another named `relay-log.info`. The slave uses these two files to keep track of how much of the master's binary log it has processed. Do *not* remove or edit these files unless you know exactly what you are doing and fully understand the implications. Even in that case, it is preferred that you use the `CHANGE MASTER TO` statement to change replication parameters. The slave will use the values specified in the statement to update the status files automatically.

Note

The content of `master.info` overrides some of the server options specified on the command line or in `my.cnf`. See [Section 15.1.3, “Replication Options and Variables”](#), for more details.

Once you have a snapshot of the master, you can use it to set up other slaves by following the slave portion of the procedure just described. You do not need to take another snapshot of the master; you can use the same one for each slave.

15.1.1.9. Introducing Additional Slaves to an Existing Replication Environment

If you want to add another slave to the existing replication configuration then you can do so without stopping the master. Instead, you duplicate the settings on the slaves.

To duplicate the slave:

1. Shutdown the existing slave (slavea):

```
shell> mysqladmin shutdown
```

2. Copy the data directory from the existing slave to the new slave. You can do this by creating an archive using [tar](#) or [WinZip](#), or by performing a direct copy using a tool such as [cp](#) or [rsync](#). Ensure you also copy the log files and relay log files.
3. Copy the `master.info` and `relay.info` files from the existing slave to the new slave. These files hold the current log positions.
4. Start the existing slave.
5. On the new slave, edit the configuration and give the new slave a new unique `server-id`.
6. Start the new slave; the `master.info` file options will be used to start the replication process.

15.1.1.10. Setting the Master Configuration on the Slave

To setup the slave to communicate with the master for replication, you must tell the slave the necessary connection information. To do this, execute the following statement on the slave, replacing the option values with the actual values relevant to your system:

```
mysql> CHANGE MASTER TO
-> MASTER_HOST='master_host_name',
-> MASTER_USER='replication_user_name',
-> MASTER_PASSWORD='replication_password',
-> MASTER_LOG_FILE='recorded_log_file_name',
-> MASTER_LOG_POS=recorded_log_position;
```

The following table shows the maximum allowable length for the string-valued options:

MASTER_HOST	60
MASTER_USER	16
MASTER_PASSWORD	32
MASTER_LOG_FILE	255

15.1.2. Replication Formats

Replication works because events written to the binary log are read from the master and then processed on the slave. The events are recorded within the binary log in different formats according to the type of event being recorded. The different replication formats used correspond to the binary logging format used when the events were recorded in the master's binary log. The correlation between binary logging formats and the terms used during replication are:

- Replication capabilities in MySQL originally were based on propagation of SQL statements from master to slave. This is called *statement-based replication* (SBR) and this correlates to the standard statement-based binary logging format. Binary logging and replication in MySQL 5.1.4 and earlier, and all previous versions of MySQL, used this format.
- Row-based binary logging logs the physical changes to individual table rows. In replication terms this is *row-based replication* (RBR), the master writes events to the binary log that indicate how individual table rows are affected. Support for RBR was added in MySQL 5.1.5.
- As of MySQL 5.1.8, the binary logging format can be altered on the fly according to the event being logged. With mixed-based logging (and the associated *mixed-based replication* (MBR)), statement-based logging is used by default, but automatically switches to row-based logging in particular cases as described below. See [Section 5.11.4.3, “Mixed Binary Logging \(MBL\) Format”](#).

Starting with MySQL 5.1.12, mixed-based replication (i.e. mixed-based logging) is the default format for all replication environment unless you specify otherwise.

Starting with MySQL 5.1.20, the binary logging format used is partially determined by the storage engine being used and the statement being executed. For more information on mixed-based logging and the rules governing the support of different logging formats, see [Section 5.11.4.3, “Mixed Binary Logging \(MBL\) Format”](#).

There are some known limitations and issues between the different replication formats. For a comparison that shows the advantages and disadvantages of statement-based and row-based replication, see [Section 15.1.2.1, “Comparison of Statement-Based Versus Row-Based Replication”](#).

MySQL Cluster Replication makes use of row-based replication. The NDB storage engine is incompatible with statement-based replication and NDB sets row-based logging format automatically. For more information, see [Section 16.10, “MySQL Cluster Replication”](#).

With MySQL's classic statement-based replication, there may be issues with replicating stored routines or triggers. You can avoid these issues by using MySQL's row-based replication instead. For a detailed list of issues, see [Section 19.4, “Binary Logging of Stored Routines and Triggers”](#).

If you build MySQL from source, row-based replication is available by default unless you invoke `configure` with the `-without-row-based-replication` option.

For MySQL 5.1.20 and later (and MySQL 5.0.46 for backwards compatibility), the following session variables are written to the binary log and honoured by the replication slave when parsing the binary log:

- `SQL_MODE`
- `FOREIGN_KEY_CHECKS`
- `UNIQUE_CHECKS`
- `CHARACTER_SET_CLIENT`
- `COLLATION_CONNECTION`
- `COLLATION_DATABASE`
- `COLLATION_SERVER`
- `SQL_AUTO_IS_NULL`

15.1.2.1. Comparison of Statement-Based Versus Row-Based Replication

Each binary logging format has advantages and disadvantages. For most users, the mixed-based replication format should be fine and should provide the best combination of data integrity and performance. If, however, you want to take advantage of the differences in the replication format when performing specific updates or large data inserts, then the information in this section summarizes the advantages and disadvantages of the row and statement based formats.

Advantages of statement-based replication:

- Proven technology that has existed in MySQL since 3.23.
- Smaller log files. When updates or deletes affect many rows, *much* smaller log files. Smaller log files require less storage space and are faster to back up.
- Log files contain all statements that made any changes, so they can be used to audit the database.
- Log files can be used for point-in-time recovery, not just for replication purposes. See [Section 5.9.3, “Point-in-Time Recovery”](#).
- You can use a slave with a higher version than that used on the master, even when there is a different row structure in the table. This can be useful if you are unable to upgrade the master but want to take advantage of features in a recent slave version, perhaps for testing and evaluation purposes.

Disadvantages of statement-based replication:

- Not all `UPDATE` statements can be replicated: Any non-deterministic behavior (for example, when using random functions in an SQL statement) is hard to replicate when using statement-based replication. For statements that use a non-deterministic user-defined function (UDF), it is not possible to replicate the result using statement-based replication, whereas row-based replication will just replicate the value returned by the UDF.
- Statements cannot be replicated properly if they use a UDF that is non-deterministic (its value depends on other factors than the given parameters).

- Statements that use one of the following functions cannot be replicated properly:

- `LOAD_FILE()`
- `UUID()`
- `USER()`
- `FOUND_ROWS()`
- `SYSDATE()` (unless the server is started with the `--sysdate-is-now` option)

All other functions are replicated correctly (including `RAND()`, `NOW()`, `LOAD DATA INFILE`, and so forth).

- `INSERT ... SELECT` requires a greater number of row-level locks than with row-based replication.
- `UPDATE` statements that require a table scan (because no index is used in the `WHERE` clause) must lock a greater number of rows than with row-based replication.
- For `InnoDB`: An `INSERT` statement that uses `AUTO_INCREMENT` blocks other non-conflicting `INSERT` statements.
- For complex queries, the statement must be evaluated and executed on the slave before the rows are updated or inserted. With row-based replication, the slave only has to run the statement to apply the differences, not the full query.
- Stored functions (not stored procedures) will execute with the same `NOW()` value as the calling statement. (This may be regarded both as a bad thing and a good thing.)
- Deterministic UDFs must be applied on the slaves.
- If there is an error in evaluation on the slave, particularly when executing complex queries, then using statement based replication may slowly increase the margin of error across the affected rows over time.
- Tables have to be (almost) identical on master and slave.

Advantages of row-based replication:

- Everything can be replicated. This is the safest form of replication.

For MySQL versions earlier than 5.1.14, DDL (data definition language) statements such as `CREATE TABLE` are replicated using statement-based replication, while DML (data manipulation language) statements, as well as `GRANT` and `REVOKE` statements, are replicated using row-based-replication.

For MySQL 5.1.14 and later, the `mysql` database is not replicated. The `mysql` database is instead seen as a node specific database. Row-based replication is not supported on this table. Instead, statements that would normally update this information (including `GRANT`, `REVOKE` and the manipulation of triggers, stored routines/procedures and views are all replicated to slaves using Statement based replication.

For statements like `CREATE ... SELECT`, a `CREATE` statement is generated from the table definition and replicated statement-based, while the row insertions are replicated row-based.

- The technology is the same as most other database management systems; knowledge about other systems transfers to MySQL.
- In many cases, it is faster to apply data on the slave for tables that have primary keys.
- Fewer locks needed (and thus higher concurrency) on the master for the following types of statements:
 - `INSERT ... SELECT`
 - `INSERT` statements with `AUTO_INCREMENT`
 - `UPDATE` or `DELETE` statements with `WHERE` clauses that don't use keys or don't change most of the examined rows.
- Fewer locks on the slave for any `INSERT`, `UPDATE`, or `DELETE` statement.
- It's possible to add multiple threads to apply data on the slave in the future (works better on SMP machines).

Disadvantages of row-based replication:

- Larger log files (much larger in some cases).
- Binary log will contain data for large statements that were rolled back.
- When using row-based replication to replicate a statement (for example, an [UPDATE](#) or [DELETE](#) statement), each changed row must be written to the binary log. In contrast, when using statement-based replication, only the statement is written to the binary log. If the statement changes many rows, row-based replication may write significantly more data to the binary log. In these cases the binary log will be locked for a longer time to write the data, which may cause concurrency problems.
- Deterministic UDFs that generate large [BLOB](#) values will be notably slower to replicate.
- You cannot examine the logs to see what statements were executed.
- You cannot see on the slave what statements were received from the master and executed.
- When making a bulk operation that includes non-transactional storage engines, changes are applied as the statement executes. With row-based replication logging, this means that the binary log is written while the statement is running. On the master, this doesn't provide any problems with concurrency, because tables are locked until the bulk operation terminates. On the slave server, however, tables aren't locked while the slave applies changes, because it doesn't know that those changes are part of a bulk operation.

In that scenario, if you retrieve data from a table on the master (for example, [SELECT * FROM table_name](#)), the server will wait for the bulk operation to complete before executing the [SELECT](#) statement, because the table is read-locked. On the slave, the server won't wait (because there is no lock). This means that until the “bulk operation” on the slave has completed you will get different results for the same [SELECT](#) query on the master and on the slave.

This behavior will eventually change, but until it does, you should probably use statement-based replication in a scenario like this.

15.1.3. Replication Options and Variables

This section describes the options that you can use on slave replication servers. You can specify these options either on the command line or in an option file.

On the master and each slave, you must use the [server-id](#) option to establish a unique replication ID. For each server, you should pick a unique positive integer in the range from 1 to $2^{32} - 1$, and each ID must be different from every other ID. Example: [server-id=3](#)

Options that you can use on the master server for controlling binary logging are described in [Section 5.11.4, “The Binary Log”](#).

Certain options are handled in a special way in order to ensure that the active replication configuration is not inadvertently altered or affected. The options affected are shown in this list:

- [--master-host](#)
- [--master-user](#)
- [--master-password](#)
- [--master-port](#)
- [--master-connect-retry](#)
- [--master-ssl](#)
- [--master-ssl-ca](#)
- [--master-ssl-capath](#)
- [--master-ssl-cert](#)
- [--master-ssl-cipher](#)

- `--master-ssl-key`

In MySQL 5.1.17 and later the use of these options is deprecated. The settings they alter are ignored when `mysqld` is started and a warning will be provided in the `mysqld` log. To configure replication, you must use the `CHANGE MASTER TO ...` statement.

In MySQL 5.1.16 and earlier, these options are ignored if the `master.info` file exists (i.e. when the MySQL server has already previously been configured for replication). If the file exists and these options are present in the `my.cnf` or as options on the command line to `mysqld`, they will be silently ignored and the information in `master.info` used instead.

The `master.info` file format in MySQL 5.1 includes values corresponding to the SSL options. In addition, the file format includes as its first line the number of lines in the file. (See [Section 15.4.2, “Replication Relay and Status Files”](#).) If you upgrade an older server (before MySQL 4.1.1) to a newer version, the new server upgrades the `master.info` file to the new format automatically when it starts. However, if you downgrade a newer server to an older version, you should remove the first line manually before starting the older server for the first time.

If no `master.info` file exists when the slave server starts, it uses the values for those options that are specified in option files or on the command line. This occurs when you start the server as a replication slave for the very first time, or when you have run `RESET SLAVE` and then have shut down and restarted the slave.

If the `master.info` file exists when the slave server starts, the server uses its contents and ignores any options that correspond to the values listed in the file. Thus, if you start the slave server with different values of the startup options that correspond to values in the `master.info` file, the different values have no effect, because the server continues to use the `master.info` file. To use different values, you must either restart after removing the `master.info` file or (preferably) use the `CHANGE MASTER TO` statement to reset the values while the slave is running.

Suppose that you specify this option in your `my.cnf` file:

```
[mysqld]
master-host=some_host
```

The first time you start the server as a replication slave, it reads and uses that option from the `my.cnf` file. The server then records the value in the `master.info` file. The next time you start the server, it reads the master host value from the `master.info` file only and ignores the value in the option file. If you modify the `my.cnf` file to specify a different master host of `some_other_host`, the change still has no effect. You should use `CHANGE MASTER TO` instead.

Because the server gives an existing `master.info` file precedence over the startup options just described, you might prefer not to use startup options for these values at all, and instead specify them by using the `CHANGE MASTER TO` statement. See [Section 12.6.2.1, “CHANGE MASTER TO Syntax”](#).

This example shows a more extensive use of startup options to configure a slave server:

```
[mysqld]
server-id=2
master-host=db-master.mycompany.com
master-port=3306
master-user=pertinax
master-password=freitag
master-connect-retry=60
report-host=db-slave.mycompany.com
```

The following list describes the options and variables used for controlling replication. Many of these options can be reset while the server is running by using the `CHANGE MASTER TO` statement. Others, such as the `--replicate-*` options, can be set only when the slave server starts.

- `--log-slave-updates`

Normally, a slave does not log to its own binary log any updates that are received from a master server. This option tells the slave to log the updates performed by its SQL thread to its own binary log. For this option to have any effect, the slave must also be started with the `--log-bin` option to enable binary logging. `--log-slave-updates` is used when you want to chain replication servers. For example, you might want to set up replication servers using this arrangement:

```
A -> B -> C
```

Here, A serves as the master for the slave B, and B serves as the master for the slave C. For this to work, B must be both a master

and a slave. You must start both A and B with `--log-bin` to enable binary logging, and B with the `--log-slave-updates` option so that updates received from A are logged by B to its binary log.

- `--log-warnings[=level]`

This option causes a server to print more messages to the error log about what it is doing. With respect to replication, the server generates warnings that it succeeded in reconnecting after a network/connection failure, and informs you as to how each slave thread started. This option is enabled by default; to disable it, use `--skip-log-warnings`. Aborted connections are not logged to the error log unless the value is greater than 1.

- `--master-connect-retry=seconds`

The number of seconds that the slave thread sleeps before trying to reconnect to the master in case the master goes down or the connection is lost. The value in the `master.info` file takes precedence if it can be read. If not set, the default is 60. Connection retries are not invoked until the slave times out reading data from the master according to the value of `--slave-net-timeout`. The number of reconnection attempts is limited by the `--master-retry-count` option.

- `--master-host=host_name`

The hostname or IP number of the master replication server. The value in `master.info` takes precedence if it can be read. If no master host is specified, the slave thread does not start.

- `--master-info-file=file_name`

The name to use for the file in which the slave records information about the master. The default name is `master.info` in the data directory.

- `--master-password=password`

The password of the account that the slave thread uses for authentication when it connects to the master. The value in the `master.info` file takes precedence if it can be read. If not set, an empty password is assumed.

- `--master-port=port_number`

The TCP/IP port number that the master is listening on. The value in the `master.info` file takes precedence if it can be read. If not set, the compiled-in setting is assumed (normally 3306).

- `--master-retry-count=count`

The number of times that the slave tries to connect to the master before giving up. Reconnects are attempted at intervals set by `--master-connect-retry` and reconnects are triggered when data reads by the slave time out according to the `--slave-net-timeout` option. The default value is 86400.

- `--master-ssl, --master-ssl-ca=file_name, --master-ssl-capath=directory_name, --master-ssl-cert=file_name, --master-ssl-cipher=cipher_list, --master-ssl-key=file_name`

These options are used for setting up a secure replication connection to the master server using SSL. Their meanings are the same as the corresponding `--ssl, --ssl-ca, --ssl-capath, --ssl-cert, --ssl-cipher, --ssl-key` options that are described in [Section 5.8.7.3, “SSL Command Options”](#). The values in the `master.info` file take precedence if they can be read.

- `--master-user=user_name`

The username of the account that the slave thread uses for authentication when it connects to the master. This account must have the `REPLICATION SLAVE` privilege. The value in the `master.info` file takes precedence if it can be read. If the master username is not set, the name `test` is assumed.

- `--max-relay-log-size=size`

The size at which the server rotates relay log files automatically. For more information, see [Section 15.4.2, “Replication Relay and Status Files”](#). The default size is 1GB.

- `--read-only`

Cause the slave to allow no updates except from slave threads or from users having the `SUPER` privilege. This enables you to ensure that a slave server accepts no updates from clients. This option does not apply to `TEMPORARY` tables.

- `--relay-log=file_name`

The basename for the relay log. The default basename is `host_name-relay-bin`. The server creates relay log files in sequence by adding a numeric suffix to the basename. You can specify the option to create hostname-independent relay log names, or if your relay logs tend to be big (and you don't want to decrease `max_relay_log_size`) and you need to put them in some area different from the data directory, or if you want to increase speed by balancing load between disks.

- `--relay-log-index=file_name`

The name to use for the relay log index file. The default name is `host_name-relay-bin.index` in the data directory, where `host_name` is the name of the slave server.

- `--relay-log-info-file=file_name`

The name to use for the file in which the slave records information about the relay logs. The default name is `relay-log.info` in the data directory.

- `--relay-log-purge={0|1}`

Disable or enable automatic purging of relay logs as soon as they are not needed any more. The default value is 1 (enabled). This is a global variable that can be changed dynamically with `SET GLOBAL relay_log_purge = N`.

- `--relay-log-space-limit=size`

This option places an upper limit on the total size in bytes of all relay logs on the slave. A value of 0 means “no limit.” This is useful for a slave server host that has limited disk space. When the limit is reached, the I/O thread stops reading binary log events from the master server until the SQL thread has caught up and deleted some unused relay logs. Note that this limit is not absolute: There are cases where the SQL thread needs more events before it can delete relay logs. In that case, the I/O thread exceeds the limit until it becomes possible for the SQL thread to delete some relay logs, because not doing so would cause a deadlock. You should not set `--relay-log-space-limit` to less than twice the value of `--max-relay-log-size` (or `--max-binlog-size` if `--max-relay-log-size` is 0). In that case, there is a chance that the I/O thread waits for free space because `--relay-log-space-limit` is exceeded, but the SQL thread has no relay log to purge and is unable to satisfy the I/O thread. This forces the I/O thread to temporarily ignore `--relay-log-space-limit`.

- `--replicate-do-db=db_name`

Tell the slave to restrict replication to statements where the default database (that is, the one selected by `USE`) is `db_name`. To specify more than one database, use this option multiple times, once for each database. Note that this does not replicate cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` while having selected a different database or no database.

Warning

To specify multiple databases you *must* use multiple instances of this option. Because database names can contain commas, if you supply a comma separated list then the list will be treated as the name of a single database.

An example of what does not work as you might expect: If the slave is started with `--replicate-do-db=sales` and you issue the following statements on the master, the `UPDATE` statement is *not* replicated:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this “just check the default database” behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` statements or multiple-table `UPDATE` statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

If you need cross-database updates to work, use `--replicate-wild-do-table=db_name.%` instead. See [Section 15.4.3, “How Servers Evaluate Replication Rules”](#).

- `--replicate-do-table=db_name.tbl_name`

Tell the slave thread to restrict replication to the specified table. To specify more than one table, use this option multiple times, once for each table. This works for cross-database updates, in contrast to `--replicate-do-db`. See [Section 15.4.3, “How Servers Evaluate Replication Rules”](#).

- `--replicate-ignore-db=db_name`

Tells the slave to not replicate any statement where the default database (that is, the one selected by `USE`) is `db_name`. To specify more than one database to ignore, use this option multiple times, once for each database. You should not use this option if you are using cross-database updates and you do not want these updates to be replicated. See [Section 15.4.3, “How Servers Evaluate Replication Rules”](#).

An example of what does not work as you might expect: If the slave is started with `--replicate-ignore-db=sales` and you issue the following statements on the master, the `UPDATE` statement is replicated:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

Note

In the preceding example the statement is replicated because `--replicate-ignore-db` only applies to the default database (set through the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered.

If you need cross-database updates to work, use `--replicate-wild-ignore-table=db_name.%` instead. See [Section 15.4.3, “How Servers Evaluate Replication Rules”](#).

- `--replicate-ignore-table=db_name.tbl_name`

Tells the slave thread to not replicate any statement that updates the specified table, even if any other tables might be updated by the same statement. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates, in contrast to `--replicate-ignore-db`. See [Section 15.4.3, “How Servers Evaluate Replication Rules”](#).

- `--replicate-rewrite-db=from_name->to_name`

Tells the slave to translate the default database (that is, the one selected by `USE`) to `to_name` if it was `from_name` on the master. Only statements involving tables are affected (not statements such as `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`), and only if `from_name` is the default database on the master. This does not work for cross-database updates. The database name translation is done *before* the `--replicate-*` rules are tested.

If you use this option on the command line and the ‘>’ character is special to your command interpreter, quote the option value. For example:

```
shell> mysqld --replicate-rewrite-db="olddb->newdb"
```

- `--replicate-same-server-id`

To be used on slave servers. Usually you should use the default setting of 0, to prevent infinite loops caused by circular replication. If set to 1, the slave does not skip events having its own server ID. Normally, this is useful only in rare configurations. Cannot be set to 1 if `--log-slave-updates` is used. Note that by default the slave I/O thread does not even write binary log events to the relay log if they have the slave's server id (this optimization helps save disk usage). So if you want to use `--replicate-same-server-id`, be sure to start the slave with this option before you make the slave read its own events that you want the slave SQL thread to execute.

- `--replicate-wild-do-table=db_name.tbl_name`

Tells the slave thread to restrict replication to statements where any of the updated tables match the specified database and table name patterns. Patterns can contain the ‘%’ and ‘_’ wildcard characters, which have the same meaning as for the `LIKE` pattern-matching operator. To specify more than one table, use this option multiple times, once for each table. This works for cross-database updates. See [Section 15.4.3, “How Servers Evaluate Replication Rules”](#).

Example: `--replicate-wild-do-table=foo%.bar%` replicates only updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

If the table name pattern is %, it matches any table name and the option also applies to database-level statements (`CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`). For example, if you use `--replicate-wild-do-table=foo%.`, database-level statements are replicated if the database name matches the pattern `foo%`.

To include literal wildcard characters in the database or table name patterns, escape them with a backslash. For example, to replicate all tables of a database that is named `my_own$db`, but not replicate tables from the `my1ownAABCDb` database, you should escape

the ‘_’ and ‘%’ characters like this: `--replicate-wild-do-table=my\_own\%db`. If you're using the option on the command line, you might need to double the backslashes or quote the option value, depending on your command interpreter. For example, with the `bash` shell, you would need to type `--replicate-wild-do-table=my\\_own\\%db`.

- `--replicate-wild-ignore-table=db_name.tbl_name`

Tells the slave thread not to replicate a statement where any table matches the given wildcard pattern. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates. See [Section 15.4.3, “How Servers Evaluate Replication Rules”](#).

Example: `--replicate-wild-ignore-table=foo%.bar%` does not replicate updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

For information about how matching works, see the description of the `--replicate-wild-do-table` option. The rules for including literal wildcard characters in the option value are the same as for `--replicate-wild-ignore-table` as well.

- `--report-host=slave_name`

The hostname or IP number of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server. Leave the value unset if you do not want the slave to register itself with the master. Note that it is not sufficient for the master to simply read the IP number of the slave from the TCP/IP socket after the slave connects. Due to NAT and other routing issues, that IP may not be valid for connecting to the slave from the master or other hosts.

- `--report-port=slave_port_num`

The TCP/IP port number for connecting to the slave, to be reported to the master during slave registration. Set this only if the slave is listening on a non-default port or if you have a special tunnel from the master or other clients to the slave. If you are not sure, do not use this option.

- `--report-password=password`

The account password of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the `--show-slave-auth-info` option is given.

- `--report-user=user_name`

The account username of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the `--show-slave-auth-info` option is given.

- `--show-slave-auth-info`

Display slave usernames and passwords in the output of `SHOW SLAVE HOSTS` on the master server for slaves started with the `--report-user` and `--report-password` options.

- `--skip-slave-start`

Tells the slave server not to start the slave threads when the server starts. To start the threads later, use a `START SLAVE` statement.

- `--slave_compressed_protocol={0|1}`

If this option is set to 1, use compression for the slave/master protocol if both the slave and the master support it. The default is 0 (no compression).

- `--slave-load-tmpdir=file_name`

The name of the directory where the slave creates temporary files. This option is by default equal to the value of the `tmpdir` system variable. When the slave SQL thread replicates a `LOAD DATA INFILE` statement, it extracts the file to be loaded from the relay log into temporary files, and then loads these into the table. If the file loaded on the master is huge, the temporary files on the slave are huge, too. Therefore, it might be advisable to use this option to tell the slave to put temporary files in a directory located in some filesystem that has a lot of available space. In that case, the relay logs are huge as well, so you might also want to use the `--relay-log` option to place the relay logs in that filesystem.

The directory specified by this option should be located in a disk-based filesystem (not a memory-based filesystem) because the temporary files used to replicate `LOAD DATA INFILE` must survive machine restarts. The directory also should not be one that is cleared by the operating system during the system startup process.

- `--slave-net-timeout=seconds`

The number of seconds to wait for more data from the master before the slave considers the connection broken, aborts the read, and tries to reconnect. The first retry occurs immediately after the timeout. The interval between retries is controlled by the `--master-connect-retry` option and the number of reconnection attempts is limited by the `--master-retry-count` option. The default is 3600 seconds (one hour).

- `--slave-skip-errors=[err_code1,err_code2,...|all]`

Normally, replication stops when an error occurs on the slave. This gives you the opportunity to resolve the inconsistency in the data manually. This option tells the slave SQL thread to continue replication when a statement returns any of the errors listed in the option value.

Do not use this option unless you fully understand why you are getting errors. If there are no bugs in your replication setup and client programs, and no bugs in MySQL itself, an error that stops replication should never occur. Indiscriminate use of this option results in slaves becoming hopelessly out of synchrony with the master, with you having no idea why this has occurred.

For error codes, you should use the numbers provided by the error message in your slave error log and in the output of `SHOW SLAVE STATUS`. [Appendix B, Errors, Error Codes, and Common Problems](#), lists server error codes.

You can also (but should not) use the very non-recommended value of `all` to cause the slave to ignore all error messages and keeps going regardless of what happens. Needless to say, if you use `all`, there are no guarantees regarding the integrity of your data. Please do not complain (or file bug reports) in this case if the slave's data is not anywhere close to what it is on the master. *You have been warned.*

Examples:

```
--slave-skip-errors=1062,1053
--slave-skip-errors=all
```

15.1.4. Common Replication Administration Tasks

Once replication has been started it should execute without requiring much regular administration. Depending on your replication environment, you will want to check the replication status of each slave either periodically, daily, or even more frequently.

MySQL Enterprise

For regular reports regarding the status of your slaves, subscribe to the MySQL Enterprise Monitor. For more information see <http://www.mysql.com/products/enterprise/advisors.html>.

15.1.4.1. Checking Replication Status

The most common task when managing a replication process is to ensure that replication is taking place and that there have been no errors between the slave and the master.

The primary command for this is `SHOW SLAVE STATUS` which you must execute on each slave:

```
mysql> SHOW SLAVE STATUS\G
***** 1. row *****
Slave_IO_State: Waiting for master to send event
Master_Host: master1
Master_User: root
Master_Port: 3306
Connect_Retry: 60
Master_Log_File: mysql-bin.000004
Read_Master_Log_Pos: 931
Relay_Log_File: slave1-relay-bin.000056
Relay_Log_Pos: 950
Relay_Master_Log_File: mysql-bin.000004
Slave_IO_Running: Yes
Slave_SQL_Running: Yes
Replicate_Do_DB:
Replicate_Ignore_DB:
Replicate_Do_Table:
Replicate_Ignore_Table:
Replicate_Wild_Do_Table:
Replicate_Wild_Ignore_Table:
Last_Errno: 0
Last_Error:
Skip_Counter: 0
Exec_Master_Log_Pos: 931
```

```

Relay_Log_Space: 1365
Until_Condition: None
Until_Log_File:
Until_Log_Pos: 0
Master_SSL_Allowed: No
Master_SSL_CA_File:
Master_SSL_CA_Path:
Master_SSL_Cert:
Master_SSL_Cipher:
Master_SSL_Key:
Seconds_Behind_Master: 0
1 row in set (0.01 sec)

```

The key fields from the status report to examine are:

- **Slave_IO_State** — indicates the current status of the slave. See [Section 6.5.5.5, “Replication Slave I/O Thread States”](#), and [Section 6.5.5.6, “Replication Slave SQL Thread States”](#), for more information.
- **Slave_IO_Running** — shows whether the IO thread for the reading the master's binary log is running.
- **Slave_SQL_Running** — shows whether the SQL thread for the executing events in the relay log is running.
- **Last_Error** — shows the last error registered when processing the relay log. Ideally this should be blank, indicating no errors.
- **Seconds_Behind_Master** — shows the number of seconds that the slave SQL thread is behind processing the master binary log. A high number (or an increasing one) can indicate that the slave is unable to cope with the large number of queries from the master.

On the master, you can check the status of slaves by examining the list of running processes. Slaves execute the **Binlog Dump** command:

```

mysql> SHOW PROCESSLIST \G;
***** 4. row *****
   Id: 10
  User: root
 Host: slave1:58371
   db: NULL
Command: Binlog Dump
   Time: 777
  State: Has sent all binlog to slave; waiting for binlog to be updated
   Info: NULL

```

Because it is the slave that drives the core of the replication process, very little information is available in this report.

If you have used the **--report-host** option, then the **SHOW SLAVE HOSTS** statement will show basic information about connected slaves:

```

mysql> SHOW SLAVE HOSTS;
+-----+-----+-----+-----+-----+
| Server_id | Host | Port | Rpl_recovery_rank | Master_id |
+-----+-----+-----+-----+-----+
| 10 | slave1 | 3306 | 0 | 1 |
+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)

```

The output includes the ID of the slave server, the value of the **--report-host** option, the connecting port, master ID and the priority of the slave for receiving binary log updates.

15.1.4.2. Pausing Replication on the Slave

You can stop and start the replication of statements on the slave using the **STOP SLAVE** and **START SLAVE** commands.

To stop execution of the binary log from the master, use **STOP SLAVE**:

```
mysql> STOP SLAVE;
```

When execution is stopped, the slave does not read the binary log from the master (the **IO_THREAD**) and stops processing events from the relay log that have not yet been executed (the **SQL_THREAD**). You can pause either the IO or SQL threads individually by specifying the thread type. For example:

```
mysql> STOP SLAVE IO_THREAD;
```

Stopping the SQL thread can be useful if you want to perform a backup or other task on a slave that only processes events from the master. The IO thread will continue to be read from the master, but not executed, which will make it easier for the slave to catch up when you start slave operations again.

Stopping the IO thread will allow the statements in the relay log to be executed up until the point where the relay log has ceased to receive new events. Using this option can be useful when you want to pause execution to allow the slave to catch up with events from the master, when you want to perform administration on the slave but also ensure you have the latest updates to a specific point. This method can also be used to pause execution on the slave while you conduct administration on the master while ensuring that there is not a massive backlog of events to be executed when replication is started again.

To start execution again, use the `START SLAVE` statement:

```
mysql> START SLAVE;
```

If necessary, you can start either the `IO_THREAD` or `SQL_THREAD` threads individually.

15.2. Replication Solutions

Replication can be used in many different environments for a range of purposes. In this section you will find general notes and advice on using replication for specific solution types.

For information on using replication in a backup environment, including notes on the setup, backup procedure, and files to backup, see [Section 15.2.1, “Using Replication for Backups”](#).

For advice and tips on using different storage engines on the master and slaves, see [Section 15.2.2, “Using Replication with different Master and Slave Storage Engines”](#).

Using replication as a scale-out solution requires some changes in the logic and operation of applications that use the solution. See [Section 15.2.3, “Using Replication for Scale-out”](#).

For performance or data distribution reasons you may want to replicate different databases to different replication slaves. See [Section 15.2.4, “Replicating Different Databases to Different Slaves”](#).

As the number of replication slaves increases, the load on the master can increase (because of the need to replicate the binary log to each slave) and lead to a reduction in performance of the master. For tips on improving your replication performance, including using a single secondary server as an replication master, see [Section 15.2.5, “Improving Replication Performance”](#).

For guidance on switching masters, or converting slaves into masters as part of an emergency failover solution, see [Section 15.2.6, “Switching Masters During Failover”](#).

To secure your replication communication you can encrypt the communication channel by using SSL to exchange data. Step-by-step instructions can be found in [Section 15.2.7, “Setting up Replication using SSL”](#).

15.2.1. Using Replication for Backups

You can use replication as a backup solution by replicating data from the master to a slave, and then backing up the data slave. Because the slave can be paused and shutdown without affecting the running operation of the master you can produce an effective snapshot of 'live' data that would otherwise require a shutdown of the master database.

How you back up the database will depend on the size of the database and whether you are backing up only the data, or the data and the replication slave state so that you can rebuild the slave in the event of failure. There are therefore two choices:

If you are using replication as a solution to enable you to backup the data on the master, and the size of your database is not too large, then the `mysqldump` tool may be suitable. See [Section 15.2.1.1, “Backing up using mysqldump”](#).

For larger databases, where `mysqldump` would be impractical or inefficient, you can backup the raw data files instead. Using the raw data files option also means that you can backup the binary and relay logs that will enable you to recreate the slave in the event of a slave failure. For more information, see [Section 15.2.1.2, “Backing up raw data”](#).

15.2.1.1. Backing up using `mysqldump`

Using `mysqldump` to create a copy of the database enables you to capture all of the data in the database in a format that allows the information to be imported into another instance of MySQL. Because the format of the information is SQL statements the file can easily be distributed and applied to running servers in the event that you need access to the data in an emergency. However, if the size of your data set is very large then `mysqldump` may be impractical.

When using `mysqldump` you should stop the slave before starting the dump process to ensure that the dump contains a consistent set of data:

1. Stop the slave from processing requests. You can either stop the slave completely using `mysqladmin`:

```
shell> mysqladmin stop-slave
```

Alternatively, you can stop processing the relay log files by stopping the replication SQL thread. Using this method will allow the binary log data to be transferred. Within busy replication environments this may speed up the catch-up process when you start the slave processing again:

```
shell> mysql -e 'STOP SLAVE SQL_THREAD;'
```

2. Run `mysqldump` to dump your databases. You may either select databases to be dumped, or dump all databases. For more information see [Section 7.13, “mysqldump — A Database Backup Program”](#). For example, to dump all databases:

```
shell> mysqldump --all-databases >fulldb.dump
```

3. Once the dump has completed, start slave operations again:

```
shell> mysqladmin start-slave
```

In the preceding example you may want to add login credentials (username, password) to the commands, and bundle the process up into a script that you can run automatically each day.

If you use this approach, make sure you monitor the slave replication process to ensure that the time taken to run the backup in this way is not affecting the slaves ability to keep up with events from the master. See [Section 15.1.4.1, “Checking Replication Status”](#). If the slave is unable to keep up you may want to add another server and distribute the backup process. For an example of how to configure this scenario, see [Section 15.2.4, “Replicating Different Databases to Different Slaves”](#).

15.2.1.2. Backing up raw data

To guarantee the integrity of the files that are copied, backing up the raw data files on your MySQL replication slave should take place while your slave server is shutdown. If the MySQL server is still running then background tasks, particularly with storage engines with background processes such as InnoDB, may still be updating the database files. With InnoDB, these problems should be resolved during crash recovery, but since the slave server can be shutdown during the backup process without affecting the execution of the master it makes sense to take advantage of this facility.

To shutdown the server and backup the files:

1. Shutdown the slave MySQL server:

```
shell> mysqladmin shutdown
```

2. Copy the data files. You can use any suitable copying or archive utility, including `cp`, `tar` or `WinZip`:

```
tar cf /tmp/dbbackup.tar ./data
```

3. Start up the `mysqld` process again:

```
shell> mysqld_safe &
```

Under Windows:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.1\bin\mysqld"
```

Normally you should back up the entire data folder for the slave MySQL server. If you want to be able to restore the data and operate as a slave (for example, in the event of failure of the slave), then when you back up the slave's data, you should back up the slave status files, `master.info` and `relay.info`, along with the relay log files. These files are needed to resume replication after you restore the slave's data.

If you lose the relay logs but still have the `relay-log.info` file, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use `CHANGE MASTER TO` with the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options to tell the slave to re-read the binary logs from that point. Of course, this requires that the binary logs still exist on the master server.

If your slave is subject to replicating `LOAD DATA INFILE` statements, you should also back up any `SQL_LOAD-*` files that exist in the directory that the slave uses for this purpose. The slave needs these files to resume replication of any interrupted `LOAD DATA INFILE` operations. The directory location is specified using the `--slave-load-tmpdir` option. If this option is not specified, the directory location is the value of the `tmpdir` system variable.

15.2.2. Using Replication with different Master and Slave Storage Engines

The replication process does not care if the source table on the master and the replicated table on the slave use different engine types. In fact, the system variables `storage_engine` and `table_type` are not replicated.

This provides a number of advantages in the replication process in that you can take advantage of different engine types for different replication scenarios. For example, in a typical scaleout scenario (see [Section 15.2.3, “Using Replication for Scale-out”](#)), you want to use `InnoDB` tables on the master to take advantage of the transactional functionality, but use `MyISAM` on the slaves where transaction support is not required because the data is only read. When using replication in a data logging environment you may want to use the `Archive` storage engine on the slave.

Setting up different engines on the master and slave depends on how you set up the initial replication process:

- If you used `mysqldump` to create the database snapshot on your master then you could edit the dump text to change the engine type used on each table.

Another alternative for `mysqldump` is to disable engine types that you do not want to use on the slave before using the dump to build the data on the slave. For example, you can add the `--skip-innodb` option on your slave to disable the `InnoDB` engine. If a specific engine does not exist, MySQL will use the default engine type, usually `MyISAM`. If you want to disable further engines in this way, you may want to consider building a special binary to be used on the slave that only supports the engines you want.

- If you are using raw data files for the population of the slave, you will be unable to change the initial table format. Instead, use `ALTER TABLE` to change the table types after the slave has been started.
- For new master/slave replication setups where there are currently no tables on the master, avoid specifying the engine type when creating new tables.

If you are already running a replication solution and want to convert your existing tables to another engine type, follow these steps:

1. Stop the slave from running replication updates:

```
mysql> STOP SLAVE;
```

This will enable you to change engine types without interruptions.

2. Execute an `ALTER TABLE ... Engine='enginetype'` for each table where you want to change the engine type.
3. Start the slave replication process again:

```
mysql> START SLAVE;
```

Although the `storage_engine` and `table_type` variables are not replicated, be aware that `CREATE TABLE` and `ALTER TABLE` statements that include the engine specification will be correctly replicated to the slave. For example, if you have a CSV table and you execute:

```
mysql> ALTER TABLE csvtable Engine='MyISAM';
```

The above statement will be replicated to the slave and the engine type on the slave will be converted to [MyISAM](#), even if you have previously changed the table type on the slave to an engine other than CSV. If you want to retain engine differences on the master and slave, you should be careful to use the [storage_engine](#) variable on the master when creating a new table. For example, instead of:

```
mysql> CREATE TABLE tablea (columna int) Engine=MyISAM;
```

Use this format:

```
mysql> SET storage_engine=MyISAM;
mysql> CREATE TABLE tablea (columna int);
```

When replicated, the [storage_engine](#) variable will be ignored, and the [CREATE TABLE](#) statement will be executed with the slave's default engine type.

15.2.3. Using Replication for Scale-out

You can use replication as a scale-out solution, i.e. where you want to split up the load of database queries across multiple database servers, within some reasonable limitations.

Because replication works from the distribution of one master to one or more slaves, using replication for scaleout works best in an environment where you have a high number of reads and low number of writes/updates. Most websites fit into this category, where users are browsing the website, reading articles, posts, or viewing products. Updates only occur during session management, or when making a purchase or adding a comment/message to a forum.

Replication in this situation enables you to distribute the reads over the replication slaves, while still allowing your web servers to communicate with the replication master when a write is required. You can see a sample replication layout for this scenario in [Figure 15.1](#), “Using replication to improve the performance during scaleout”.

Figure 15.1. Using replication to improve the performance during scaleout

If the part of your code that is responsible for database access has been properly abstracted/modularized, converting it to run with a replicated setup should be very smooth and easy. Change the implementation of your database access to send all writes to the master, and to send reads to either the master or a slave. If your code does not have this level of abstraction, setting up a replicated system gives you the opportunity and motivation to clean it up. Start by creating a wrapper library or module that implements the following functions:

- `safe_writer_connect()`

- `safe_reader_connect()`
- `safe_reader_statement()`
- `safe_writer_statement()`

`safe_` in each function name means that the function takes care of handling all error conditions. You can use different names for the functions. The important thing is to have a unified interface for connecting for reads, connecting for writes, doing a read, and doing a write.

Then convert your client code to use the wrapper library. This may be a painful and scary process at first, but it pays off in the long run. All applications that use the approach just described are able to take advantage of a master/slave configuration, even one involving multiple slaves. The code is much easier to maintain, and adding troubleshooting options is trivial. You need modify only one or two functions; for example, to log how long each statement took, or which statement among those issued gave you an error.

If you have written a lot of code, you may want to automate the conversion task by using the `replace` utility that comes with standard MySQL distributions, or write your own conversion script. Ideally, your code uses consistent programming style conventions. If not, then you are probably better off rewriting it anyway, or at least going through and manually regularizing it to use a consistent style.

15.2.4. Replicating Different Databases to Different Slaves

There may be situations where you have a single master and want to replicate different databases to different slaves. For example, you may want to distribute different sales data to different departments to help spread the load during data analysis. A sample of this layout is shown in [Figure 15.2, “Using replication to replicate separate DBs to multiple hosts”](#).

Figure 15.2. Using replication to replicate separate DBs to multiple hosts

You can achieve this separation by configuring the master and slaves as normal, and then limiting the binary log statements that each slave processes by using the `replicate-wild-do-table` configuration option on each slave.

For example, to support the separation as shown in [Figure 15.2, “Using replication to replicate separate DBs to multiple hosts”](#), you would configure each slave as follows before enabling replication using `START SLAVE`:

- MySQL Slave 1 should have the following configuration options:

```
replicate-wild-do-table=sales.%
replicate-wild-do-table=finance.%
```

- MySQL Slave 2 should have the following configuration option:

```
replicate-wild-do-table=support.%
```

- MySQL Slave 3 should have the following configuration option:

```
replicate-wild-do-table=service.%
```

If you have data that needs to be synchronized to the slaves before replication starts, you have a number of options:

- Synchronize all the data to each slave, and delete the databases and/or tables that you do not want to keep.
- Use `mysqldump` to create a separate dump file for each database and load the appropriate dump file on each slave.
- Use a raw data file dump and include only the specific files and databases that you need for each slave. This option will not work with InnoDB databases unless you use the `innodb_file_per_table` option.

Each slave in this configuration will transfer to the entire binary log from the master, but will only execute the events within the binary log that apply to the configured databases and tables.

15.2.5. Improving Replication Performance

As the number of slaves connecting to a master increases, the load, although minimal, also increases, as each slave uses up a client connection to the master. Also, as each slave must receive a full copy of the master binary log, the network load on the master may also increase and start to create a bottleneck.

If you are using a large number of slaves connected to one master, and that master is also busy processing requests (for example, as part of a scaleout solution), then you may want to improve the performance of the replication process.

One way to improve the performance of the replication process is to create a deeper replication structure that enables the master to replicate to only one slave, and for the remaining slaves to connect to this primary slave for their individual replication requirements. A sample of this structure is shown in [Figure 15.3, “Using an additional replication host to improve performance”](#).

Figure 15.3. Using an additional replication host to improve performance

For this to work, you must configure the MySQL instances as follows:

- Master 1 is the primary master where all changes and updates are written to the database. Binary logging should be enabled on this machine.
- Master 2 is the slave to the Master 1 that provides the replication functionality to the remainder of the slaves in the replication structure. Master 2 is the only machine allowed to connect to Master 1. Master 2 also has binary logging enabled, and the `-log-slave-updates` option so that replication instructions from Master 1 are also written to Master 2's binary log so that they can then be replicated to the true slaves.
- Slave 1, Slave 2, and Slave 3 act as slaves to Master 2, and replicate the information from Master 2, which is really the data logged

on Master 1.

The above solution reduces the client load and the network interface load on the primary master, which should improve the overall performance of the primary master when used as a direct database solution.

If your slaves are having trouble keeping up with the replication process on the master then there are a number of options available:

- If possible, you should put the relay logs and the data files on different physical drives. To do this, use the `--relay-log` option to specify the location of the relay log.
- If the slaves are significantly slower than the master, then you may want to divide up the responsibility for replicating different databases to different slaves. See [Section 15.2.4, “Replicating Different Databases to Different Slaves”](#).
- If your master makes use of transactions and you are not concerned about transaction support on your slaves, then use [MyISAM](#) or another non-transactional engine. See [Section 15.2.2, “Using Replication with different Master and Slave Storage Engines”](#).
- If your slaves are not acting as masters, and you have a potential solution in place to ensure that you can bring up a master in the event of failure, then you can switch off `--log-slave-updates`. This prevents 'dumb' slaves from also logging events they have executed into their own binary log.

15.2.6. Switching Masters During Failover

There is currently no official solution for providing failover between master and slaves in the event of a failure. With the currently available features, you would have to set up a master and a slave (or several slaves), and to write a script that monitors the master to check whether it is up. Then instruct your applications and the slaves to change master in case of failure.

Remember that you can tell a slave to change its master at any time, using the `CHANGE MASTER TO` statement. The slave will not check whether the databases on the master are compatible with the slave, it will just start executing events from the specified log and position on the new master. In a failover situation all the servers in the group are probably executing the same events from the same binary log, so changing the source of the events should not affect the database structure or integrity providing you are careful.

Run your slaves with the `--log-bin` option and without `--log-slave-updates`. In this way, the slave is ready to become a master as soon as you issue `STOP SLAVE; RESET MASTER`, and `CHANGE MASTER TO` statement on the other slaves. For example, assume that you have the structure shown in [Figure 15.4, “Redundancy using replication, initial structure”](#).

Figure 15.4. Redundancy using replication, initial structure

In this diagram, the **MySQL Master** holds the master database, the **MySQL Slave** computers are replication slaves, and the **Web Client** machines are issuing database reads and writes. Web clients that issue only reads (and would normally be connected to the slaves) are not shown, as they do not need to switch to a new server in the event of failure. For a more detailed example of a read/write scaleout replication structure, see [Section 15.2.3, “Using Replication for Scale-out”](#).

Each **MySQL Slave** (**Slave 1**, **Slave 2**, and **Slave 3**) are slaves running with `--log-bin` and without `--log-slave-updates`. Because updates received by a slave from the master are not logged in the binary log unless `--log-slave-updates` is specified, the binary log on each slave is empty initially. If for some reason **MySQL Master** becomes unavailable, you can pick one of the slaves to become the new master. For example, if you pick **Slave 1**, all **Web Clients** should be redirected to **Slave 1**, which will log updates to its binary log. **Slave 2** and **Slave 3** should then replicate from **Slave 1**.

The reason for running the slave without `--log-slave-updates` is to prevent slaves from receiving updates twice in case you cause one of the slaves to become the new master. Suppose that **Slave 1** has `--log-slave-updates` enabled. Then it will write updates that it receives from **Master** to its own binary log. When **Slave 2** changes from **Master** to **Slave 1** as its master, it may receive updates from **Slave 1** that it has already received from **Master**.

Make sure that all slaves have processed any statements in their relay log. On each slave, issue `STOP SLAVE IO_THREAD`, then check the output of `SHOW PROCESSLIST` until you see `Has read all relay log`. When this is true for all slaves, they can be reconfigured to the new setup. On the slave **Slave 1** being promoted to become the master, issue `STOP SLAVE` and `RESET MASTER`.

On the other slaves **Slave 2** and **Slave 3**, use `STOP SLAVE` and `CHANGE MASTER TO MASTER_HOST='Slave1'` (where `'Slave1'` represents the real hostname of **Slave 1**). To `CHANGE MASTER`, add all information about how to connect to **Slave 1** from **Slave 2** or **Slave 3** (`user`, `password`, `port`). In `CHANGE MASTER`, there is no need to specify the name of **Slave 1**'s binary log or binary log position to read from: We know it is the first binary log and position 4, which are the defaults for `CHANGE MASTER`. Finally, use `START SLAVE` on **Slave 2** and **Slave 3**.

Once the new replication is in place, you will then need to instruct each **Web Client** to direct their statements to **Slave 1**. From that point on, all updates statements sent by **Web Client** to **Slave 1** are written to the binary log of **Slave 1**, which then contains

every update statement sent to **Slave 1** since **Master** died.

The resulting server structure is shown in [Figure 15.5, “Redundancy using replication, after master failure”](#).

Figure 15.5. Redundancy using replication, after master failure

When **Master** is up again, you must issue on it the same **CHANGE MASTER** as that issued on **Slave 2** and **Slave 3**, so that **Master** becomes a slave of **S1** and picks up each **Web Client** writes that it missed while it was down.

To make **Master** a master again (because it is the most powerful machine, for example), use the preceding procedure as if **Slave 1** was unavailable and **Master** was to be the new master. During this procedure, do not forget to run **RESET MASTER** on **Master** before making **Slave 1**, **Slave 2**, and **Slave 3** slaves of **Master**. Otherwise, they may pick up old **Web Client** writes from before the point at which **Master** became unavailable.

Note that there is no synchronization between the different slaves to a master. Some slaves might be ahead of others. This means that the concept outlined in the previous example might not work. In practice, however, the relay logs of different slaves will most likely not be far behind the master, so it would work, anyway (but there is no guarantee).

A good way to keep your applications informed as to the location of the master is by having a dynamic DNS entry for the master. With **bind** you can use **nsupdate** to dynamically update your DNS.

15.2.7. Setting up Replication using SSL

Setting up replication using an SSL connection is similar to setting up a server and client using SSL. You will need to obtain (or create) a suitable security certificate that you can use on the master, and a similar certificate (from the same certificate authority) on each slave.

To use SSL for encrypting the transfer of the binary log required during replication you must first set up the master to support SSL network connections. If the master does not support SSL connections (because it has not been compiled or configured for SSL), then replication through an SSL connection will not be possible.

For more information on setting up a server and client for SSL connectivity, see [Section 5.8.7.2, “Using SSL Connections”](#).

To enable SSL on the master you will need to create or obtain suitable certificates and then add the following configuration options to the master's configuration within the `mysqld` section:

```
ssl-ca=cacert.pem
ssl-cert=server-cert.pem
ssl-key=server-key.pem
```

The options are as follows:

- `ssl-ca` identifies the Certificate Authority (CA) certificate.
- `ssl-cert` identifies the server public key. This can be sent to the client and authenticated against the CA certificate that it has.
- `ssl-key` identifies the server private key.

On the slave, you have two options available for setting the SSL information. You can either add the slaves certificates to the `client` section of the slave configuration file, or you can explicitly specify the SSL information using the `CHANGE MASTER` statement.

Using the former option, add the following lines to the `client` section of the slave configuration file:

```
[client]
ssl-ca=cacert.pem
ssl-cert=server-cert.pem
ssl-key=server-key.pem
```

Restart the slave server, using the `--skip-slave` to prevent the slave from connecting to the master. Use `CHANGE MASTER` to specify the master configuration, using the `master_ssl` option to enable SSL connectivity:

```
mysql> CHANGE MASTER TO \
  MASTER_HOST='master_hostname', \
  MASTER_USER='replicate', \
  MASTER_PASSWORD='password', \
  MASTER_SSL=1;
```

To specify the SSL certificate options during the `CHANGE MASTER` command, append the SSL options:

```
CHANGE MASTER TO \
  MASTER_HOST='master_hostname', \
  MASTER_USER='replicate', \
  MASTER_PASSWORD='password', \
  MASTER_SSL=1, \
  MASTER_SSL_CA = 'ca_file_name', \
  MASTER_SSL_CAPATH = 'ca_directory_name', \
  MASTER_SSL_CERT = 'cert_file_name', \
  MASTER_SSL_KEY = 'key_file_name';
```

Once the master information has been updated, start the slave replication process:

```
mysql> START SLAVE;
```

You can use the `SHOW SLAVE STATUS` to confirm that SSL connection has been completed.

For more information on the `CHANGE MASTER TO` syntax, see [Section 12.6.2.1, “CHANGE MASTER TO Syntax”](#).

If you want to enforce SSL connections to be used during replication, then create a user with the `REPLICATION SLAVE` privilege and use the `REQUIRE_SSL` option for that user. For example:

```
mysql> GRANT REPLICATION SLAVE ON *.*
```

```
-> TO 'repl'@'%.mydomain.com' IDENTIFIED BY 'slavepass' REQUIRE SSL;
```

15.3. Replication Notes and Tips

15.3.1. Replication Features and Issues

In general, replication compatibility at the SQL level requires that any features used be supported by both the master and the slave servers. If you use a feature on a master server that is available only as of a given version of MySQL, you cannot replicate to a slave that is older than that version. Such incompatibilities are likely to occur between series, so that, for example, you cannot replicate from MySQL 5.1 to 5.0. However, these incompatibilities also can occur for within-series replication. For example, the `SLEEP()` function is available in MySQL 5.0.12 and up. If you use this function on the master server, you cannot replicate to a slave server that is older than MySQL 5.0.12.

If you are planning to use replication between 5.1 and a previous version of MySQL you should consult the edition of the MySQL Reference Manual corresponding to the earlier release series for information regarding the replication characteristics of that series.

The following sections provide details about what is supported and what is not, and about specific issues and situations that may occur when replicating certain statements. Additional **InnoDB**-specific information about replication is given in [Section 13.5.6.5, “InnoDB and MySQL Replication”](#).

With MySQL's classic statement-based replication, there may be issues with replicating stored routines or triggers. You can avoid these issues by using MySQL's row-based replication instead. For a detailed list of issues, see [Section 19.4, “Binary Logging of Stored Routines and Triggers”](#). For a description of row-based replication, see [Section 15.1.2, “Replication Formats”](#).

15.3.1.1. Replication and **AUTO_INCREMENT**

Replication of **AUTO_INCREMENT**, `LAST_INSERT_ID()`, and **TIMESTAMP** values is done correctly, subject to the following exceptions.

A stored procedure that uses `LAST_INSERT_ID()` does not replicate properly using statement-based binary logging. This limitation is lifted in MySQL 5.1.12.

Adding an **AUTO_INCREMENT** column to a table with `ALTER TABLE` might not produce the same ordering of the rows on the slave and the master. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the master and slave, the rows must be ordered before assigning an **AUTO_INCREMENT** number. Assuming that you want to add an **AUTO_INCREMENT** column to the table `t1`, the following statements produce a new table `t2` identical to `t1` but with an **AUTO_INCREMENT** column:

```
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

This assumes that the table `t1` has columns `col1` and `col2`.

Important

To guarantee the same ordering on both master and slave, *all* columns of `t1` must be referenced in the `ORDER BY` clause.

The instructions just given are subject to the limitations of `CREATE TABLE ... LIKE`: Foreign key definitions are ignored, as are the **DATA DIRECTORY** and **INDEX DIRECTORY** table options. If a table definition includes any of those characteristics, create `t2` using a `CREATE TABLE` statement that is identical to the one used to create `t1`, but with the addition of the **AUTO_INCREMENT** column.

Regardless of the method used to create and populate the copy having the **AUTO_INCREMENT** column, the final step is to drop the original table and then rename the copy:

```
DROP t1;
ALTER TABLE t2 RENAME t1;
```

See also [Section B.1.7.1, “Problems with ALTER TABLE”](#).

15.3.1.2. Replication and Character Sets

The following applies to replication between MySQL servers that use different character sets:

1. If the master uses MySQL 4.1, you must *always* use the same *global* character set and collation on the master and the slave, regardless of the MySQL version running on the slave. (These are controlled by the `--character-set-server` and `--collation-server` options.) Otherwise, you may get duplicate-key errors on the slave, because a key that is unique in the master character set might not be unique in the slave character set. Note that this is not a cause for concern when master and slave are both MySQL 5.0 or later.
2. If the master is older than MySQL 4.1.3, the character set of any client should never be made different from its global value because this character set change is not known to the slave. In other words, clients should not use `SET NAMES`, `SET CHARACTER SET`, and so forth. If both the master and the slave are 4.1.3 or newer, clients can freely set session values for character set variables because these settings are written to the binary log and so are known to the slave. That is, clients can use `SET NAMES` or `SET CHARACTER SET` or can set variables such as `collation_client` or `collation_server`. However, clients are prevented from changing the *global* value of these variables; as stated previously, the master and slave must always have identical global character set values.
3. If you have databases on the master with character sets that differ from the global `character_set_server` value, you should design your `CREATE TABLE` statements so that tables in those databases do not implicitly rely on the database default character set. A good workaround is to state the character set and collation explicitly in `CREATE TABLE` statements.

15.3.1.3. Replication of `CREATE TABLE ... SELECT` Statements

The following rules and decisions are applied when a `CREATE TABLE ... SELECT` statement is replicated:

- All `CREATE TABLE ... SELECT` statements do implicit commit.
- If there are no failures, then all `CREATE TABLE ... SELECT` statements are replicated as follows:
 - For `STATEMENT` and `MIXED` format, as the `CREATE TABLE ... SELECT` statement itself.
 - For `ROW` format, as a `CREATE TABLE` statement followed by binwrite events.
- Requirements for `CREATE TABLE t2 SELECT ...` using both transactional and non-transactional tables:
 - For `STATEMENT`, `MIXED`, and `ROW` formats:
 - If the table already exists, then the statement does nothing on the master, and only the implicit commit is logged.
 - If other execution failure (and thus `t2` did not exist), then the table is never created on master and only the implicit commit is logged.
- Requirements for `CREATE TABLE IF NOT EXISTS t2 SELECT ...`
 - For `STATEMENT` and `MIXED` format:

If execution failure, then statement is logged with error code.
 - For `ROW` format when `t2` is transactional:
 - If table already exists, then
 - The `CREATE TABLE` part of the statement is not logged.
 - All applied rows are logged.
 - The implicit commit is logged.
 - If other failure in creating table, then only the implicit commit is logged.
 - If failure in selecting or inserting (but create succeeded), then the table is dropped on master and only the implicit commit is logged.
 - For `ROW` format when `t2` is non-transactional:

- If table already exists, then:
 - the `CREATE TABLE` part of the statement is not logged.
 - All applied rows are logged.
 - The implicit commit is logged.
- If other failure in creating table, then only the implicit commit is logged.
- If failure in selecting or inserting (but create succeeded), then:
 - The `CREATE TABLE` part of the statement is logged.
 - All applied rows are logged.
 - The implicit commit is logged.

15.3.1.4. Replication and `DIRECTORY` Statements

If a `DATA DIRECTORY` or `INDEX DIRECTORY` table option is used in a `CREATE TABLE` statement on the master server, the table option is also used on the slave. This can cause problems if no corresponding directory exists in the slave host filesystem or if it exists but is not accessible to the slave server. MySQL supports an `sql_mode` option called `NO_DIR_IN_CREATE`. If the slave server is run with this SQL mode enabled, it ignores the `DATA DIRECTORY` and `INDEX DIRECTORY` table options when replicating `CREATE TABLE` statements. The result is that `MyISAM` data and index files are created in the table's database directory.

15.3.1.5. Replication of Invoked Features

Replication of invoked features such as scheduled events, user-defined functions (UDFs), stored routines (including both stored procedures and stored functions), and triggers was re-implemented in MySQL 5.1.18 to provide the following characteristics:

- The effects of the feature are always replicated.
- The following statements are replicated using statement-based replication:
 - `CREATE EVENT`
 - `ALTER EVENT`
 - `DROP EVENT`
 - `CREATE PROCEDURE`
 - `DROP PROCEDURE`
 - `CREATE FUNCTION`
 - `DROP FUNCTION`
 - `CREATE TRIGGER`
 - `DROP TRIGGER`

However, the *effects* of features created, modified, or dropped using these statements are replicated using row-based replication.

- In the case of `CREATE EVENT` and `ALTER EVENT`:
 - The status of the event is set to `SLAVESIDE_DISABLED` on the slave regardless of the state specified (this does not apply to `DROP EVENT`).
 - The master on which the event was created is identified on the slave by its server ID. The `ORIGINATOR` column in `INFORMATION_SCHEMA.EVENTS` and the `originator` column in `mysql.event` were added to these tables in MySQL 5.1.18 to

store this information. (See [Section 23.20](#), “The `INFORMATION_SCHEMA` `EVENTS` Table, and [Section 12.5.4.16](#), “`SHOW EVENTS`”.)

- The feature implementation resides on the slave in a renewable state so that if the master fails, the slave can be used as the master without loss of event processing.

To determine whether there are any scheduled events on a MySQL server that were created on a different server (that was acting as a replication master), use `SHOW EVENTS`, like this:

```
SHOW EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED';
```

Alternatively, you might wish to query the `INFORMATION_SCHEMA.EVENTS` table as shown here:

```
SELECT EVENT_SCHEMA, EVENT_NAME, ORIGINATOR
FROM INFORMATION_SCHEMA.EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED';
```

When promoting a replication slave having such events to a replication master, use the following query to enable the events:

```
UPDATE mysql.event
SET STATUS = 'ENABLED'
WHERE STATUS = 'SLAVESIDE_DISABLED';
```

If more than one master was involved in creating events on this slave, and you wish to enable events that were created only on a given master having the server ID `master_id`, use the following query instead:

```
UPDATE mysql.event
SET STATUS = 'ENABLED'
WHERE ORIGINATOR = master_id
AND STATUS = 'SLAVESIDE_DISABLED';
```

Important

Before executing either of the previous two `UPDATE` statements, you should disable the Event Scheduler on the slave (using `SET GLOBAL EVENT_SCHEDULER = OFF;`), run the `UPDATE`, restart the server, then re-enable the Event Scheduler afterwards (using `SET GLOBAL EVENT_SCHEDULER = ON;`).

If you later demote the new master back to being a replication slave, you must disable manually all events enabled by the `UPDATE` statement. You can do this by storing in a separate table the event names from the `SELECT` statement shown previously, or using an `UPDATE` statement to rename the events with a common prefix to identify them, as shown in this example:

```
UPDATE mysql.event
SET name = CONCAT('replicated_', name)
WHERE status = 'SLAVESIDE_DISABLED';
```

When demoting this server back to being a replication slave, you can then rename and disable the events like this:

```
UPDATE mysql.event
SET name = REPLACE(name, 'replicated_', ''),
status = 'SLAVESIDE_DISABLED'
WHERE INSTR(name, 'replicated_') = 1;
```

15.3.1.6. Replication with Floating Point Values

Floating-point values are approximate, so comparisons involving them are inexact. This is true for operations that use floating-point values explicitly, or values that are converted to floating-point implicitly. Comparisons of floating-point values might yield different results on master and slave servers due to differences in computer architecture, the compiler used to build MySQL, and so forth. See [Section 11.2.2](#), “Type Conversion in Expression Evaluation”, and [Section B.1.5.8](#), “Problems with Floating-Point Comparisons”.

15.3.1.7. Replication and `FLUSH`

Some forms of the `FLUSH` statement are not logged because they could cause problems if replicated to a slave: `FLUSH LOGS`, `FLUSH MASTER`, `FLUSH SLAVE`, and `FLUSH TABLES WITH READ LOCK`. For a syntax example, see [Section 12.5.5.2](#), “`FLUSH` Syntax”. The `FLUSH TABLES`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements are written to the binary log and thus replicated to slaves. This is not normally a problem because these statements do not modify table data. However, this can cause dif-

difficulties under certain circumstances. If you replicate the privilege tables in the `mysql` database and update those tables directly without using `GRANT`, you must issue a `FLUSH PRIVILEGES` on the slaves to put the new privileges into effect. In addition, if you use `FLUSH TABLES` when renaming a `MyISAM` table that is part of a `MERGE` table, you must issue `FLUSH TABLES` manually on the slaves. These statements are written to the binary log unless you specify `NO_WRITE_TO_BINLOG` or its alias `LOCAL`.

15.3.1.8. Replication and System Functions

Certain functions do not replicate well under some conditions:

- The `USER()`, `CURRENT_USER()`, `UUID()`, `VERSION()`, and `LOAD_FILE()` functions are replicated without change and thus do not work reliably on the slave unless row-based replication is enabled. (See [Section 15.1.2](#), “Replication Formats”.)

For early implementations of mixed-format logging, stored functions, triggers, and views that use these functions in their body do not replicate reliably in mixed-format logging mode because the logging did not switch from statement-based to row-based format. For example, `INSERT INTO t SELECT FROM v`, where `v` is a view that selects `UUID()` could cause problems. This limitation is lifted in MySQL 5.1.12.

- Unlike `NOW()`, the `SYSDATE()` function is not replication-safe because it is not affected by `SET TIMESTAMP` statements in the binary log and is non-deterministic if statement-based logging is used. This is not a problem if row-based logging is used. Another option is to start the server with the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`.
- The following restriction applies to statement-based replication only, not to row-based replication.* The `GET_LOCK()`, `RELEASE_LOCK()`, `IS_FREE_LOCK()`, and `IS_USED_LOCK()` functions that handle user-level locks are replicated without the slave knowing the concurrency context on master. Therefore, these functions should not be used to insert into a master's table because the content on the slave would differ. (For example, do not issue a statement such as `INSERT INTO mytable VALUES(GET_LOCK(...))`.)

As a workaround for the preceding limitations when statement-based replication is in effect, you can use the strategy of saving the problematic function result in a user variable and referring to the variable in a later statement. For example, the following single-row `INSERT` is problematic due to the reference to the `UUID()` function:

```
INSERT INTO t VALUES(UUID());
```

To work around the problem, do this instead:

```
SET @my_uuid = UUID();
INSERT INTO t VALUES(@my_uuid);
```

That sequence of statements replicates because the value of `@my_uuid` is stored in the binary log as a user-variable event prior to the `INSERT` statement and is available for use in the `INSERT`.

The same idea applies to multiple-row inserts, but is more cumbersome to use. For a two-row insert, you can do this:

```
SET @my_uuid1 = UUID(); @my_uuid2 = UUID();
INSERT INTO t VALUES(@my_uuid1),(@my_uuid2);
```

However, if the number of rows is large or unknown, the workaround is difficult or impracticable. For example, you cannot convert the following statement to one in which a given individual user variable is associated with each row:

```
INSERT INTO t2 SELECT UUID(), * FROM t1;
```

15.3.1.9. Replication during a Master Crash

A crash on the master side can result in the master's binary log having a final position less than the most recent position read by the slave, due to the master's binary log file not being flushed. This can cause the slave not to be able to replicate when the master comes back up. Setting `sync_binlog=1` in the master `my.cnf` file helps to minimize this problem because it causes the master to flush its binary log more frequently.

15.3.1.10. Replication during a Master Shutdown

It is safe to shut down a master server and restart it later. When a slave loses its connection to the master, the slave tries to reconnect immediately and retries periodically if that fails. The default is to retry every 60 seconds. This may be changed with the -

`-master-connect-retry` option. A slave also is able to deal with network connectivity outages. However, the slave notices the network outage only after receiving no data from the master for `slave_net_timeout` seconds. If your outages are short, you may want to decrease `slave_net_timeout`. See [Section 5.2.3, “System Variables”](#).

15.3.1.11. Replication with **MEMORY** Table Types

When a server shuts down and restarts, its **MEMORY** tables become empty. The master replicates this effect to slaves as follows: The first time that the master uses each **MEMORY** table after startup, it logs an event that notifies the slaves that the table needs to be emptied by writing a **DELETE** statement for that table to the binary log. See [Section 13.7, “The MEMORY \(HEAP\) Storage Engine”](#), for more information about **MEMORY** tables.

15.3.1.12. Replication of the System **mysql** Database

For MySQL 5.1.14 and later, the **mysql** database is not replicated. The **mysql** database is instead seen as a node specific database. Row-based replication is not supported on this table. Instead, statements that would normally update this information (including **GRANT**, **REVOKE**, and the manipulation of triggers, stored routines/procedures, and views) are all replicated to slaves using Statement based replication.

For MySQL 5.1.13 and earlier, user privileges are replicated only if the **mysql** database is replicated. That is, the **GRANT**, **REVOKE**, **SET PASSWORD**, **CREATE USER**, and **DROP USER** statements take effect on the slave only if the replication setup includes the **mysql** database.

If you're replicating all databases, but don't want statements that affect user privileges to be replicated, set up the slave to not replicate the **mysql** database, using the `--replicate-wild-ignore-table=mysql.%` option. The slave will recognize that issuing privilege-related SQL statements won't have an effect, and thus not execute those statements.

15.3.1.13. Slave Errors during Replication

If a statement on a slave produces an error, the slave SQL thread terminates, and the slave writes a message to its error log. You should then connect to the slave manually and determine the cause of the problem. (`SHOW SLAVE STATUS` is useful for this.) Then fix the problem (for example, you might need to create a non-existent table) and run `START SLAVE`.

MySQL Enterprise

For instant notification when a slave thread terminates subscribe to the MySQL Enterprise Monitor. For more information see <http://www.mysql.com/products/enterprise/advisors.html>.

15.3.1.14. Replication during a Slave Shutdown

Shutting down the slave (cleanly) is also safe because it keeps track of where it left off. Unclean shutdowns might produce problems, especially if the disk cache was not flushed to disk before the system went down. Your system fault tolerance is greatly increased if you have a good uninterruptible power supply. Unclean shutdowns of the master may cause inconsistencies between the content of tables and the binary log in master; this can be avoided by using **InnoDB** tables and the `--innodb-safe-binlog` option on the master. See [Section 5.11.4, “The Binary Log”](#).

15.3.1.15. Replication and Temporary Tables

This item does not apply when row-based replication is in use because in that case temporary tables are not replicated (see [Section 15.1.2, “Replication Formats”](#)).

Temporary tables are replicated except in the case where you shut down the slave server (not just the slave threads) and you have replicated temporary tables that are used in updates that have not yet been executed on the slave. If you shut down the slave server, the temporary tables needed by those updates are no longer available when the slave is restarted. To avoid this problem, do not shut down the slave while it has temporary tables open. Instead, use the following procedure:

1. Issue a `STOP SLAVE` statement.
2. Use `SHOW STATUS` to check the value of the `Slave_open_temp_tables` variable.
3. If the value is 0, issue a `mysqladmin shutdown` command to stop the slave.
4. If the value is not 0, restart the slave threads with `START SLAVE`.
5. Repeat the procedure later until the `Slave_open_temp_tables` variable is 0 and you can stop the slave.

15.3.1.16. Replication Retries and Timeouts

The global system variable `slave_transaction_retries` affects replication as follows: If the replication slave SQL thread fails to execute a transaction because of an `InnoDB` deadlock or because it exceeded the `InnoDB innodb_lock_wait_timeout` value, or the `NDBCluster TransactionDeadlockDetectionTimeout` or `TransactionInactiveTimeout` value, the transaction is automatically retried `slave_transaction_retries` times before stopping with an error. The default value is 10. The total retry count can be seen in the output of `SHOW STATUS`; see [Section 5.2.5, “Status Variables”](#).

15.3.1.17. Replication and Time zones

If the master uses MySQL 4.1, the same system time zone should be set for both master and slave. Otherwise some statements will not be replicated properly, such as statements that use the `NOW()` or `FROM_UNIXTIME()` functions. You can set the time zone in which MySQL server runs by using the `--timezone=timezone_name` option of the `mysqld_safe` script or by setting the `TZ` environment variable. Both master and slave should also have the same default connection time zone setting; that is, the `--default-time-zone` parameter should have the same value for both master and slave. Note that this is not necessary when the master is MySQL 5.0 or later.

`CONVERT_TZ(..., ..., @@session.time_zone)` is properly replicated only if both master and slave are running MySQL 5.0.4 or newer.

15.3.1.18. Replication and Transactions

It is possible to replicate transactional tables on the master using non-transactional tables on the slave. For example, you can replicate an `InnoDB` master table as a `MyISAM` slave table. However, if you do this, there are problems if the slave is stopped in the middle of a `BEGIN/COMMIT` block because the slave restarts at the beginning of the `BEGIN` block.

In situations where transactions mix updates to transactional and non-transactional tables, the order of statements in the binary log is correct, and all needed statements are written to the binary log even in case of a `ROLLBACK`. However, when a second connection updates the non-transactional table before the first connection's transaction is complete, statements can be logged out of order, because the second connection's update is written immediately after it is performed, regardless of the state of the transaction being performed by the first connection.

Due to the non-transactional nature of `MyISAM` tables, it is possible to have a statement that only partially updates a table and returns an error code. This can happen, for example, on a multiple-row insert that has one row violating a key constraint, or if a long update statement is killed after updating some of the rows. If that happens on the master, the slave thread exits and waits for the database administrator to decide what to do about it unless the error code is legitimate and execution of the statement results in the same error code on the slave. If this error code validation behavior is not desirable, some or all errors can be masked out (ignored) with the `--slave-skip-errors` option.

Caution

You should not use transactions in a replication environment that update both transactional and non-transactional tables.

When the storage engine type of the slave is non-transactional, transactions on the master that mix updates of transactional and non-transactional tables should be avoided because they can cause inconsistency of the data between the master's transactional table and the slave's non-transactional table. That is, such transactions can lead to master storage engine-specific behavior with the possible effect of replication going out of synchrony. MySQL does not issue a warning about this currently, so extra care should be taken when replicating transactional tables from the master to non-transactional ones on the slaves.

15.3.1.19. Replication with More Columns on the Slave

Note

Starting with MySQL 5.1.21 you can replicate from master to slave using a different number of columns and (within limits) different table definitions. See [Section 15.3.1.20, “Replication with Fewer Columns on the Slave”](#).

You may replicate from a master to a slave where the number of columns in the table on the slave is larger than the number of columns in the corresponding table on the master.

When replicating tables from the master to tables on a slave with extra columns, the following must be met:

- You must be using row-based replication.

- Master and slave must have the same database/table name.
- Slave tables may contain additional columns compared to the Master, but the columns must appear sequentially after the corresponding columns on the Master.
- All the matching columns on the Master and the Slave must have the same type.
- Every extra column on the slave must have a default value.

This functionality was added in MySQL 5.1.12.

15.3.1.20. Replication with Fewer Columns on the Slave

Starting with MySQL 5.1.21 you can replicate from master to slave with a different number of columns (fewer or greater) on each host.

- You must be using row-based replication.
- Master and slave must have the same database/table name.
- Slave tables may contain additional columns compared to the Master, but the columns must appear sequentially after the corresponding columns on the Master. For example, the following definitions would replicate correctly:

```
mysql> CREATE TABLE master (first INT, second INT);
mysql> CREATE TABLE slave (first INT, second INT, third INT);
```

But these table definitions would raise error **1532 SQLSTATE: HY000 (ER_BINLOG_ROW_RBR_TO_SBR)** because the column definitions on the slave are in a different order than the master:

```
mysql> CREATE TABLE master (first INT, second INT);
mysql> CREATE TABLE slave (third INT, second INT, first INT);
```

- Master tables can have more columns compared to the columns on the slave, but the additional columns on the master must appear after the matching columns in the server. The following table definitions would be valid:

```
mysql> CREATE TABLE master (first INT, second INT, third INT);
mysql> CREATE TABLE slave (first INT, second INT);
```

But these table definitions would raise error 1532 because the column definitions on the slave are in a different order than the master:

```
mysql> CREATE TABLE master (third INT, second INT, first INT);
mysql> CREATE TABLE slave (first INT, second INT);
```

- Columns on the master and slave should have the same type, but within certain limits, this is not strictly enforced:
 - For numeric column types, the types must match. There is no conversion between **INT** and **FLOAT** types.
 - **BINARY**, **VARBINARY**, **CHAR** and **VARCHAR** columns are treated as equal. Therefore you can replicate from **CHAR** to **BINARY**.
 - For **CHAR** and **BINARY** column types, the column size on the slave must be at least equal to the column size on the master. If the column size on the master is greater than on the slave, error 1532 will be raised.
- When replicating with between a master and the slave where the number of columns on the slave is greater than on the master, every additional column on the slave must have a default value.

15.3.1.21. Replication and Variables

The **FOREIGN_KEY_CHECKS**, **SQL_MODE**, **UNIQUE_CHECKS**, and **SQL_AUTO_IS_NULL** variables are all replicated (this has been true since MySQL 5.0). The **storage_engine** system variable (also known as **table_type**) is not yet replicated in MySQL 5.1, which is a good thing for replication between different storage engines.

Session variables are not replicated properly when used in statements that update tables. For example, **SET MAX_JOIN_SIZE=1000**

followed by `INSERT INTO mytable VALUES(@@MAX_JOIN_SIZE)` will not insert the same data on the master and the slave. This does not apply to the common sequence of `SET TIME_ZONE=...` followed by `INSERT INTO mytable VALUES(CONVERT_TZ(..., @@time_zone))`.

Replication of session variables is not a problem when row-based replication is being used. See [Section 15.1.2, “Replication Formats”](#).

15.3.1.22. Replication and Views

Views are always replicated to slaves. Views are filtered by their own name, not by the tables they refer to. This means that a view can be replicated to the slave even if the view contains a table that would normally be filtered out by [replication-ignore-table](#) rules. Care should therefore be taken to ensure that views do not replicate table data that would normally be filtered for security reasons.

15.3.2. Replication Compatibility Between MySQL Versions

The binary log format as implemented in MySQL 5.1 is considerably different from that used in previous versions, especially with regard to handling of character sets, `LOAD DATA INFILE`, and time zones.

As a general rule, you should setup replication only between masters and slaves running the same major versions (5.1, 5.0 or 4.1) of MySQL. If you must execute replication between different major versions, ensure that your client is at a version equal to or higher than that of the master. For example, a master of 4.1.23 and a slave of 5.0.24.

We recommend using the most recent MySQL version available because replication capabilities are continually being improved. We also recommend using the same version for both the master and the slave. We recommend upgrading masters and slaves running alpha or beta versions to new (production) versions. In many cases, replication from a newer master to an older slave will fail. In general, slaves running MySQL 5.1.x can be used with older masters (even those running MySQL 3.23, 4.0, or 4.1), but not the reverse.

Note

You *cannot* replicate from a master that uses a newer binary log format to a slave that uses an older format (for example, from MySQL 5.0 to MySQL 4.1.) This has significant implications for upgrading replication servers, as described in [Section 15.3.3, “Upgrading a Replication Setup”](#).

The preceding information pertains to replication compatibility at the protocol level. However, there can be other constraints, such as SQL-level compatibility issues. For example, a 5.1 master cannot replicate to a 5.0 slave if the replicated statements use SQL features available in 5.1 but not in 5.0. These and other issues are discussed in [Section 15.3.1, “Replication Features and Issues”](#).

15.3.3. Upgrading a Replication Setup

When you upgrade servers that participate in a replication setup, the procedure for upgrading depends on the current server versions and the version to which you are upgrading.

This section applies to upgrading replication from MySQL 3.23, 4.0, or 4.1 to MySQL 5.1. A 4.0 server should be 4.0.3 or newer.

When you upgrade a master to 5.1 from an earlier MySQL release series, you should first ensure that all the slaves of this master are using the same 5.1.x release. If this is not the case, you should first upgrade the slaves. To upgrade each slave, shut it down, upgrade it to the appropriate 5.1.x version, restart it, and restart replication. The 5.1 slave is able to read the old relay logs written prior to the upgrade and to execute the statements they contain. Relay logs created by the slave after the upgrade are in 5.1 format.

After the slaves have been upgraded, shut down the master, upgrade it to the same 5.1.x release as the slaves, and restart it. The 5.1 master is able to read the old binary logs written prior to the upgrade and to send them to the 5.1 slaves. The slaves recognize the old format and handle it properly. Binary logs created by the master following the upgrade are in 5.1 format. These too are recognized by the 5.1 slaves.

In other words, there are no measures to take when upgrading to MySQL 5.1, except that the slaves must be MySQL 5.1 before you can upgrade the master to 5.1. Note that downgrading from 5.1 to older versions does not work so simply: You must ensure that any 5.1 binary logs or relay logs have been fully processed, so that you can remove them before proceeding with the downgrade.

Downgrading a replication setup to a previous version cannot be done once you've switched from statement-based to row-based replication, and after the first row-based statement has been written to the binlog. See [Section 15.1.2, “Replication Formats”](#).

15.3.4. Replication FAQ

MySQL Enterprise

For expert advice on replication subscribe to the MySQL Enterprise Monitor. For more information see [ht-](#)

[tp://www.mysql.com/products/enterprise/advisors.html](http://www.mysql.com/products/enterprise/advisors.html).

Questions and Answers

16.3.4.1: Does the slave need to be connected to the master all the time?

No, it does not. The slave can go down or stay disconnected for hours or even days, and then reconnect and catch up on updates. For example, you can set up a master/slave relationship over a dial-up link where the link is up only sporadically and for short periods of time. The implication of this is that, at any given time, the slave is not guaranteed to be in sync with the master unless you take some special measures.

To ensure that this is the case, you must not remove binary logs from the master, where the information has not been replicated to the slaves. Asynchronous replication can only work if the slave is able to read the binary log from the last point in the binary logs where it had read the replication statements.

16.3.4.2: Do I have to enable networking on my master to enable replication?

Networking must be enabled on the master. If networking is not enabled, then the slave is unable to connect to the master and transfer the binary log. Check that the [skip-networking](#) option has not been enabled in your configuration file.

16.3.4.3: How do I know how late a slave is compared to the master? In other words, how do I know the date of the last statement replicated by the slave?

You can read the [Seconds_Behind_Master](#) column in `SHOW SLAVE STATUS`. See [Section 15.4.1, “Replication Implementation Details”](#).

When the slave SQL thread executes an event read from the master, it modifies its own time to the event timestamp. (This is why [TIMESTAMP](#) is well replicated.) In the [Time](#) column in the output of `SHOW PROCESSLIST`, the number of seconds displayed for the slave SQL thread is the number of seconds between the timestamp of the last replicated event and the real time of the slave machine. You can use this to determine the date of the last replicated event. Note that if your slave has been disconnected from the master for one hour, and then reconnects, you may immediately see [Time](#) values like 3600 for the slave SQL thread in `SHOW PROCESSLIST`. This is because the slave is executing statements that are one hour old.

16.3.4.4: How do I force the master to block updates until the slave catches up?

Use the following procedure:

1. On the master, execute these statements:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SHOW MASTER STATUS;
```

Record the replication coordinates (the log filename and offset) from the output of the `SHOW` statement.

2. On the slave, issue the following statement, where the arguments to the `MASTER_POS_WAIT()` function are the replication coordinate values obtained in the previous step:

```
mysql> SELECT MASTER_POS_WAIT('log_name', log_offset);
```

The `SELECT` statement blocks until the slave reaches the specified log file and offset. At that point, the slave is in synchrony with the master and the statement returns.

3. On the master, issue the following statement to allow the master to begin processing updates again:

```
mysql> UNLOCK TABLES;
```

16.3.4.5: What issues should I be aware of when setting up two-way replication?

MySQL replication currently does not support any locking protocol between master and slave to guarantee the atomicity of a distributed (cross-server) update. In other words, it is possible for client A to make an update to co-master 1, and in the meantime, before it propagates to co-master 2, client B could make an update to co-master 2 that makes the update of client A work differently than it did on co-master 1. Thus, when the update of client A makes it to co-master 2, it produces tables that are different from what you have on co-master 1, even after all the updates from co-master 2 have also propagated. This means that you should not chain two servers together in a two-way replication relationship unless you are sure that your updates can safely happen in any order, or unless you take care of mis-ordered updates somehow in the client code.

You should also realize that two-way replication actually does not improve performance very much (if at all) as far as updates are concerned. Each server must do the same number of updates, just as you would have a single server do. The only difference is that there is a little less lock contention, because the updates originating on another server are serialized in one slave thread. Even this benefit might be offset by network delays.

16.3.4.6: How can I use replication to improve performance of my system?

You should set up one server as the master and direct all writes to it. Then configure as many slaves as you have the budget and rack-space for, and distribute the reads among the master and the slaves. You can also start the slaves with the `--skip-innodb`, `--low-priority-updates`, and `--delay-key-write=ALL` options to get speed improvements on the slave end. In this case, the slave uses non-transactional `MyISAM` tables instead of `InnoDB` tables to get more speed by eliminating transactional overhead.

16.3.4.7: What should I do to prepare client code in my own applications to use performance-enhancing replication?

See the guide to using replication as a scale-out solution, [Section 15.2.3, “Using Replication for Scale-out”](#).

16.3.4.8: When and how much can MySQL replication improve the performance of my system?

MySQL replication is most beneficial for a system that processes frequent reads and infrequent writes. In theory, by using a single-master/multiple-slave setup, you can scale the system by adding more slaves until you either run out of network bandwidth, or your update load grows to the point that the master cannot handle it.

To determine how many slaves you can use before the added benefits begin to level out, and how much you can improve performance of your site, you need to know your query patterns, and to determine empirically by benchmarking the relationship between the throughput for reads (reads per second, or `reads`) and for writes (`writes`) on a typical master and a typical slave. The example here shows a rather simplified calculation of what you can get with replication for a hypothetical system.

Let's say that system load consists of 10% writes and 90% reads, and we have determined by benchmarking that `reads` is $1200 - 2 \times \text{writes}$. In other words, the system can do 1,200 reads per second with no writes, the average write is twice as slow as the average read, and the relationship is linear. Let us suppose that the master and each slave have the same capacity, and that we have one master

and N slaves. Then we have for each server (master or slave):

`reads = 1200 - 2 × writes`

`reads = 9 × writes / (N + 1)` (reads are split, but writes go to all servers)

`9 × writes / (N + 1) + 2 × writes = 1200`

`writes = 1200 / (2 + 9/(N+1))`

The last equation indicates the maximum number of writes for N slaves, given a maximum possible read rate of 1,200 per minute and a ratio of nine reads per write.

This analysis yields the following conclusions:

- If $N = 0$ (which means we have no replication), our system can handle about $1200/11 = 109$ writes per second.
- If $N = 1$, we get up to 184 writes per second.
- If $N = 8$, we get up to 400 writes per second.
- If $N = 17$, we get up to 480 writes per second.
- Eventually, as N approaches infinity (and our budget negative infinity), we can get very close to 600 writes per second, increasing system throughput about 5.5 times. However, with only eight servers, we increase it nearly four times.

Note that these computations assume infinite network bandwidth and neglect several other factors that could be significant on your system. In many cases, you may not be able to perform a computation similar to the one just shown that accurately predicts what will happen on your system if you add N replication slaves. However, answering the following questions should help you decide whether and by how much replication will improve the performance of your system:

- What is the read/write ratio on your system?
- How much more write load can one server handle if you reduce the reads?
- For how many slaves do you have bandwidth available on your network?

16.3.4.9: How can I use replication to provide redundancy or high availability?

How you implement redundancy is entirely dependent on your application and circumstances. High-availability solutions (with automatic failover) require active monitoring and either custom scripts or third party tools to provide the failover support from the original MySQL server to the slave.

To handle the process manually, you should be able to switch from a failed master to a pre-configured slave by altering your application to talk to the new server or by adjusting the DNS for the MySQL server from the failed server to the new server.

For more information and some example solutions, see [Section 15.2.6, “Switching Masters During Failover”](#).

16.3.4.10: How do I tell whether a master server is using statement-based or row-based binary logging format?

Check the value of the `binlog_format` system variable:

```
mysql> SHOW VARIABLES LIKE 'binlog_format';
```

The value will be either `STATEMENT` or `ROW`.

16.3.4.11: How do I tell a slave to use row-based replication?

Slaves automatically know which format to use.

16.3.4.12: How do I prevent GRANT and REVOKE statements from replicating to slave machines?

Start the server with the `--replicate-wild-ignore-table=mysql.%` option.

16.3.4.13: Does replication work on mixed operating systems (for example, the master runs on Linux while slaves run on Mac OS X and Windows)?

Yes.

16.3.4.14: Does replication work on mixed hardware architectures (for example, the master runs on a 64-bit machine while slaves run on 32-bit machines)?

Yes.

15.3.5. Troubleshooting Replication

If you have followed the instructions, and your replication setup is not working, the first thing to do is *check the error log for messages*. Many users have lost time by not doing this soon enough after encountering problems.

If you cannot tell from the error log what the problem was, try the following techniques:

- Verify that the master has binary logging enabled by issuing a `SHOW MASTER STATUS` statement. If logging is enabled, `Position` is non-zero. If binary logging is not enabled, verify that you are running the master with the `--log-bin` and `--server-id` options.
- Verify that the slave is running. Use `SHOW SLAVE STATUS` to check whether the `Slave_IO_Running` and `Slave_SQL_Running` values are both `Yes`. If not, verify the options that were used when starting the slave server. For example, `--skip-slave-start` prevents the slave threads from starting until you issue a `START SLAVE` statement.
- If the slave is running, check whether it established a connection to the master. Use `SHOW PROCESSLIST`, find the I/O and SQL threads and check their `State` column to see what they display. See [Section 15.4.1, “Replication Implementation Details”](#). If the I/O thread state says `Connecting to master`, check the following:
 - Verify the privileges for the user being used for replication on the master.
 - Check that the hostname of the master is correct and that you are using the correct port to connect to the master. The port used for replication is the same as used for client network communication (the default is `3306`). For the hostname, ensure that the name resolves to the correct IP address.
 - Check that networking on the master and slave have not been disabled. Look for the `skip-networking` option in the configuration file. It should either be commented out or deleted entirely.
 - If the master has a firewall or IP filtering configuration, ensure that the network port being used for MySQL is not being filtered.
 - Check that you can reach the master by using `ping` or `traceroute/tracert` to reach the host.
- If the slave was running previously but has stopped, the reason usually is that some statement that succeeded on the master failed on the slave. This should never happen if you have taken a proper snapshot of the master, and never modified the data on the slave outside of the slave thread. If the slave stops unexpectedly, it is a bug or you have encountered one of the known replication limitations described in [Section 15.3.1, “Replication Features and Issues”](#). If it is a bug, see [Section 15.3.6, “How to Report Replication Bugs or Problems”](#), for instructions on how to report it.
- If a statement that succeeded on the master refuses to run on the slave, try the following procedure if it is not feasible to do a full database resynchronization by deleting the slave's databases and copying a new snapshot from the master:
 1. Determine whether the affected table on the slave is different from the master table. Try to understand how this happened. Then make the slave's table identical to the master's and run `START SLAVE`.
 2. If the preceding step does not work or does not apply, try to understand whether it would be safe to make the update manually (if needed) and then ignore the next statement from the master.
 3. If you decide that you can skip the next statement from the master, issue the following statements:

```
mysql> SET GLOBAL SQL_SLAVE_SKIP_COUNTER = N;  
mysql> START SLAVE;
```

The value of `N` should be 1 if the next statement from the master does not use `AUTO_INCREMENT` or `LAST_INSERT_ID()`. Otherwise, the value should be 2. The reason for using a value of 2 for statements that use `AUTO_INCREMENT` or

`LAST_INSERT_ID()` is that they take two events in the binary log of the master.

4. If you are sure that the slave started out perfectly synchronized with the master, and that no one has updated the tables involved outside of the slave thread, then presumably the discrepancy is the result of a bug. If you are running the most recent version of MySQL, please report the problem. If you are running an older version, try upgrading to the latest production release to determine whether the problem persists.

15.3.6. How to Report Replication Bugs or Problems

When you have determined that there is no user error involved, and replication still either does not work at all or is unstable, it is time to send us a bug report. We need to obtain as much information as possible from you to be able to track down the bug. Please spend some time and effort in preparing a good bug report.

If you have a repeatable test case that demonstrates the bug, please enter it into our bugs database using the instructions given in [Section 1.8, “How to Report Bugs or Problems”](#). If you have a “phantom” problem (one that you cannot duplicate at will), use the following procedure:

1. Verify that no user error is involved. For example, if you update the slave outside of the slave thread, the data goes out of synchrony, and you can have unique key violations on updates. In this case, the slave thread stops and waits for you to clean up the tables manually to bring them into synchrony. *This is not a replication problem. It is a problem of outside interference causing replication to fail.*
2. Run the slave with the `--log-slave-updates` and `--log-bin` options. These options cause the slave to log the updates that it receives from the master into its own binary logs.
3. Save all evidence before resetting the replication state. If we have no information or only sketchy information, it becomes difficult or impossible for us to track down the problem. The evidence you should collect is:
 - All binary logs from the master
 - All binary logs from the slave
 - The output of `SHOW MASTER STATUS` from the master at the time you discovered the problem
 - The output of `SHOW SLAVE STATUS` from the slave at the time you discovered the problem
 - Error logs from the master and the slave
4. Use `mysqlbinlog` to examine the binary logs. The following should be helpful to find the problem statement. `log_pos` and `log_file` are the `Master_Log_File` and `Read_Master_Log_Pos` values from `SHOW SLAVE STATUS`.

```
shell> mysqlbinlog -j log_pos log_file | head
```

After you have collected the evidence for the problem, try to isolate it as a separate test case first. Then enter the problem with as much information as possible into our bugs database using the instructions at [Section 1.8, “How to Report Bugs or Problems”](#).

15.4. Replication Implementation

The basic mechanics of replication is based on the master server keeping track of all changes to your databases (updates, deletes, and so on) in its binary logs. The binary log serves as a written record of each to the database from the moment the database was started. The binary log contains records of all the statements which edit or modify either the database structure or the data that the structure contains. Typically `SELECT` statements are not recorded, as they do not modify the database data or structure.

Each slave that connects to the master receives a copy of the binary log, and executes the events within the binary log. This has the effect of repeating the original statements and changes just as they were made on the master. Tables are created or their structure modified, and data is inserted, deleted and updated according to the statements that were originally executed on the master.

Because each slave is independent, the replaying of the statements in the masters binary log can occur on each slave that is connected to the master. In addition, because each slave only receives a copy of the binary log by requesting it from the master (it pulls the data from the master, rather than the master pushing the data to the slave), the slave is able to read and update the copy of the database at it's own

pace and rate and can start and stop the replication process at will without affecting the master or the slaves ability to update to the latest database status.

For more information on the specifics of the replication implementation, see [Section 15.4.1, “Replication Implementation Details”](#).

Slaves and masters report their status in respect of the replication process regularly so that you can monitor the situation. For information on slave states, see [Section 6.5.5.5, “Replication Slave I/O Thread States”](#), and [Section 6.5.5.6, “Replication Slave SQL Thread States”](#). For master states, see [Section 6.5.5.4, “Replication Master Thread States”](#).

The master binary log is written to a local relay log on the slave before it is processed. The slave also records information about the current position with the master's binary log and the local relayed log. See [Section 15.4.2, “Replication Relay and Status Files”](#).

Databases and tables are updated on the slave according to a set of rules that are applied according to the various configuration options and variables that control statement evaluation. For details on how these rules are applied, see [Section 15.4.3, “How Servers Evaluate Replication Rules”](#).

15.4.1. Replication Implementation Details

MySQL replication capabilities are implemented using three threads (one on the master server and two on the slave). When a [START SLAVE](#) statement is issued on a slave server, the slave creates an I/O thread, which connects to the master and asks it to send the updates recorded in its binary logs. The master creates a thread to send the binary log contents to the slave. This thread can be identified as the [Binlog Dump](#) thread in the output of [SHOW PROCESSLIST](#) on the master. The slave I/O thread reads the updates that the master [Binlog Dump](#) thread sends and copies them to local files, known as *relay logs*, in the slave's data directory. The third thread is the SQL thread, which the slave creates to read the relay logs and to execute the updates they contain.

MySQL Enterprise

For constant monitoring of the status of slaves subscribe to the MySQL Enterprise Monitor. For more information see <http://www.mysql.com/products/enterprise/advisors.html>.

In the preceding description, there are three threads per master/slave connection. A master that has multiple slaves creates one thread for each currently-connected slave, and each slave has its own I/O and SQL threads.

The slave uses two threads so that reading updates from the master and executing them can be separated into two independent tasks. Thus, the task of reading statements is not slowed down if statement execution is slow. For example, if the slave server has not been running for a while, its I/O thread can quickly fetch all the binary log contents from the master when the slave starts, even if the SQL thread lags far behind. If the slave stops before the SQL thread has executed all the fetched statements, the I/O thread has at least fetched everything so that a safe copy of the statements is stored locally in the slave's relay logs, ready for execution the next time that the slave starts. This enables the master server to purge its binary logs sooner because it no longer needs to wait for the slave to fetch their contents.

The [SHOW PROCESSLIST](#) statement provides information that tells you what is happening on the master and on the slave regarding replication. See [Section 6.5.5, “Examining Thread Information”](#), for descriptions of all replicated-related states.

The following example illustrates how the three threads show up in the output from [SHOW PROCESSLIST](#).

On the master server, the output from [SHOW PROCESSLIST](#) looks like this:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
  Id: 2
  User: root
  Host: localhost:32931
  db: NULL
  Command: Binlog Dump
  Time: 94
  State: Has sent all binlog to slave; waiting for binlog to
        be updated
  Info: NULL
```

Here, thread 2 is a [Binlog Dump](#) replication thread for a connected slave. The [State](#) information indicates that all outstanding updates have been sent to the slave and that the master is waiting for more updates to occur. If you see no [Binlog Dump](#) threads on a master server, this means that replication is not running — that is, that no slaves are currently connected.

On the slave server, the output from [SHOW PROCESSLIST](#) looks like this:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
  Id: 10
```

```

User: system user
Host:
db: NULL
Command: Connect
Time: 11
State: Waiting for master to send event
Info: NULL
***** 2. row *****
Id: 11
User: system user
Host:
db: NULL
Command: Connect
Time: 11
State: Has read all relay log; waiting for the slave I/O
      thread to update it
Info: NULL

```

This information indicates that thread 10 is the I/O thread that is communicating with the master server, and thread 11 is the SQL thread that is processing the updates stored in the relay logs. At the time that the `SHOW PROCESSLIST` was run, both threads were idle, waiting for further updates.

The value in the `Time` column can show how late the slave is compared to the master. See [Section 15.3.4, “Replication FAQ”](#).

15.4.2. Replication Relay and Status Files

During replication the MySQL server creates a number of files that are used to hold the relayed binary log from the master, and record information about the current status and location within the relayed log. There are three file types used in the process:

- The *relay log* consists of the events read from the binary log of the master. Events in this binary log are executed on the slave as part of the replication thread.
- The *master.info* file contains the status and current configuration information for the slave's connectivity to the master. The file holds information on the master hostname, login credentials, and the current position within the master's binary log.
- The *relay.info* file holds the status information about the execution point within the slave's relay log files.

The relationship between the three files and the replication process is as follows. The `master.info` file retains the point within the master binary log that has been read from the master. These read events are written to the relay log. The `relay.info` file records the position within the relay log of the statements that have been executed.

15.4.2.1. The Slave Relay Log

By default, relay logs filenames have the form `host_name-relay-bin.nnnnnn`, where `host_name` is the name of the slave server host and `nnnnnn` is a sequence number. Successive relay log files are created using successive sequence numbers, beginning with `000001`. The slave uses an index file to track the relay log files currently in use. The default relay log index filename is `host_name-relay-bin.index`.

By default, the slave server creates relay log files in its data directory. The default filenames can be overridden with the `--relay-log` and `--relay-log-index` server options. See [Section 15.1.3, “Replication Options and Variables”](#).

Relay logs have the same format as binary logs and can be read using `mysqlbinlog`. The SQL thread automatically deletes each relay log file as soon as it has executed all events in the file and no longer needs it. There is no explicit mechanism for deleting relay logs because the SQL thread takes care of doing so. However, `FLUSH LOGS` rotates relay logs, which influences when the SQL thread deletes them.

A slave server creates a new relay log file under the following conditions:

- Each time the I/O thread starts.
- When the logs are flushed; for example, with `FLUSH LOGS` or `mysqladmin flush-logs`.
- When the size of the current relay log file becomes too large. The meaning of “too large” is determined as follows:
 - If the value of `max_relay_log_size` is greater than 0, that is the maximum relay log file size.
 - If the value of `max_relay_log_size` is 0, `max_binlog_size` determines the maximum relay log file size.

15.4.2.2. The Slave Status Files

A slave replication server creates two small files in the data directory. These *status files* are named `master.info` and `relay-log.info` by default. Their names can be changed by using the `--master-info-file` and `--relay-log-info-file` options. See [Section 15.1.3, “Replication Options and Variables”](#).

The two status files contain information like that shown in the output of the `SHOW SLAVE STATUS` statement, which is discussed in [Section 12.6.2, “SQL Statements for Controlling Slave Servers”](#). Because the status files are stored on disk, they survive a slave server's shutdown. The next time the slave starts up, it reads the two files to determine how far it has proceeded in reading binary logs from the master and in processing its own relay logs.

The I/O thread updates the `master.info` file. The following table shows the correspondence between the lines in the file and the columns displayed by `SHOW SLAVE STATUS`.

Line	Status Column	Description
1		Number of lines in the file
2	<code>Master_Log_File</code>	The name of the master binary log currently being read from the master.
3	<code>Read_Master_Log_Pos</code>	The current position within the master binary log that have been read from the master.
4	<code>Master_Host</code>	The hostname of the master.
5	<code>Master_User</code>	The username used to connect to the master.
6	Password (not shown by <code>SHOW SLAVE STATUS</code>)	The password used to connect to the master.
7	<code>Master_Port</code>	The network port used to connect to the master.
8	<code>Connect_Retry</code>	The period (in seconds) that the slave will wait before trying to re-connect to the master.
9	<code>Master_SSL_Allowed</code>	Indicates whether the server supports SSL connections.
10	<code>Master_SSL_CA_File</code>	The file used for the Certificate Authority (CA) certificate.
11	<code>Master_SSL_CA_Path</code>	The path to the Certificate Authority (CA) certificates.
12	<code>Master_SSL_Cert</code>	The name of the SSL certificate file.
13	<code>Master_SSL_Cipher</code>	The name of the cipher in use for the SSL connection.
14	<code>Master_SSL_Key</code>	The name of the SSL key file.
15	<code>Master_SSL_Verify_Server_Cert</code>	Whether to verify the server certificate.

`Master_SSL_Verify_Server_Cert` is present in `master.info` as of MySQL 5.1.18. It is used as described for the `--ssl-verify-server-cert` option in [Section 5.8.7.3, “SSL Command Options”](#).

The SQL thread updates the `relay-log.info` file. The following table shows the correspondence between the lines in the file and the columns displayed by `SHOW SLAVE STATUS`.

Line	Status Column	Description
1	<code>Relay_Log_File</code>	The name of the current relay log file.
2	<code>Relay_Log_Pos</code>	The current position within the relay log file. Events up to this position have been executed on the slave database.
3	<code>Relay_Master_Log_File</code>	The name of the master binary log file from which the events in the relay log file were read.
4	<code>Exec_Master_Log_Pos</code>	The equivalent position within the master's binary log file of events that have already been executed.

The contents of the `relay-log.info` file and the states shown by the `SHOW SLAVE STATES` command may not match if the `relay-log.info` file has not been flushed to disk. Ideally, you should only view `relay-log.info` on a slave that is offline (i.e. `mysqld` is not running). For a running system, `SHOW SLAVE STATUS` should be used.

15.4.3. How Servers Evaluate Replication Rules

If a master server does not write a statement to its binary log, the statement is not replicated. If the server does log the statement, the statement is sent to all slaves and each slave determines whether to execute it or ignore it.

On the master you can control which databases write events to the binary log using the `--binlog-do-db` and `--binlog-ignore-db` options to control binary logging. For a description of the rules that servers use in evaluating these options, see [Section 5.11.4, “The Binary Log”](#). You should not use these options to control the databases and tables that are replicated, instead, use filtering on the slave to control the events that are executed on the slave.

On the slave side, decisions about whether to execute or ignore statements received from the master are made according to the `--replicate-*` options that the slave was started with. (See [Section 15.1.3, “Replication Options and Variables”](#).) The slave evaluates these options using the following procedure, which first checks the database-level options and then the table-level options.

In the simplest case, when there are no `--replicate-*` options, the procedure yields the result that the slave executes all statements that it receives from the master. Otherwise, the result depends on the particular options given. In general, to make it easier to determine what effect an option set will have, it is recommended that you avoid mixing “do” and “ignore” options, or wildcard and non-wildcard options.

Stage 1. Check the database options.

At this stage, the slave checks whether there are any `--replicate-do-db` or `--replicate-ignore-db` options that specify database-specific conditions:

- *No*: Permit the statement and proceed to the table-checking stage.
- *Yes*: Test the options using the same rules as for the `--binlog-do-db` and `--binlog-ignore-db` options to determine whether to permit or ignore the statement. What is the result of the test?
 - *Permit*: Do not execute the statement immediately. Defer the decision and proceed to the table-checking stage.
 - *Ignore*: Ignore the statement and exit.

This stage can permit a statement for further option-checking, or cause it to be ignored. However, statements that are permitted at this stage are not actually executed yet. Instead, they pass to the following stage that checks the table options.

Stage 2. Check the table options.

First, as a preliminary condition, the slave checks whether statement-based replication is enabled. If so and the statement occurs within a stored function, execute the statement and exit. (If row-based replication is enabled, the slave does not know whether a statement occurred within a stored function on the master, so this condition does not apply.)

Next, the slave checks for table options and evaluates them. If the server reaches this point, it executes all statements if there are no table options. If there are “do” table options, the statement must match one of them if it is to be executed; otherwise, it is ignored. If there are any “ignore” options, all statements are executed except those that match any “ignore” option. The following steps describe how this evaluation occurs in more detail.

1. Are there any `--replicate-*-table` options?

- *No*: There are no table restrictions, so all statements match. Execute the statement and exit.
- *Yes*: There are table restrictions. Evaluate the tables to be updated against them. There might be multiple tables to update, so loop through the following steps for each table looking for a matching option. In this case, the behavior depends on whether statement-based replication or row-based replication is enabled:
 - *Statement-based replication*: Proceed to the next step and begin evaluating the table options in the order shown (first the non-wild options, and then the wild options). Only tables that are to be updated are compared to the options. For example, if the statement is `INSERT INTO sales SELECT * FROM prices`, only `sales` is compared to the options). If several tables are to be updated (multiple-table statement), the first table that matches “do” or “ignore” wins. That is, the server checks the first table against the options. If no decision could be made, it checks the second table against the options, and so on.
 - *Row-based replication*: All table row changes are filtered individually. For multiple-table updates, each table is filtered sep-

arately according to the options. Some updates may be executed and some not, depending on the options and the changes to be made. Row-based replication correctly handles cases that would not replicate correctly with statement-based replication, as in this example which assumes that tables in the `foo` database should be replicated:

```
mysql> USE bar;  
mysql> INSERT INTO foo.sometable VALUES (1);
```

2. Are there any `--replicate-do-table` options?
 - *No*: Proceed to the next step.
 - *Yes*: Does the table match any of them?
 - *No*: Proceed to the next step.
 - *Yes*: Execute the statement and exit.
3. Are there any `--replicate-ignore-table` options?
 - *No*: Proceed to the next step.
 - *Yes*: Does the table match any of them?
 - *No*: Proceed to the next step.
 - *Yes*: Ignore the statement and exit.
4. Are there any `--replicate-wild-do-table` options?
 - *No*: Proceed to the next step.
 - *Yes*: Does the table match any of them?
 - *No*: Proceed to the next step.
 - *Yes*: Execute the statement and exit.
5. Are there any `--replicate-wild-ignore-table` options?
 - *No*: Proceed to the next step.
 - *Yes*: Does the table match any of them?
 - *No*: Proceed to the next step.
 - *Yes*: Ignore the statement and exit.
6. No `--replicate-*-table` option was matched. Is there another table to test against these options?
 - *No*: We have now tested all tables to be updated and could not match any option. Are there `--replicate-do-table` or `--replicate-wild-do-table` options?
 - *No*: There were no “do” table options, so no explicit “do” match is required. Execute the statement and exit.
 - *Yes*: There were “do” table options, so the statement is executed only with an explicit match to one of them. Ignore the statement and exit.
 - *Yes*: Loop.

Examples:

- No `--replicate-*` options at all

The slave executes all statements that it receives from the master.

- `--replicate-*-db` options, but no table options

The slave permits or ignores statements using the database options. Then it executes all statements permitted by those options because there are no table restrictions.

- `--replicate-*-table` options, but no database options

All statements are permitted at the database-checking stage because there are no database conditions. The slave executes or ignores statements based on the table options.

- A mix of database and table options

The slave permits or ignores statements using the database options. Then it evaluates all statements permitted by those options according to the table options. In some cases, this process can yield what might seem a counterintuitive result. Consider the following set of options:

```
[mysqld]  
replicate-do-db      = db1  
replicate-do-table   = db2.mytbl2
```

Suppose that `db1` is the default database and the slave receives this statement:

```
INSERT INTO mytbl1 VALUES(1,2,3);
```

The database is `db1`, which matches the `--replicate-do-db` option at the database-checking stage. The algorithm then proceeds to the table-checking stage. If there were no table options, the statement would be executed. However, because the options include a “do” table option, the statement must match if it is to be executed. The statement does not match, so it is ignored. (The same would happen for any table in `db1`.)

Chapter 16. MySQL Cluster

MySQL Cluster is a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. It uses the **NDB Cluster** storage engine to enable running several MySQL servers in a cluster. This storage engine is available in MySQL 5.1 binary releases and in RPMs compatible with most modern Linux distributions.

Note

Binary releases and RPMs are not available for MySQL Cluster 5.1 Carrier Grade Edition, which must be built from source.

MySQL Cluster is currently available and supported on a number of platforms, including Linux, Solaris, Mac OS X, HP-UX, and other Unix-style operating systems on a variety of hardware. For exact levels of support available for on specific combinations of operating system versions, operating system distributions, and hardware platforms, please refer to the [Cluster Supported Platforms list](#) maintained by the MySQL Support Team on the MySQL AB Web site.

MySQL Cluster is *not* currently supported on Microsoft Windows. We are working to make Cluster available on all operating systems supported by MySQL, including Windows, and will update the information provided here as this work continues.

This chapter represents a work in progress, and its contents are subject to revision as MySQL Cluster continues to evolve. Additional information regarding MySQL Cluster can be found on the MySQL AB Web site at <http://www.mysql.com/products/cluster/>.

Information about MySQL MySQL Cluster 5.1 Carrier Grade Edition can be found in [Section 16.2, “MySQL Cluster 5.1 Carrier Grade Edition”](#) as well as on the MySQL AB web site at <http://www.mysql.com/products/database/clustercge/>.

Additional resources. More information may be found in the following places:

- Answers to some commonly asked questions about Cluster may be found in the [Section A.10, “MySQL 5.1 FAQ — MySQL Cluster”](#).
- The MySQL Cluster mailing list: <http://lists.mysql.com/cluster>.
- The MySQL Cluster Forum: <http://forums.mysql.com/list.php?25>.
- Many MySQL Cluster users and some of the MySQL Cluster developers blog about their experiences with Cluster, and make feeds of these available through [PlanetMySQL](#).
- If you are new to MySQL Cluster, you may find our Developer Zone article [How to set up a MySQL Cluster for two servers](#) to be helpful.

16.1. MySQL Cluster Overview

MySQL Cluster is a technology that enables clustering of in-memory databases in a shared-nothing system. The shared-nothing architecture allows the system to work with very inexpensive hardware, and with a minimum of specific requirements for hardware or software.

MySQL Cluster is designed not to have any single point of failure. For this reason, each component is expected to have its own memory and disk, and the use of shared storage mechanisms such as network shares, network filesystems, and SANs is not recommended or supported.

MySQL Cluster integrates the standard MySQL server with an in-memory clustered storage engine called **NDB**. In our documentation, the term **NDB** refers to the part of the setup that is specific to the storage engine, whereas “MySQL Cluster” refers to the combination of MySQL and the **NDB** storage engine.

A MySQL Cluster consists of a set of computers, each running a one or more processes which may include a MySQL server, a data node, a management server, and (possibly) a specialized data access programs. The relationship of these components in a cluster is shown here:

All these programs work together to form a MySQL Cluster. When data is stored in the **NDB Cluster** storage engine, the tables are stored in the data nodes. Such tables are directly accessible from all other MySQL servers in the cluster. Thus, in a payroll application storing data in a cluster, if one application updates the salary of an employee, all other MySQL servers that query this data can see this change immediately.

The data stored in the data nodes for MySQL Cluster can be mirrored; the cluster can handle failures of individual data nodes with no other impact than that a small number of transactions are aborted due to losing the transaction state. Because transactional applications are expected to handle transaction failure, this should not be a source of problems.

16.1.1. MySQL Cluster Core Concepts

NDB is an in-memory storage engine offering high-availability and data-persistence features.

The **NDB** storage engine can be configured with a range of failover and load-balancing options, but it is easiest to start with the storage engine at the cluster level. MySQL Cluster's **NDB** storage engine contains a complete set of data, dependent only on other data within the cluster itself.

The cluster portion of MySQL Cluster is currently configured independently of the MySQL servers. In a MySQL Cluster, each part of the cluster is considered to be a *node*.

Note

In many contexts, the term “node” is used to indicate a computer, but when discussing MySQL Cluster it means a *process*. It is possible to run any number of nodes on a single computer, for which we use the term *cluster host*.

(However, it should be noted MySQL does not currently support the use of multiple data nodes on a single computer in a production setting. See [Section 16.13.10, “Limitations Relating to Multiple Cluster Nodes”](#).)

There are three types of cluster nodes, and in a minimal MySQL Cluster configuration, there will be at least three nodes, one of each of these types:

- **Management node** (MGM node): The role of this type of node is to manage the other nodes within the MySQL Cluster, performing such functions as providing configuration data, starting and stopping nodes, running backup, and so forth. Because this node type manages the configuration of the other nodes, a node of this type should be started first, before any other node. An MGM node is started with the command `ndb_mgmd`.
- **Data node**: This type of node stores cluster data. There are as many data nodes as there are replicas, times the number of fragments. For example, with two replicas, each having two fragments, you will need four data nodes. It is not necessary to have more than one replica. A data node is started with the command `ndbd`.
- **SQL node**: This is a node that accesses the cluster data. In the case of MySQL Cluster, an SQL node is a traditional MySQL server that uses the **NDB Cluster** storage engine. An SQL node is typically started with the command `mysqld --ndbcluster` or by using `mysqld` with the `ndbcluster` option added to `my.cnf`.

An SQL node is actually just a specialised type of *API node*, which designates any application which accesses Cluster data. One example of an API node is the `ndb_restore` utility that is used to restore a cluster backup. It is possible to write such applications using the **NDB API**.

Important

It is not realistic to expect to employ a three-node setup in a production environment. Such a configuration provides no redundancy; in order to benefit from MySQL Cluster's high-availability features, you must use multiple data and SQL nodes. The use of multiple management nodes is also highly recommended.

For a brief introduction to the relationships between nodes, node groups, replicas, and partitions in MySQL Cluster, see [Section 16.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”](#).

Configuration of a cluster involves configuring each individual node in the cluster and setting up individual communication links between nodes. MySQL Cluster is currently designed with the intention that data nodes are homogeneous in terms of processor power, memory space, and bandwidth. In addition, to provide a single point of configuration, all configuration data for the cluster as a whole is located in one configuration file.

The management server (MGM node) manages the cluster configuration file and the cluster log. Each node in the cluster retrieves the configuration data from the management server, and so requires a way to determine where the management server resides. When interesting events occur in the data nodes, the nodes transfer information about these events to the management server, which then writes the information to the cluster log.

In addition, there can be any number of cluster client processes or applications. These are of two types:

- **Standard MySQL clients.** These are no different for MySQL Cluster than they are for standard (non-Cluster) MySQL. In other words, MySQL Cluster can be accessed from existing MySQL applications written in PHP, Perl, C, C++, Java, Python, Ruby, and so on.
- **Management clients.** These clients connect to the management server and provide commands for starting and stopping nodes gracefully, starting and stopping message tracing (debug versions only), showing node versions and status, starting and stopping backups, and so on.

16.1.2. MySQL Cluster Nodes, Node Groups, Replicas, and Partitions

This section discusses the manner in which MySQL Cluster divides and duplicates data for storage.

Central to an understanding of this topic are the following concepts, listed here with brief definitions:

- **(Data) Node.** An `ndbd` process, which stores a *replica* —that is, a copy of the *partition* (see below) assigned to the node group of which the node is a member.

Each data node should be located on a separate computer. While it is also possible to host multiple `ndbd` processes on a single computer, such a configuration is not supported.

It is common for the terms “node” and “data node” to be used interchangeably when referring to an `ndbd` process; where mentioned, management (MGM) nodes (`ndb_mgmd` processes) and SQL nodes (`mysqld` processes) are specified as such in this discussion.

- **Node Group.** A node group consists of one or more nodes, and stores partitions, or sets of *replicas* (see next item).

Note

All node groups in a cluster must have the same number of nodes.

- **Partition.** This is a portion of the data stored by the cluster. There are as many cluster partitions as nodes participating in the cluster. Each node is responsible for keeping at least one copy of any partitions assigned to it (that is, at least one replica) available to the cluster.

A replica belongs entirely to a single node; a node can (and usually does) store several replicas.

- **Replica.** This is a copy of a cluster partition. Each node in a node group stores a replica. Also sometimes known as a *partition replica*. The number of replicas is equal to the number of nodes per node group.

The following diagram illustrates a MySQL Cluster with four data nodes, arranged in two node groups of two nodes each; nodes 1 and 2 belong to node group 0, and nodes 3 and 4 belong to node group 1. Note that only data (**ndbd**) nodes are shown here; although a working cluster requires an **ndb_mgm** process for cluster management and at least one SQL node to access the data stored by the cluster, these have been omitted in the figure for clarity.

The data stored by the cluster is divided into four partitions, numbered 0, 1, 2, and 3. Each partition is stored — in multiple copies — on the same node group. Partitions are stored on alternate node groups:

- Partition 0 is stored on node group 0; a *primary replica* (primary copy) is stored on node 1, and a *backup replica* (backup copy of the partition) is stored on node 2.
- Partition 1 is stored on the other node group (node group 1); this partition's primary replica is on node 3, and its backup replica is on node 4.
- Partition 2 is stored on node group 0. However, the placing of its two replicas is reversed from that of Partition 0; for Partition 2, the primary replica is stored on node 2, and the backup on node 1.
- Partition 3 is stored on node group 1, and the placement of its two replicas are reversed from those of partition 1. That is, its primary

replica is located on node 4, with the backup on node 3.

What this means regarding the continued operation of a MySQL Cluster is this: so long as each node group participating in the cluster has at least one node operating, the cluster has a complete copy of all data and remains viable. This is illustrated in the next diagram.

In this example, where the cluster consists of two node groups of two nodes each, any combination of at least one node in node group 0 and at least one node in node group 1 is sufficient to keep the cluster “alive” (indicated by arrows in the diagram). However, if *both* nodes from *either* node group fail, the remaining two nodes are not sufficient (shown by the arrows marked out with an X); in either case, the cluster has lost an entire partition and so can no longer provide access to a complete set of all cluster data.

16.2. MySQL Cluster 5.1 Carrier Grade Edition

MySQL Cluster 5.1 Carrier Grade Edition is a branch of MySQL 5.1 using advanced versions of the [NDB](#) storage engine and [NDB](#) API, created as a direct response to customer needs. It is intended for use in the telecommunications industry, and is available in binary and source form to commercial customers.

Two development trees can also be accessed via <http://mysql.bkbits.net/>:

- [mysql-5.1-telco](#)
- [mysql-5.1-telco-6.1](#)

Important

This chapter of the MySQL Manual covers both MySQL 5.1 and MySQL Cluster 5.1 Carrier Grade Edition.

Information which applies to MySQL Cluster 5.1 Carrier Grade Edition releases but not to mainline 5.1 releases is indicated with a warning such as this one:

MySQL Cluster 5.1 Carrier Grade Edition

The following information applies to users of MySQL Cluster 5.1 Carrier Grade Edition only. For more information about MySQL Cluster 5.1 Carrier Grade Edition, see Section 16.2, “MySQL Cluster 5.1 Carrier Grade Edition”.

Information which applies to mainline MySQL 5.1 releases but not to MySQL Cluster 5.1 Carrier Grade Edition releases is indicated with a warning such as this one:

MySQL Cluster 5.1 Carrier Grade Edition

The following information does not apply to users of MySQL Cluster 5.1 Carrier Grade Edition. For more information about MySQL Cluster 5.1 Carrier Grade Edition, see Section 16.2, “MySQL Cluster 5.1 Carrier Grade Edition”.

(Similar warnings are displayed where appropriate in [The MySQL Cluster API Developers' Guide](#).)

Currently, both the `ndb-6.1.x` and `ndb-6.2.x` series are under active development, with the `ndb-6.1.x` series intended for use by telecommunications customers and `ndb-6.2.x` intended for testing purposes. Differences between the mainline MySQL 5.1 series and MySQL Cluster 5.1 Carrier Grade Edition are highlighted in [Section 16.2.1, “Major Differences Between MySQL 5.1 and MySQL Cluster 5.1 Carrier Grade Edition”](#).

MySQL Cluster 5.1 Carrier Grade Edition versioning. MySQL Cluster 5.1 Carrier Grade Edition — sometimes also referred to as “CGE” — follows a somewhat different release pattern from the mainline MySQL 5.1 Cluster series of releases. Each MySQL Cluster 5.1 Carrier Grade Edition release is identified by a two-part version string which identifies the mainline MySQL version from which the CGE release was branched and the version of the **NDB** storage engine used. For example, the first CGE release was `mysql-5.1.14-ndb-6.1.0` (shown as “MySQL 5.1.14-ndb-6.1.0” in this Manual). The version string tells us that this version:

- Derives from MySQL 5.1.14, and contains all feature enhancement and bugfixes from MySQL 5.1, up to and including MySQL 5.1.14.
- Uses version 6.1.0 of the **NDB** storage engine.

A listing of available 5.1.15-ndb-6.1.6-beta releases for both the `ndb-6.1.x` and the `ndb-6.1.x` series can be found in [Section 16.2.2, “MySQL Cluster 5.1 Carrier Grade Edition Releases”](#).

Additional information about obtaining MySQL Cluster 5.1 Carrier Grade Edition binaries can be found on the MySQL AB web site at <http://www.mysql.com/products/database/clustercge/>, or by contacting [<sales@mysql.com>](mailto:sales@mysql.com).

16.2.1. Major Differences Between MySQL 5.1 and MySQL Cluster 5.1 Carrier Grade Edition

This section lists the most prominent feature differences between mainline releases of MySQL 5.1 and MySQL Cluster 5.1 Carrier Grade Edition releases.

Note

MySQL Cluster 5.1 Carrier Grade Edition also fixes many MySQL Cluster bugs before the fixes appear in MySQL 5.1. The MySQL Cluster 5.1 Carrier Grade Edition changelogs has complete listings of these — see [Section 16.2.2, “MySQL Cluster 5.1 Carrier Grade Edition Releases”](#).

ndb-6.1.x branch.

- Enhanced backup status reporting, aided in part by the introduction of a `BackupReportFrequency` configuration parameter (MySQL 5.1.14-ndb-6.1.0).
- Maximum number of all nodes in a cluster increased to 255 (MySQL 5.1.14-ndb-6.1.1).

- Addition of the `NDB API Dictionary::listEvents()` method (MySQL 5.1.15-ndb-6.1.3).
- Ability to disable arbitration, by setting `ArbitrationRank=0` on all nodes (MySQL 5.1.15-ndb-6.1.3).
- Inclusion of the `ndb_redo_log_reader` utility in the default build (MySQL 5.1.15-ndb-6.1.3).
- New methods of the `Ndb_cluster_connection` class, making it possible to iterate over all existing `Ndb` objects (MySQL 5.1.15-ndb-6.1.4).
- `--ndb-wait-connected` option for `mysqld`, causing `mysqld` wait a specified amount of time to be connected to the cluster before starting to accept client connections (MySQL 5.1.15-ndb-6.1.4).
- Improved data node memory allocation (MySQL 5.1.15-ndb-6.1.4).
- Ability to pipe output of `ndb_restore` to CSV file (MySQL 5.1.15-ndb-6.1.5).
- A new `FragmentLogFileSize` configuration parameter makes it possible to set the size of redo log files (MySQL 5.1.15-ndb-6.1.11).
- `MaxAllocate` configuration parameter makes it possible to set the maximum size of the allocation unit used for table memory (MySQL 5.1.15-ndb-6.1.12).
- New management client `DUMP` commands providing help with tracking transactions, scan operations, and locks (MySQL 5.1.15-ndb-6.1.12).
- Improvements in backups of Disk Data tables resulted in a 10 to 15% increase in backup speed of Disk Data tables (MySQL 5.1.15-ndb-6.1.13).
- Batching of updates on cluster replication slaves, enabled using the `--slave-allow-batching` option for `mysqld` (MySQL 5.1.15-ndb-6.1.17).

ndb-6.2.x branch. The following improvements are available in ndb-6.2.x releases:

- Multiple cluster connections by a single MySQL server using the `--ndb-cluster-connection-pool` startup option for `mysqld` (MySQL 5.1.18-ndb-6.2.2).
- New management client `DUMP` commands providing help with tracking transactions, scan operations, and locks (MySQL 5.1.18-ndb-6.2.2).
- The addition of the `NdbRecord` interface and handler for the `NDB` API (MySQL 5.1.19-ndb-6.2.3).
- Enhanced backup status reporting, aided in part by the introduction of a `BackupReportFrequency` configuration parameter as well as a new management client command `REPORT BackupStatus` (MySQL 5.1.19-ndb-6.2.3).
- In-progress status reporting by `ndb_restore` (MySQL 5.1.19-ndb-6.2.3).
- Batching of updates on cluster replication slaves, enabled using the `--slave-allow-batching` option for `mysqld` (MySQL 5.1.19-ndb-6.2.3).
- Improved memory allocation in the `NDB` kernel (MySQL 5.1.19-ndb-6.2.3).
- Improvements in backups of Disk Data tables resulted in a 10 to 15% increase in backup speed of Disk Data tables (MySQL 5.1.19-ndb-6.2.3).
- `MaxAllocate` configuration parameter makes it possible to set the maximum size of the allocation unit used for table memory (MySQL 5.1.19-ndb-6.2.3).
- The ability to control whether fixed-width or variable-width storage is used for a given column of an `NDB` table by means of the `COLUMN_FORMAT` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement. In addition, the ability to control whether a given column of an `NDB` table is stored in memory or on disk, using the `STORAGE` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement. (MySQL 5.1.19-ndb-6.2.5)
- The `--bind-address` cluster management server startup option makes it possible to restrict management client connections to `ndb_mgmd` to a single host and port. (MySQL 5.1.19-ndb-6.2.5)

- Due to a change in the protocol for handling of global checkpoints (GCPs handled in this manner sometimes being referred to as “micro-GCPs”), it is now possible to control how often the GCI number is updated, and how often global checkpoints are written to disk, using the [TimeBetweenEpochs](#) configuration parameter. This improves the reliability and performance of MySQL Cluster Replication. (MySQL 5.1.22-ndb-6.2.5)

ndb-6.3.x branch. The following improvements are available in ndb-6.3.x releases:

- Implementation of conflict resolution for use in multi-master replication (MySQL 5.1.19-ndb-6.3.0).
- The ability to control whether fixed-width or variable-width storage is used for a given column of an **NDB** table by means of the [COLUMN_FORMAT](#) specifier as part of the column's definition in a [CREATE TABLE](#) or [ALTER TABLE](#) statement. In addition, the ability to control whether a given column of an **NDB** table is stored in memory or on disk, using the [STORAGE](#) specifier as part of the column's definition in a [CREATE TABLE](#) or [ALTER TABLE](#) statement. (MySQL 5.1.22-ndb-6.3.2)
- The [--bind-address](#) cluster management server startup option makes it possible to restrict management client connections to [ndb_mgmd](#) to a single host and port. (MySQL 5.1.22-ndb-6.3.2)
- Due to a change in the protocol for handling of global checkpoints (GCPs handled in this manner sometimes being referred to as “micro-GCPs”), it is now possible to control how often the GCI number is updated, and how often global checkpoints are written to disk, using the [TimeBetweenEpochs](#) configuration parameter. This improves the reliability and performance of MySQL Cluster Replication. (MySQL 5.1.22-ndb-6.3.2)

More detailed information can be found in the changelogs for individual MySQL Cluster 5.1 Carrier Grade Edition releases; see [Section 16.2.2, “MySQL Cluster 5.1 Carrier Grade Edition Releases”](#), for a current changelog listing.

16.2.2. MySQL Cluster 5.1 Carrier Grade Edition Releases

Changelogs and source code download locations for MySQL Cluster 5.1 Carrier Grade Edition releases may be found in [Section C.1, “Changes in release 5.1.x \(Development\)”](#); these are grouped together according to the mainline MySQL 5.1 version from which they derive, as shown in the list that follows:

- [Section C.1.16, “Changes in MySQL 5.1.14 Carrier Grade Edition”](#):

Includes [Section C.1.16.1, “Changes in release MySQL 5.1.14-ndb-6.1.0-beta \(20 December 2006\)”](#).

This release includes all feature enhancements and bugfixes made in MySQL 5.1 up to and including the 5.1.14 release.

- [Section C.1.14, “Changes in MySQL 5.1.15 Carrier Grade Edition”](#):

Includes these changelogs:

- [Section C.1.14.19, “Changes in release MySQL 5.1.15-ndb-6.1.1-beta \(01 February 2007\)”](#)
- [Section C.1.14.18, “Changes in release MySQL 5.1.15-ndb-6.1.2-beta \(07 February 2007\)”](#)
- [Section C.1.14.17, “Changes in release MySQL 5.1.15-ndb-6.1.3-beta \(25 February 2007\)”](#)
- [Section C.1.14.16, “Changes in release MySQL 5.1.15-ndb-6.1.4-beta \(09 March 2007 - testing only\)”](#)
- [Section C.1.14.15, “Changes in release MySQL 5.1.15-ndb-6.1.5-beta \(15 March 2007\)”](#)
- [Section C.1.14.14, “Changes in release MySQL 5.1.15-ndb-6.1.6-beta \(Not released\)”](#)
- [Section C.1.14.13, “Changes in release MySQL 5.1.15-ndb-6.1.7-beta \(Released 05 May 2007\)”](#)
- [Section C.1.14.12, “Changes in release MySQL 5.1.15-ndb-6.1.8-beta \(Released 05 May 2007\)”](#)
- [Section C.1.14.11, “Changes in release MySQL 5.1.15-ndb-6.1.9-beta \(Released 24 May 2007\)”](#)
- [Section C.1.14.10, “Changes in release MySQL 5.1.15-ndb-6.1.10-beta \(Released 30 May 2007\)”](#)
- [Section C.1.14.9, “Changes in release MySQL 5.1.15-ndb-6.1.11-beta \(Released 06 June 2007\)”](#)

- [Section C.1.14.8, “Changes in release MySQL 5.1.15-ndb-6.1.12-beta \(Released 13 June 2007\)”](#)
- [Section C.1.14.7, “Changes in release MySQL 5.1.15-ndb-6.1.13-beta \(Released 15 June 2007\)”](#)
- [Section C.1.14.6, “Changes in release MySQL 5.1.15-ndb-6.1.14-beta \(Released 19 June 2007\)”](#)
- [Section C.1.14.5, “Changes in release MySQL 5.1.15-ndb-6.1.15-beta \(Released 20 June 2007\)”](#)
- [Section C.1.14.4, “Changes in release MySQL 5.1.15-ndb-6.1.16-beta \(Released 29 June 2007\)”](#)
- [Section C.1.14.3, “Changes in release MySQL 5.1.15-ndb-6.1.17-beta \(Released 03 July 2007\)”](#)

These releases include all feature enhancements and bugfixes made in MySQL 5.1 up to and including 5.1.15, as well as those enhancements specific to MySQL Cluster 5.1 Carrier Grade Edition made in MySQL-5.1.14-ndb-6.1.0.

- [Section C.1.12, “Changes in MySQL 5.1.16 Carrier Grade Edition”](#):

Includes [Section C.1.12.1, “Changes in release MySQL 5.1.16-ndb-6.2.0-beta \(03 March 2007\)”](#).

This release includes all feature enhancements and bugfixes made in MySQL 5.1 up to and including 5.1.16, as well as those enhancements specific to MySQL Cluster 5.1 Carrier Grade Edition that were made in ndb-6.1.x releases.

- [Section C.1.9, “Changes in MySQL 5.1.18 Carrier Grade Edition”](#):

Includes these changelogs:

- [Section C.1.9.2, “Changes in release MySQL 5.1.18-ndb-6.2.1-beta \(Released 30 April 2007\)”](#) and
- [Section C.1.9.1, “Changes in release MySQL 5.1.18-ndb-6.2.2-beta \(07 May 2007\)”](#).

These releases include all feature enhancements and bugfixes made in MySQL 5.1 up to and including 5.1.18, as well as those enhancements specific to MySQL Cluster 5.1 Carrier Grade Edition that were made in ndb-6.2.1 and ndb-6.2.2.

Note

MySQL 5.1.18-ndb-6.2.1 was withdrawn after release, and is no longer available for download.

- [Section C.1.7, “Changes in MySQL 5.1.19 Carrier Grade Edition”](#):

Includes these changelogs:

- [Section C.1.7.4, “Changes in release MySQL 5.1.19-ndb-6.2.3-beta \(02 July 2007\)”](#)
- [Section C.1.7.3, “Changes in release MySQL 5.1.19-ndb-6.2.4-beta \(04 July 2007\)”](#)
- [Section C.1.7.2, “Changes in release MySQL 5.1.19-ndb-6.3.0-beta \(02 July 2007\)”](#)
- [Section C.1.7.1, “Changes in release MySQL 5.1.19-ndb-6.3.1-beta \(04 July 2007\)”](#)

These releases include all feature enhancements and bugfixes made in MySQL 5.1 up to and including 5.1.19, as well as those enhancements specific to MySQL Cluster 5.1 Carrier Grade Edition that were made in ndb-6.2.x releases beginning with MySQL 5.1.19-ndb-6.2.3, as well as those that were made in ndb-6.2.1 and ndb-6.2.2.

- [Section C.1.3, “Changes in MySQL 5.1.20 Carrier Grade Edition”](#):

Includes these changelogs:

- [Section C.1.3.3, “Changes in release MySQL 5.1.22-ndb-6.2.5-beta \(06 September 2007\)”](#)
- [Section C.1.3.2, “Changes in release MySQL 5.1.22-ndb-6.2.6-beta \(Not yet released\)”](#)
- [Section C.1.3.1, “Changes in release MySQL 5.1.22-ndb-6.3.2-beta \(Not yet released\)”](#)

These releases include all feature enhancements and bugfixes made in MySQL 5.1 up to and including 5.1.22. MySQL 5.1.22-ndb-6.2.5 and later ndb-6.2.x releases based on MySQL 5.1.22 include those enhancements made in MySQL 5.1.18-ndb-6.2.1, MySQL 5.1.18-ndb-6.2.2, MySQL 5.1.19-ndb-6.2.3, and MySQL 5.1.19-ndb-6.2.4; MySQL 5.1.22-based ndb-

6.3.x releases include those enhancements made in MySQL 5.1.19-ndb-6.3.0 and MySQL 5.1.19-ndb-6.3.1.

Each of the MySQL Cluster 5.1 Carrier Grade Edition includes enhancements to the [NDB](#) storage engine that do not appear in the mainline MySQL 5.1 tree. We plan to port these to MySQL 5.1 or later mainline MySQL releases at some point in the future.

Some fixes may be listed more than once in [Section C.1, “Changes in release 5.1.x \(Development\)”](#), due to the fact that they were applied first in MySQL Cluster 5.1 Carrier Grade Edition and then ported to MySQL 5.1, because they were applied in more than one branch of MySQL Cluster 5.1 Carrier Grade Edition, or both.

Since all bugfixes applied in MySQL Cluster 5.1 Carrier Grade Edition relate to MySQL Cluster, changelog entries for CGE releases are not prefixed with “[NDB Cluster:](#)” as MySQL Cluster bugfixes in mainline MySQL 5.1 are.

16.3. Simple Multi-Computer How-To

This section is a “How-To” that describes the basics for how to plan, install, configure, and run a MySQL Cluster. Whereas the examples in [Section 16.4, “MySQL Cluster Configuration”](#) provide more in-depth information on a variety of clustering options and configuration, the result of following the guidelines and procedures outlined here should be a usable MySQL Cluster which meets the *minimum* requirements for availability and safeguarding of data.

This section covers hardware and software requirements; networking issues; installation of MySQL Cluster; configuration issues; starting, stopping, and restarting the cluster; loading of a sample database; and performing queries.

Basic assumptions. This How-To makes the following assumptions:

1. The cluster setup has four nodes, each on a separate host, and each with a fixed network address on a typical Ethernet as shown here:

Node	IP Address
Management (MGM) node	192.168.0.10
MySQL server (SQL) node	192.168.0.20
Data (NDBD) node "A"	192.168.0.30
Data (NDBD) node "B"	192.168.0.40

This may be made clearer in the following diagram:

In the interest of simplicity (and reliability), this How-To uses only numeric IP addresses. However, if DNS resolution is available on your network, it is possible to use hostnames in lieu of IP addresses in configuring Cluster. Alternatively, you can use the `/etc/hosts` file or your operating system's equivalent for providing a means to do host lookup if such is available.

Note

A common problem when trying to use hostnames for Cluster nodes arises because of the way in which some operating systems (including some Linux distributions) set up the system's own hostname in the `/etc/hosts` during installation. Consider two machines with the hostnames `ndb1` and `ndb2`, both in the `cluster` network domain. Red Hat Linux (including some derivatives such as CentOS and Fedora) places the following entries in these machines' `/etc/hosts` files:

```
# ndb1 /etc/hosts:
127.0.0.1 ndb1.cluster ndb1 localhost.localdomain localhost
```

```
# ndb2 /etc/hosts:
127.0.0.1 ndb2.cluster ndb2 localhost.localdomain localhost
```

SuSE Linux (including OpenSuSE) places these entries in the machines' `/etc/hosts` files:

```
# ndb1 /etc/hosts:
127.0.0.1 localhost
127.0.0.2 ndb1.cluster ndb1
```

```
# ndb2 /etc/hosts:
127.0.0.1 localhost
127.0.0.2 ndb2.cluster ndb2
```

In both instances, `ndb1` routes `ndb1.cluster` to a loopback IP address, but gets a public IP address from DNS for `ndb2.cluster`, while `ndb2` routes `ndb2.cluster` to a loopback address and obtains a public address for `ndb1.cluster`. The result is that each data node connects to the management server, but cannot tell when any other data nodes have connected, and so the data nodes appear to hang while starting.

You should also be aware that you cannot mix `localhost` and other hostnames or IP addresses in `config.ini`. For these reasons, the solution in such cases (other than to use IP addresses for all `config.ini` `HostName` entries) is to remove the fully qualified hostnames from `/etc/hosts` and use these in `config.ini` for all cluster hosts.

- Each host in our scenario is an Intel-based desktop PC running a common, generic Linux distribution installed to disk in a standard configuration, and running no unnecessary services. The core OS with standard TCP/IP networking capabilities should be sufficient. Also for the sake of simplicity, we also assume that the filesystems on all hosts are set up identically. In the event that they are not, you will need to adapt these instructions accordingly.
- Standard 100 Mbps or 1 gigabit Ethernet cards are installed on each machine, along with the proper drivers for the cards, and that all four hosts are connected via a standard-issue Ethernet networking appliance such as a switch. (All machines should use network cards with the same throughput. That is, all four machines in the cluster should have 100 Mbps cards *or* all four machines should have 1 Gbps cards.) MySQL Cluster will work in a 100 Mbps network; however, gigabit Ethernet will provide better performance.

Note that MySQL Cluster is *not* intended for use in a network for which throughput is less than 100 Mbps. For this reason (among others), attempting to run a MySQL Cluster over a public network such as the Internet is not likely to be successful, and is not recommended.

- For our sample data, we will use the `world` database which is available for download from the MySQL AB Web site. As this database takes up a relatively small amount of space, we assume that each machine has 256MB RAM, which should be sufficient for running the operating system, host NDB process, and (for the data nodes) for storing the database.

Although we refer to a Linux operating system in this How-To, the instructions and procedures that we provide here should be easily adaptable to other supported operating systems. We also assume that you already know how to perform a minimal installation and configuration of the operating system with networking capability, or that you are able to obtain assistance in this elsewhere if needed.

We discuss MySQL Cluster hardware, software, and networking requirements in somewhat greater detail in the next section. (See [Section 16.3.1, “Hardware, Software, and Networking”](#).)

16.3.1. Hardware, Software, and Networking

One of the strengths of MySQL Cluster is that it can be run on commodity hardware and has no unusual requirements in this regard, other than for large amounts of RAM, due to the fact that all live data storage is done in memory. (Note that this is not the case with Disk Data tables — see [Section 16.11, “MySQL Cluster Disk Data Tables”](#), for more information about these.) Naturally, multiple and faster CPUs will enhance performance. Memory requirements for other Cluster processes are relatively small.

The software requirements for Cluster are also modest. Host operating systems do not require any unusual modules, services, applications, or configuration to support MySQL Cluster. For supported operating systems, a standard installation should be sufficient. The MySQL software requirements are simple: all that is needed is a production release of MySQL 5.1 to have Cluster support. It is not necessary to compile MySQL yourself merely to be able to use Cluster. In this How-To, we assume that you are using the server binary appropriate to your operating system, available via the MySQL software downloads page at <http://dev.mysql.com/downloads/>.

For inter-node communication, Cluster supports TCP/IP networking in any standard topology, and the minimum expected for each host is a standard 100 Mbps Ethernet card, plus a switch, hub, or router to provide network connectivity for the cluster as a whole. We strongly recommend that a MySQL Cluster be run on its own subnet which is not shared with non-Cluster machines for the following reasons:

- Security.** Communications between Cluster nodes are not encrypted or shielded in any way. The only means of protecting transmissions within a MySQL Cluster is to run your Cluster on a protected network. If you intend to use MySQL Cluster for Web applications, the cluster should definitely reside behind your firewall and not in your network's De-Militarized Zone (DMZ) or elsewhere.
- Efficiency.** Setting up a MySQL Cluster on a private or protected network allows the cluster to make exclusive use of bandwidth between cluster hosts. Using a separate switch for your MySQL Cluster not only helps protect against unauthorized access to Cluster data, it also ensures that Cluster nodes are shielded from interference caused by transmissions between other computers on the network. For enhanced reliability, you can use dual switches and dual cards to remove the network as a single point of failure; many device drivers support failover for such communication links.

It is also possible to use the high-speed Scalable Coherent Interface (SCI) with MySQL Cluster, but this is not a requirement. See [Section 16.12, “Using High-Speed Interconnects with MySQL Cluster”](#), for more about this protocol and its use with MySQL Cluster.

16.3.2. Multi-Computer Installation

Each MySQL Cluster host computer running data or SQL nodes must have installed on it a MySQL server binary. For management nodes, it is not necessary to install the MySQL server binary, but you do have to install the MGM server daemon (`ndb_mgmd`). It is also a good idea to install the management client (`ndb_mgm`) on the management server host. This section covers the steps necessary to install the correct binaries for each type of Cluster node.

MySQL AB provides precompiled binaries that support Cluster, and there is generally no need to compile these yourself. Therefore, the first step in the installation process for each cluster host is to download the file `mysql-5.1.21-beta-pc-linux-gnu-i686.tar.gz` from the [MySQL downloads area](#). We assume that you have placed it in each machine's `/var/tmp` directory. (If you do require a custom binary, see [Section 2.9.3, “Installing from the Development Source Tree”](#).)

MySQL Cluster 5.1 Carrier Grade Edition

The following information does not apply to users of MySQL Cluster 5.1 Carrier Grade Edition. For more information about MySQL Cluster 5.1 Carrier Grade Edition, see [Section 16.2, “MySQL Cluster 5.1 Carrier Grade Edition”](#).

RPMs are also available for both 32-bit and 64-bit Linux platforms. For a MySQL Cluster, three RPMs are required:

- The **Server** RPM (for example, `MySQL-server-5.1.21-beta-0.glibc23.i386.rpm`), which supplies the core files needed to run a MySQL Server and a MySQL Server binary with clustering support.
- The **NDB Cluster - Storage engine** RPM (for example, `MySQL-ndb-storage-5.1.21-beta-0.glibc23.i386.rpm`), which supplies the MySQL Cluster data node binary (`ndbd`).
- The **NDB Cluster - Storage engine management RPM** (for example, `MySQL-ndb-management-5.1.21-beta-0.glibc23.i386.rpm`), which provides the MySQL Cluster management server binary (`ndb_mgmd`).

In addition, you should also obtain the **NDB Cluster - Storage engine basic tools** RPM (for example, `MySQL-ndb-tools-5.1.21-beta-0.glibc23.i386.rpm`), which supplies several useful applications for working with a MySQL Cluster. The most important of these is the MySQL Cluster management client (`ndb_mgm`). The **NDB Cluster - Storage engine extra tools** RPM (for example, `MySQL-ndb-extra-5.1.21-beta-0.glibc23.i386.rpm`) contains some additional testing and monitoring programs, but is not required to install a MySQL Cluster. (For more information about these additional programs, see [Section 16.9, “Cluster Utility Programs”](#).)

The MySQL version number in the RPM filenames (shown here as `5.1.21-beta`) can vary according to the version which you are actually using. *It is very important that all of the Cluster RPMs to be installed have the same MySQL version number.* The `glibc` version number (if present — shown here as `glibc23`), and architecture designation (shown here as `i386`) should be appropriate to the machine on which the RPM is to be installed.

See [Section 2.4, “Installing MySQL from RPM Packages on Linux”](#), for general information about installing MySQL using RPMs supplied by MySQL AB.

After installing from RPM, you still need to configure the cluster as discussed in [Section 16.3.3, “Multi-Computer Configuration”](#).

The following information applies to all MySQL Cluster users.

Note

After completing the installation, do not yet start any of the binaries. We show you how to do so following the configuration of all nodes.

Data and SQL Node Installation — `.tar.gz` Binary

On each of the machines designated to host data or SQL nodes, perform the following steps as the system `root` user:

1. Check your `/etc/passwd` and `/etc/group` files (or use whatever tools are provided by your operating system for managing users and groups) to see whether there is already a `mysql` group and `mysql` user on the system. Some OS distributions create

these as part of the operating system installation process. If they are not already present, create a new `mysql` user group, and then add a `mysql` user to this group:

```
shell> groupadd mysql
shell> useradd -g mysql mysql
```

The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix, or they may have different names such as `adduser` and `addgroup`.

2. Change location to the directory containing the downloaded file, unpack the archive, and create a symlink to the `mysql` directory. Note that the actual file and directory names will vary according to the MySQL version number.

```
shell> cd /var/tmp
shell> tar -C /usr/local -xzf mysql-5.1.21-beta-pc-linux-gnu-i686.tar.gz
shell> ln -s /usr/local/mysql-5.1.21-beta-pc-linux-gnu-i686 /usr/local/mysql
```

3. Change location to the `mysql` directory and run the supplied script for creating the system databases:

```
shell> cd mysql
shell> scripts/mysql_install_db --user=mysql
```

4. Set the necessary permissions for the MySQL server and data directories:

```
shell> chown -R root .
shell> chown -R mysql data
shell> chgrp -R mysql .
```

Note that the data directory on each machine hosting a data node is `/usr/local/mysql/data`. We will use this piece of information when we configure the management node. (See [Section 16.3.3, “Multi-Computer Configuration”](#).)

5. Copy the MySQL startup script to the appropriate directory, make it executable, and set it to start when the operating system is booted up:

```
shell> cp support-files/mysql.server /etc/rc.d/init.d/
shell> chmod +x /etc/rc.d/init.d/mysql.server
shell> chkconfig --add mysql.server
```

(The startup scripts directory may vary depending on your operating system and version — for example, in some Linux distributions, it is `/etc/init.d`.)

Here we use Red Hat's `chkconfig` for creating links to the startup scripts; use whatever means is appropriate for this purpose on your operating system and distribution, such as `update-rc.d` on Debian.

Remember that the preceding steps must be performed separately on each machine where a data node or SQL node is to reside.

MySQL Cluster 5.1 Carrier Grade Edition

The following information does not apply to users of MySQL Cluster 5.1 Carrier Grade Edition. For more information about MySQL Cluster 5.1 Carrier Grade Edition, see [Section 16.2, “MySQL Cluster 5.1 Carrier Grade Edition”](#).

SQL node installation — RPM files. On each machine to be used for hosting a cluster SQL node, install the MySQL RPM by executing the following command as the system root user, replacing the name shown for the RPM as necessary to match the name of the RPM downloaded from the MySQL AB web site:

```
shell> rpm -Uhv MySQL-server-5.1.21-beta-0.glibc23.i386.rpm
```

This installs the MySQL server binary (`mysqld`) in the `/usr/sbin` directory, as well as all needed MySQL Server support files. It also installs the `mysql.server` and `mysqld_safe` startup scripts in `/usr/share/mysql` and `/usr/bin`, respectively. The RPM installer should take care of general configuration issues (such as creating the `mysql` user and group, if needed) automatically.

MySQL Cluster 5.1 Carrier Grade Edition

The following information does not apply to users of MySQL Cluster 5.1 Carrier Grade Edition. For more information about MySQL Cluster 5.1 Carrier Grade Edition, see [Section 16.2, “MySQL Cluster 5.1 Carrier Grade Edition”](#).

Data Node Installation — RPM Files

On a computer that is to host a cluster data node it is necessary to install only the **NDB Cluster - Storage engine** RPM. To do so, copy this RPM to the data node host, and run the following command as the system root user, replacing the name shown for the RPM as necessary to match that of the RPM downloaded from the MySQL AB web site:

```
shell> rpm -Uvh MySQL-ndb-storage-5.1.21-beta-0.glibc23.i386.rpm
```

The previous command installs the MySQL Cluster data node binary (`ndbd`) in the `/usr/sbin` directory.

The following information applies to all MySQL Cluster users.

Management Node Installation — .tar.gz Binary

Installation for the management (MGM) node does not require installation of the `mysqld` binary. Only the binaries for the MGM server and client are required, which can be found in the downloaded archive. Again, we assume that you have placed this file in `/var/tmp`.

As system `root` (that is, after using `sudo`, `su root`, or your system's equivalent for temporarily assuming the system administrator account's privileges), perform the following steps to install `ndb_mgmd` and `ndb_mgm` on the Cluster management node host:

1. Change location to the `/var/tmp` directory, and extract the `ndb_mgm` and `ndb_mgmd` from the archive into a suitable directory such as `/usr/local/bin`:

```
shell> cd /var/tmp
shell> tar -zxvf mysql-5.1.21-beta-pc-linux-gnu-i686.tar.gz
shell> cd mysql-5.1.21-beta-pc-linux-gnu-i686
shell> cp /bin/ndb_mgm* /usr/local/bin
```

(You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from `/var/tmp` once `ndb_mgm` and `ndb_mgmd` have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

```
shell> cd /usr/local/bin
shell> chmod +x ndb_mgm*
```

MySQL Cluster 5.1 Carrier Grade Edition

The following information does not apply to users of MySQL Cluster 5.1 Carrier Grade Edition. For more information about MySQL Cluster 5.1 Carrier Grade Edition, see Section 16.2, "MySQL Cluster 5.1 Carrier Grade Edition".

Management Node Installation — RPM File

To install the MySQL Cluster management server, it is necessary only to use the **NDB Cluster - Storage engine management** RPM. Copy this RPM to the computer intended to host the management node, and then install it by running the following command as the system root user (replace the name shown for the RPM as necessary to match that of the **Storage engine management** RPM downloaded from the MySQL AB web site):

```
shell> rpm -Uvh MySQL-ndb-management-5.1.21-beta-0.glibc23.i386.rpm
```

This installs the management server binary (`ndb_mgmd`) to the `/usr/sbin` directory.

You should also install the **NDB** management client, which is supplied by the **Storage engine basic tools** RPM. Copy this RPM to the same computer as the management node, and then install it by running the following command as the system root user (again, replace the name shown for the RPM as necessary to match that of the **Storage engine basic tools** RPM downloaded from the MySQL AB web site):

```
shell> rpm -Uvh MySQL-ndb-tools-5.1.21-beta-0.glibc23.i386.rpm
```

The **Storage engine basic tools** RPM installs the MySQL Cluster management client (`ndb_mgm`) to the `/usr/bin` directory.

In Section 16.3.3, "Multi-Computer Configuration", we create configuration files for all of the nodes in our example Cluster.

16.3.3. Multi-Computer Configuration

For our four-node, four-host MySQL Cluster, it is necessary to write four configuration files, one per node host.

- Each data node or SQL node requires a `my.cnf` file that provides two pieces of information: a *connectstring* that tells the node where to find the MGM node, and a line telling the MySQL server on this host (the machine hosting the data node) to run in NDB mode.

For more information on connectstrings, see [Section 16.4.4.2, “The Cluster Connectstring”](#).

- The management node needs a `config.ini` file telling it how many replicas to maintain, how much memory to allocate for data and indexes on each data node, where to find the data nodes, where to save data to disk on each data node, and where to find any SQL nodes.

Configuring the Storage and SQL Nodes

The `my.cnf` file needed for the data nodes is fairly simple. The configuration file should be located in the `/etc` directory and can be edited using any text editor. (Create the file if it does not exist.) For example:

```
shell> vi /etc/my.cnf
```

We show `vi` being used here to create the file, but any text editor should work just as well.

For each data node and SQL node in our example setup, `my.cnf` should look like this:

```
# Options for mysqld process:
[MYSQLD]
ndbcluster                # run NDB storage engine
ndb-connectstring=192.168.0.10 # location of management server

# Options for ndbd process:
[MYSQL_CLUSTER]
ndb-connectstring=192.168.0.10 # location of management server
```

After entering the preceding information, save this file and exit the text editor. Do this for the machines hosting data node “A”, data node “B”, and the SQL node.

Important

Once you have started a `mysqld` process with the `ndbcluster` and `ndb-connectstring` parameters in the `[MYSQLD]` in the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements will fail with an error. *This is by design.*

Configuring the management node. The first step in configuring the MGM node is to create the directory in which the configuration file can be found and then to create the file itself. For example (running as `root`):

```
shell> mkdir /var/lib/mysql-cluster
shell> cd /var/lib/mysql-cluster
shell> vi config.ini
```

For our representative setup, the `config.ini` file should read as follows:

```
# Options affecting ndbd processes on all data nodes:
[NDBD DEFAULT]
NoOfReplicas=2      # Number of replicas
DataMemory=80M      # How much memory to allocate for data storage
IndexMemory=18M     # How much memory to allocate for index storage
                    # For DataMemory and IndexMemory, we have used the
                    # default values. Since the "world" database takes up
                    # only about 500KB, this should be more than enough for
                    # this example cluster setup.

# TCP/IP options:
[TCP DEFAULT]
portnumber=2202     # This the default; however, you can use any
                    # port that is free for all the hosts in the cluster
                    # Note: It is recommended that you do not specify the
                    # portnumber at all and allow the default value to be
                    # used instead

# Management process options:
```

```
[NDB_MGMD]
hostname=192.168.0.10      # Hostname or IP address of MGM node
datadir=/var/lib/mysql-cluster # Directory for MGM node log files

# Options for data node "A":
[NDBD]
# (one [NDBD] section per data node)
hostname=192.168.0.30      # Hostname or IP address
datadir=/usr/local/mysql/data # Directory for this data node's data files

# Options for data node "B":
[NDBD]
hostname=192.168.0.40      # Hostname or IP address
datadir=/usr/local/mysql/data # Directory for this data node's data files

# SQL node options:
[MYSQLD]
hostname=192.168.0.20      # Hostname or IP address
# (additional mysqld connections can be
# specified for this node for various
# purposes such as running ndb_restore)
```

Note

The `world` database can be downloaded from <http://dev.mysql.com/doc/>, where it can be found listed under “Examples”.

After all the configuration files have been created and these minimal options have been specified, you are ready to proceed with starting the cluster and verifying that all processes are running. We discuss how this is done in [Section 16.3.4, “Initial Startup”](#).

For more detailed information about the available MySQL Cluster configuration parameters and their uses, see [Section 16.4.4, “Configuration File”](#), and [Section 16.4, “MySQL Cluster Configuration”](#). For configuration of MySQL Cluster as relates to making backups, see [Section 16.8.4, “Configuration for Cluster Backup”](#).

Note

The default port for Cluster management nodes is 1186; the default port for data nodes is 2202. However, the cluster can automatically allocate ports for data nodes from those that are already free.

16.3.4. Initial Startup

Starting the cluster is not very difficult after it has been configured. Each cluster node process must be started separately, and on the host where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes:

1. On the management host, issue the following command from the system shell to start the management node process:

```
shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
```

Note that `ndb_mgmd` must be told where to find its configuration file, using the `-f` or `--config-file` option. (See [Section 16.6.3, “ndb_mgmd — The Management Server Process”](#), for details.)

2. On each of the data node hosts, run this command to start the `ndbd` process:

```
shell> ndbd
```

- 3.

MySQL Cluster 5.1 Carrier Grade Edition

The following information does not apply to users of MySQL Cluster 5.1 Carrier Grade Edition. For more information about MySQL Cluster 5.1 Carrier Grade Edition, see [Section 16.2, “MySQL Cluster 5.1 Carrier Grade Edition”](#).

If you used RPM files to install MySQL on the cluster host where the SQL node is to reside, you can (and should) use the supplied startup script to start the MySQL server process on the SQL node.

The following information applies to all MySQL Cluster users.

If all has gone well, and the cluster has been set up correctly, the cluster should now be operational. You can test this by invoking the `ndb_mgm` management node client. The output should look like that shown here, although you might see some slight differences in the

output depending upon the exact version of MySQL that you are using:

```
shell> ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=2 @192.168.0.30 (Version: 5.1.21-beta, Nodegroup: 0, Master)
id=3 @192.168.0.40 (Version: 5.1.21-beta, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=1 @192.168.0.10 (Version: 5.1.21-beta)

[mysqld(SQL)] 1 node(s)
id=4 (Version: 5.1.21-beta)
```

Note

The SQL node is referenced here as `[mysqld(API)]`. This is perfectly normal, and reflects the fact that the `mysqld` process is acting as a cluster API node.

You should now be ready to work with databases, tables, and data in MySQL Cluster. See [Section 16.3.5, “Loading Sample Data and Performing Queries”](#), for a brief discussion.

16.3.5. Loading Sample Data and Performing Queries

Working with data in MySQL Cluster is not much different from doing so in MySQL without Cluster. There are two points to keep in mind:

- For a table to be replicated in the cluster, it must use the **NDB Cluster** storage engine. To specify this, use the **ENGINE=NDB** or **ENGINE=NDBCLUSTER** table option. You can add this option when creating the table:

```
CREATE TABLE tbl_name (column_definitions) ENGINE=NDBCLUSTER;
```

Alternatively, for an existing table that uses a different storage engine, use **ALTER TABLE** to change the table to use **NDB Cluster**:

```
ALTER TABLE tbl_name ENGINE=NDBCLUSTER;
```

- Each **NDB** table *must* have a primary key. If no primary key is defined by the user when a table is created, the **NDB Cluster** storage engine automatically generates a hidden one.

Note

This hidden key takes up space just as does any other table index. It is not uncommon to encounter problems due to insufficient memory for accommodating these automatically created indexes.)

If you are importing tables from an existing database using the output of `mysqldump`, you can open the SQL script in a text editor and add the **ENGINE** option to any table creation statements, or replace any existing **ENGINE** (or **TYPE**) options. Suppose that you have the **world** sample database on another MySQL server that does not support MySQL Cluster, and you want to export the **City** table:

```
shell> mysqldump --add-drop-table world City > city_table.sql
```

The resulting `city_table.sql` file will contain this table creation statement (and the **INSERT** statements necessary to import the table data):

```
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
  `CountryCode` char(3) NOT NULL default '',
  `District` char(20) NOT NULL default '',
  `Population` int(11) NOT NULL default '0',
  PRIMARY KEY (`ID`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabul',1780000);
```

```
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
(remaining INSERT statements omitted)
```

You need to make sure that MySQL uses the **NDB** storage engine for this table. There are two ways that this can be accomplished. One of these is to modify the table definition *before* importing it into the Cluster database. Using the **City** table as an example, modify the **ENGINE** option of the definition as follows:

```
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
  `CountryCode` char(3) NOT NULL default '',
  `District` char(20) NOT NULL default '',
  `Population` int(11) NOT NULL default '0',
  PRIMARY KEY (`ID`)
) ENGINE=NDBCLUSTER DEFAULT CHARSET=latin1;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabul',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
(remaining INSERT statements omitted)
```

This must be done for the definition of each table that is to be part of the clustered database. The easiest way to accomplish this is to do a search-and-replace on the file that contains the definitions and replace all instances of **TYPE=engine_name** or **ENGINE=en-gine_name** with **ENGINE=NDBCLUSTER**. If you do not want to modify the file, you can use the unmodified file to create the tables, and then use **ALTER TABLE** to change their storage engine. The particulars are given later in this section.

Assuming that you have already created a database named **world** on the SQL node of the cluster, you can then use the **mysql** command-line client to read **city_table.sql**, and create and populate the corresponding table in the usual manner:

```
shell> mysql world < city_table.sql
```

It is very important to keep in mind that the preceding command must be executed on the host where the SQL node is running (in this case, on the machine with the IP address **192.168.0.20**).

To create a copy of the entire **world** database on the SQL node, use **mysqldump** on the non-cluster server to export the database to a file named **world.sql**; for example, in the **/tmp** directory. Then modify the table definitions as just described and import the file into the SQL node of the cluster like this:

```
shell> mysql world < /tmp/world.sql
```

If you save the file to a different location, adjust the preceding instructions accordingly.

It is important to note that **NDB Cluster** in MySQL 5.1 does not support autodiscovery of databases. (See [Section 16.13, “Known Limitations of MySQL Cluster”](#).) This means that, once the **world** database and its tables have been created on one data node, you need to issue the **CREATE DATABASE world** statement (or you may use **CREATE SCHEMA world** instead), followed by **FLUSH TABLES** on each SQL node in the cluster. This causes the node to recognize the database and read its table definitions.

Running **SELECT** queries on the SQL node is no different from running them on any other instance of a MySQL server. To run queries from the command line, you first need to log in to the MySQL Monitor in the usual way (specify the **root** password at the **Enter password:** prompt):

```
shell> mysql -u root -p
Enter password:
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 5.1.21-beta

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

We simply use the MySQL server's **root** account and assume that you have followed the standard security precautions for installing a MySQL server, including setting a strong **root** password. For more information, see [Section 2.10.3, “Securing the Initial MySQL Accounts”](#).

It is worth taking into account that Cluster nodes do *not* make use of the MySQL privilege system when accessing one another. Setting or changing MySQL user accounts (including the **root** account) effects only applications that access the SQL node, not interaction between nodes.

If you did not modify the **ENGINE** clauses in the table definitions prior to importing the SQL script, you should run the following statements at this point:

```
mysql> USE world;
mysql> ALTER TABLE City ENGINE=NDBCLUSTER;
mysql> ALTER TABLE Country ENGINE=NDBCLUSTER;
mysql> ALTER TABLE CountryLanguage ENGINE=NDBCLUSTER;
```

Selecting a database and running a **SELECT** query against a table in that database is also accomplished in the usual manner, as is exiting the MySQL Monitor:

```
mysql> USE world;
mysql> SELECT Name, Population FROM City ORDER BY Population DESC LIMIT 5;
+-----+-----+
| Name      | Population |
+-----+-----+
| Bombay    | 10500000  |
| Seoul     | 9981619   |
| São Paulo | 9968485   |
| Shanghai  | 9696300   |
| Jakarta   | 9604900   |
+-----+-----+
5 rows in set (0.34 sec)

mysql> \q
Bye

shell>
```

Applications that use MySQL can employ standard APIs to access **NDB** tables. It is important to remember that your application must access the SQL node, and not the management or data nodes. This brief example shows how we might execute the **SELECT** statement just shown by using the PHP 5.X **mysqli** extension running on a Web server elsewhere on the network:

```
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN"
"http://www.w3.org/TR/html4/loose.dtd">
<html>
<head>
  <meta http-equiv="Content-Type"
        content="text/html; charset=iso-8859-1">
  <title>SIMPLE mysqli SELECT</title>
</head>
<body>
<?php
  # connect to SQL node:
  $link = new mysqli('192.168.0.20', 'root', 'root_password', 'world');
  # parameters for mysqli constructor are:
  #   host, user, password, database

  if( mysqli_connect_errno() )
    die("Connect failed: " . mysqli_connect_error());

  $query = "SELECT Name, Population
            FROM City
            ORDER BY Population DESC
            LIMIT 5";

  # if no errors...
  if( $result = $link->query($query) )
  {
    ?>
    <table border="1" width="40%" cellpadding="4" cellspacing="1">
    <tbody>
    <tr>
      <th width="10%">City</th>
      <th>Population</th>
    </tr>
    <?
      # then display the results...
      while($row = $result->fetch_object())
        printf(<tr>\n  <td align="center">%s</td><td>%d</td>\n</tr>\n",
              $row->Name, $row->Population);
    ?>
    </tbody>
    </table>
    <?
      # ...and verify the number of rows that were retrieved
      printf("<p>Affected rows: %d</p>\n", $link->affected_rows);
    }
    else
      # otherwise, tell us what went wrong
      echo mysqli_error();

    # free the result set and the mysqli connection object
```

```
$result->close();  
$link->close();  
?>  
</body>  
</html>
```

We assume that the process running on the Web server can reach the IP address of the SQL node.

In a similar fashion, you can use the MySQL C API, Perl-DBI, Python-mysql, or MySQL AB's own Connectors to perform the tasks of data definition and manipulation just as you would normally with MySQL.

16.3.6. Safe Shutdown and Restart

To shut down the cluster, enter the following command in a shell on the machine hosting the management node:

```
shell> ndb_mgm -e shutdown
```

The `-e` option here is used to pass a command to the `ndb_mgm` client from the shell. See [Section 4.3.1, “Using Options on the Command Line”](#). The command causes the `ndb_mgm`, `ndb_mgmd`, and any `ndbd` processes to terminate gracefully. Any SQL nodes can be terminated using `mysqldadmin shutdown` and other means.

To restart the cluster, run these commands:

- On the management host (`192.168.0.10` in our example setup):

```
shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
```

- On each of the data node hosts (`192.168.0.30` and `192.168.0.40`):

```
shell> ndbd
```

- On the SQL host (`192.168.0.20`):

```
shell> mysqld_safe &
```

For information on making Cluster backups, see [Section 16.8.2, “Using The Management Client to Create a Backup”](#).

To restore the cluster from backup requires the use of the `ndb_restore` command. This is covered in [Section 16.8.3, “ndb_restore — Restore a Cluster Backup”](#).

More information on configuring MySQL Cluster can be found in [Section 16.4, “MySQL Cluster Configuration”](#).

16.4. MySQL Cluster Configuration

A MySQL server that is part of a MySQL Cluster differs in only one respect from a normal (non-clustered) MySQL server, in that it employs the **NDB Cluster** storage engine. This engine is also referred to simply as **NDB**, and the two forms of the name are synonymous.

To avoid unnecessary allocation of resources, the server is configured by default with the **NDB** storage engine disabled. To enable **NDB**, you must modify the server's `my.cnf` configuration file, or start the server with the `--ndbcluster` option.

The MySQL server is a part of the cluster, so it also must know how to access an MGM node to obtain the cluster configuration data. The default behavior is to look for the MGM node on `localhost`. However, should you need to specify that its location is elsewhere, this can be done in `my.cnf` or on the MySQL server command line. Before the **NDB** storage engine can be used, at least one MGM node must be operational, as well as any desired data nodes.

16.4.1. Building MySQL Cluster from Source Code

NDB, the Cluster storage engine, is available in binary distributions for Linux, Mac OS X, and Solaris. We are working to make Cluster run on all operating systems supported by MySQL, including Windows.

If you choose to build from a source tarball or the MySQL 5.1 BitKeeper tree, be sure to use the `--with-ndbcluster` option when

running `configure`. You can also use the `BUILD/compile-pentium-max` build script. Note that this script includes OpenSSL, so you must either have or obtain OpenSSL to build successfully, or else modify `compile-pentium-max` to exclude this requirement. Of course, you can also just follow the standard instructions for compiling your own binaries, and then perform the usual tests and installation procedure. See [Section 2.9.3, “Installing from the Development Source Tree”](#).

MySQL Cluster 5.1 Carrier Grade Edition

The following information applies to users of MySQL Cluster 5.1 Carrier Grade Edition only. For more information about MySQL Cluster 5.1 Carrier Grade Edition, see [Section 16.2, “MySQL Cluster 5.1 Carrier Grade Edition”](#).

Warning

`BUILD/compile-pentium-max` by default builds the MySQL Server with support for the `InnoDB` storage engine. *You must not deploy or make use of MySQL MySQL Cluster 5.1 Carrier Grade Edition employing the `InnoDB` storage engine without prior written permission to do so from MySQL AB.*

If you wish to use `InnoDB` technology in conjunction with your use of MySQL MySQL Cluster 5.1 Carrier Grade Edition and do not already have authorization to do so as part of your MySQL Server license, contact your MySQL AB salesperson or other authorized MySQL AB representative for assistance in upgrading your MySQL Server license.

The following information applies to all MySQL Cluster users.

`BUILD/compile-pentium-max` also includes OpenSSL, so you must either have or obtain OpenSSL to build successfully, or else modify `compile-pentium-max` to exclude this requirement. Of course, you can also just follow the standard instructions for compiling your own binaries, and then perform the usual tests and installation procedure. See [Section 2.9.3, “Installing from the Development Source Tree”](#).

You should also note that `compile-pentium-max` installs MySQL to the directory `/usr/local/mysql`, placing all MySQL Cluster executables, scripts, databases, and support files in subdirectories under this directory. If this is not what you desire, be sure to modify the script accordingly.

16.4.2. Installing the Cluster Software

In the next few sections, we assume that you are already familiar with installing MySQL, and here we cover only the differences between configuring MySQL Cluster and configuring MySQL without clustering. (See [Chapter 2, *Installing and Upgrading MySQL*](#), if you require more information about the latter.)

You will find Cluster configuration easiest if you have already have all management and data nodes running first; this is likely to be the most time-consuming part of the configuration. Editing the `my.cnf` file is fairly straightforward, and this section will cover only any differences from configuring MySQL without clustering.

16.4.3. Quick Test Setup of MySQL Cluster

To familiarize you with the basics, we will describe the simplest possible configuration for a functional MySQL Cluster. After this, you should be able to design your desired setup from the information provided in the other relevant sections of this chapter.

First, you need to create a configuration directory such as `/var/lib/mysql-cluster`, by executing the following command as the system `root` user:

```
shell> mkdir /var/lib/mysql-cluster
```

In this directory, create a file named `config.ini` that contains the following information. Substitute appropriate values for `Host-Name` and `DataDir` as necessary for your system.

```
# file "config.ini" - showing minimal setup consisting of 1 data node,
# 1 management server, and 3 MySQL servers.
# The empty default sections are not required, and are shown only for
# the sake of completeness.
# Data nodes must provide a hostname but MySQL Servers are not required
# to do so.
# If you don't know the hostname for your machine, use localhost.
# The DataDir parameter also has a default value, but it is recommended to
# set it explicitly.
# Note: DB, API, and MGM are aliases for NDBD, MYSQLD, and NDB_MGMD
# respectively. DB and API are deprecated and should not be used in new
# installations.
[NDBD DEFAULT]
NoOfReplicas= 1
```

```
[MYSQLD DEFAULT]
[NDB_MGMD DEFAULT]
[TCP DEFAULT]

[NDB_MGMD]
HostName= myhost.example.com

[NDBD]
HostName= myhost.example.com
DataDir= /var/lib/mysql-cluster

[MYSQLD]
[MYSQLD]
[MYSQLD]
```

You can now start the `ndb_mgmd` management server. By default, it attempts to read the `config.ini` file in its current working directory, so change location into the directory where the file is located and then invoke `ndb_mgmd`:

```
shell> cd /var/lib/mysql-cluster
shell> ndb_mgmd
```

Then start a single data node by running `ndbd`:

```
shell> ndbd
```

By default, `ndbd` looks for the management server at `localhost` on port 1186.

Note

If you have installed MySQL from a binary tarball, you will need to specify the path of the `ndb_mgmd` and `ndbd` servers explicitly. (Normally, these will be found in `/usr/local/mysql/bin`.)

Finally, change location to the MySQL data directory (usually `/var/lib/mysql` or `/usr/local/mysql/data`), and make sure that the `my.cnf` file contains the option necessary to enable the NDB storage engine:

```
[mysqld]
ndbcluster
```

You can now start the MySQL server as usual:

```
shell> mysqld_safe --user=mysql &
```

Wait a moment to make sure the MySQL server is running properly. If you see the notice `mysql ended`, check the server's `.err` file to find out what went wrong.

If all has gone well so far, you now can start using the cluster. Connect to the server and verify that the `NDBCLUSTER` storage engine is enabled:

```
shell> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 5.1.21-beta

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SHOW ENGINES\G
...
***** 12. row *****
Engine: NDBCLUSTER
Support: YES
Comment: Clustered, fault-tolerant, memory-based tables
***** 13. row *****
Engine: NDB
Support: YES
Comment: Alias for NDBCLUSTER
...
```

The row numbers shown in the preceding example output may be different from those shown on your system, depending upon how your server is configured.

Try to create an `NDBCLUSTER` table:

```
shell> mysql
```

```
mysql> USE test;
Database changed

mysql> CREATE TABLE ctest (i INT) ENGINE=NDBCLUSTER;
Query OK, 0 rows affected (0.09 sec)

mysql> SHOW CREATE TABLE ctest \G
***** 1. row *****
      Table: ctest
Create Table: CREATE TABLE `ctest` (
  `i` int(11) default NULL
) ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

To check that your nodes were set up properly, start the management client:

```
shell> ndb_mgm
```

Use the **SHOW** command from within the management client to obtain a report on the cluster's status:

```
ndb_mgm> SHOW
Cluster Configuration
-----
[ndbd(NDB)] 1 node(s)
id=2 @127.0.0.1 (Version: 3.5.3, Nodegroup: 0, Master)

[ndb_mgmd(MGM)] 1 node(s)
id=1 @127.0.0.1 (Version: 3.5.3)

[mysqld(API)] 3 node(s)
id=3 @127.0.0.1 (Version: 3.5.3)
id=4 (not connected, accepting connect from any host)
id=5 (not connected, accepting connect from any host)
```

At this point, you have successfully set up a working MySQL Cluster. You can now store data in the cluster by using any table created with **ENGINE=NDBCLUSTER** or its alias **ENGINE=NDB**.

16.4.4. Configuration File

Configuring MySQL Cluster requires working with two files:

- **my.cnf**: Specifies options for all MySQL Cluster executables. This file, with which you should be familiar with from previous work with MySQL, must be accessible by each executable running in the cluster.
- **config.ini**: This file is read only by the MySQL Cluster management server, which then distributes the information contained therein to all processes participating in the cluster. **config.ini** contains a description of each node involved in the cluster. This includes configuration parameters for data nodes and configuration parameters for connections between all nodes in the cluster. For a quick reference to the sections that can appear in this file, and what sorts of configuration parameters may be placed in each section, see [Sections of the config.ini File](#).

We are continuously making improvements in Cluster configuration and attempting to simplify this process. Although we strive to maintain backward compatibility, there may be times when introduce an incompatible change. In such cases we will try to let Cluster users know in advance if a change is not backward compatible. If you find such a change and we have not documented it, please report it in the MySQL bugs database using the instructions given in [Section 1.8, “How to Report Bugs or Problems”](#).

16.4.4.1. Basic Example Configuration

To support MySQL Cluster, you will need to update **my.cnf** as shown in the following example. Note that the options shown here should not be confused with those that are used in **config.ini** files. You may also specify these parameters on the command line when invoking the executables.

```
# my.cnf
# example additions to my.cnf for MySQL Cluster
# (valid in MySQL 5.1)

# enable ndbcluster storage engine, and provide connectstring for
# management server host (default port is 1186)
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com
```

```
# provide connectstring for management server host (default port: 1186)
[ndbd]
connect-string=ndb_mgmd.mysql.com

# provide connectstring for management server host (default port: 1186)
[ndb_mgm]
connect-string=ndb_mgmd.mysql.com

# provide location of cluster configuration file
[ndb_mgmd]
config-file=/etc/config.ini
```

(For more information on connectstrings, see [Section 16.4.4.2, “The Cluster Connectstring”](#).)

```
# my.cnf
# example additions to my.cnf for MySQL Cluster
# (will work on all versions)

# enable ndbcluster storage engine, and provide connectstring for management
# server host to the default port 1186
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

Important

Once you have started a `mysqld` process with the `ndbcluster` and `ndb-connectstring` parameters in the `[MYSQLD]` in the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements will fail with an error. *This is by design.*

You may also use a separate `[mysql_cluster]` section in the cluster `my.cnf` file for settings to be read and used by all executables:

```
# cluster-specific settings
[mysql_cluster]
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

For additional `NDB` variables that can be set in the `my.cnf` file, see [Section 5.2.3, “System Variables”](#).

The configuration file is named `config.ini` by default. It is read by `ndb_mgmd` at startup and can be placed anywhere. Its location and name are specified by using `--config-file=path_name` on the `ndb_mgmd` command line. If the configuration file is not specified, `ndb_mgmd` by default tries to read a file named `config.ini` located in the current working directory.

Currently, the configuration file is in INI format, which consists of sections preceded by section headings (surrounded by square brackets), followed by the appropriate parameter names and values. One deviation from the standard INI format is that the parameter name and value can be separated by a colon (':') as well as the equals sign ('='). Another deviation is that sections are not uniquely identified by section name. Instead, unique sections (such as two different nodes of the same type) are identified by a unique ID specified as a parameter within the section.

Default values are defined for most parameters, and can also be specified in `config.ini`. To create a default value section, simply add the word `DEFAULT` to the section name. For example, an `[NDBD]` section contains parameters that apply to a particular data node, whereas an `[NDBD DEFAULT]` section contains parameters that apply to all data nodes. Suppose that all data nodes should use the same data memory size. To configure them all, create an `[NDBD DEFAULT]` section that contains a `DataMemory` line to specify the data memory size.

At a minimum, the configuration file must define the computers and nodes involved in the cluster and on which computers these nodes are located. An example of a simple configuration file for a cluster consisting of one management server, two data nodes and two MySQL servers is shown here:

```
# file "config.ini" - 2 data nodes and 2 SQL nodes
# This file is placed in the startup directory of ndb_mgmd (the
# management server)
# The first MySQL Server can be started from any host. The second
# can be started only on the host mysqld_5.mysql.com

[NDBD DEFAULT]
NoOfReplicas= 2
DataDir= /var/lib/mysql-cluster

[NDB_MGMD]
Hostname= ndb_mgmd.mysql.com
DataDir= /var/lib/mysql-cluster

[NDBD]
```

```

HostName= ndbd_2.mysql.com

[NDBD]
HostName= ndbd_3.mysql.com

[MYSQLD]
[MYSQLD]
HostName= mysqld_5.mysql.com

```

Each node has its own section in the `config.ini` file. For example, this cluster has two data nodes, so the preceding configuration file contains two `[NDBD]` sections defining these nodes.

Note

Do not place comments on the same line as a section heading in the `config.ini` file; this causes the management server not to start because it cannot parse the configuration file in such cases.

Sections of the `config.ini` File

There are six different sections that you can use in the `config.ini` configuration file, as described in the following list:

- `[COMPUTER]`: Defines cluster hosts. This is not required to configure a viable MySQL Cluster, but it may be used as a convenience when setting up a large cluster. See [Section 16.4.4.3, “Defining Cluster Computers”](#), for more information.
- `[NDBD]`: Defines a cluster data node (`ndbd` process). See [Section 16.4.4.5, “Defining Data Nodes”](#), for details.
- `[MYSQLD]`: Defines the cluster's MySQL server nodes (also called SQL or API nodes). For a discussion of SQL node configuration, see [Section 16.4.4.6, “Defining SQL and Other API Nodes”](#).
- `[MGM]` or `[NDB_MGMD]`: Defines a cluster management server (MGM) node. For information concerning the configuration of MGM nodes, see [Section 16.4.4.4, “Defining the Management Server”](#).
- `[TCP]`: Defines a TCP/IP connection between cluster nodes, with TCP/IP being the default connection protocol. Normally, `[TCP]` or `[TCP_DEFAULT]` sections are not required to set up a MySQL Cluster, as the cluster handles this automatically; however, it may be necessary in some situations to override the defaults provided by the cluster. See [Section 16.4.4.7, “Cluster TCP/IP Connections”](#), for information about available TCP/IP configuration parameters and how to use them. (You may also find [Section 16.4.4.8, “TCP/IP Connections Using Direct Connections”](#) to be of interest in some cases.)
- `[SHM]`: Defines shared-memory connections between nodes. In MySQL 5.1, it is enabled by default, but should still be considered experimental. For a discussion of SHM interconnects, see [Section 16.4.4.9, “Shared-Memory Connections”](#).
- `[SCI]`: Defines *Scalable Coherent Interface* connections between cluster data nodes. Such connections require software which, while freely available, is not part of the MySQL Cluster distribution, as well as specialised hardware. See [Section 16.4.4.10, “SCI Transport Connections”](#) for detailed information about SCI interconnects.

You can define `DEFAULT` values for each section. All Cluster parameter names are case-insensitive, which differs from parameters specified in `my.cnf` or `my.ini` files.

16.4.4.2. The Cluster Connectstring

With the exception of the MySQL Cluster management server (`ndb_mgmd`), each node that is part of a MySQL Cluster requires a *connectstring* that points to the management server's location. This connectstring is used in establishing a connection to the management server as well as in performing other tasks depending on the node's role in the cluster. The syntax for a connectstring is as follows:

```

<connectstring> :=
    [<nodeid-specification>,<host-specification>[,<host-specification>]
<nodeid-specification> := node_id
<host-specification> := host_name[:port_num]

```

`node_id` is an integer larger than 1 which identifies a node in `config.ini`. `host_name` is a string representing a valid Internet host name or IP address. `port_num` is an integer referring to a TCP/IP port number.

```

example 1 (long):    "nodeid=2,myhost1:1100,myhost2:1100,192.168.0.3:1200"
example 2 (short):   "myhost1"

```

All nodes will use `localhost:1186` as the default connectstring value if none is provided. If `port_num` is omitted from the connectstring, the default port is 1186. This port should always be available on the network because it has been assigned by IANA for this purpose (see <http://www.iana.org/assignments/port-numbers> for details).

By listing multiple `<host-specification>` values, it is possible to designate several redundant management servers. A cluster node will attempt to contact successive management servers on each host in the order specified, until a successful connection has been established.

There are a number of different ways to specify the connectstring:

- Each executable has its own command-line option which enables specifying the management server at startup. (See the documentation for the respective executable.)
- It is also possible to set the connectstring for all nodes in the cluster at once by placing it in a `[mysql_cluster]` section in the management server's `my.cnf` file.
- For backward compatibility, two other options are available, using the same syntax:
 1. Set the `NDB_CONNECTSTRING` environment variable to contain the connectstring.
 2. Write the connectstring for each executable into a text file named `Ndb.cfg` and place this file in the executable's startup directory.

However, these are now deprecated and should not be used for new installations.

The recommended method for specifying the connectstring is to set it on the command line or in the `my.cnf` file for each executable.

The maximum length of a connectstring is 1024 characters.

16.4.4.3. Defining Cluster Computers

The `[COMPUTER]` section has no real significance other than serving as a way to avoid the need of defining host names for each node in the system. All parameters mentioned here are required.

- `Id`

This is an integer value, used to refer to the host computer elsewhere in the configuration file. This is not the same as the node ID.

- `HostName`

This is the computer's hostname or IP address.

16.4.4.4. Defining the Management Server

The `[NDB_MGMD]` section is used to configure the behavior of the management server. `[MGM]` can be used as an alias; the two section names are equivalent. All parameters in the following list are optional and assume their default values if omitted.

Note

If neither the `ExecuteOnComputer` nor the `HostName` parameter is present, the default value `localhost` will be assumed for both.

- `Id`

Each node in the cluster has a unique identity, which is represented by an integer value in the range 1 to 63 inclusive. This ID is used by all internal cluster messages for addressing the node.

- `ExecuteOnComputer`

This refers to the `Id` set for one of the computers defined in a `[COMPUTER]` section of the `config.ini` file.

- **PortNumber**

This is the port number on which the management server listens for configuration requests and management commands.

- **HostName**

Specifying this parameter defines the hostname of the computer on which the management node is to reside. To specify a hostname other than `localhost`, either this parameter or `ExecuteOnComputer` is required.

- **LogDestination**

This parameter specifies where to send cluster logging information. There are three options in this regard — `CONSOLE`, `SYSLOG`, and `FILE` — with `FILE` being the default:

- `CONSOLE` outputs the log to `stdout`:

```
CONSOLE
```

- `SYSLOG` sends the log to a `syslog` facility, possible values being one of `auth`, `authpriv`, `cron`, `daemon`, `ftp`, `kern`, `lpr`, `mail`, `news`, `syslog`, `user`, `uucp`, `local0`, `local1`, `local2`, `local3`, `local4`, `local5`, `local6`, or `local7`.

Note

Not every facility is necessarily supported by every operating system.

```
SYSLOG:facility=syslog
```

- `FILE` pipes the cluster log output to a regular file on the same machine. The following values can be specified:

- `filename`: The name of the log file.
- `maxsize`: The maximum size (in bytes) to which the file can grow before logging rolls over to a new file. When this occurs, the old log file is renamed by appending `.N` to the filename, where `N` is the next number not yet used with this name.
- `maxfiles`: The maximum number of log files.

```
FILE:filename=cluster.log,maxsize=1000000,maxfiles=6
```

The default value for the `FILE` parameter is

`FILE:filename=ndb_node_id_cluster.log,maxsize=1000000,maxfiles=6`, where `node_id` is the ID of the node.

It is possible to specify multiple log destinations separated by semicolons as shown here:

```
CONSOLE;SYSLOG:facility=local0;FILE:filename=/var/log/mgmd
```

- **ArbitrationRank**

This parameter is used to define which nodes can act as arbitrators. Only management nodes and SQL nodes can be arbitrators. `ArbitrationRank` can take one of the following values:

- `0`: The node will never be used as an arbitrator.
- `1`: The node has high priority; that is, it will be preferred as an arbitrator over low-priority nodes.
- `2`: Indicates a low-priority node which be used as an arbitrator only if a node with a higher priority is not available for that purpose.

Normally, the management server should be configured as an arbitrator by setting its `ArbitrationRank` to 1 (the default value) and that of all SQL nodes to 0.

Beginning with MySQL 5.1.16 (*MySQL Cluster 5.1 Carrier Grade Edition*: MySQL 5.1.15-ndb-6.1.3), it is possible to disable arbitration completely by setting `ArbitrationRank` to 0 on all management and SQL nodes.

- **ArbitrationDelay**

An integer value which causes the management server's responses to arbitration requests to be delayed by that number of milliseconds. By default, this value is 0; it is normally not necessary to change it.

- **DataDir**

This specifies the directory where output files from the management server will be placed. These files include cluster log files, process output files, and the daemon's process ID (PID) file. (For log files, this location can be overridden by setting the `FILE` parameter for `LogDestination` as discussed previously in this section.)

The default value for this parameter is the directory in which `ndb_mgmd` is located.

16.4.4.5. Defining Data Nodes

The `[NDBD]` and `[NDBD DEFAULT]` sections are used to configure the behavior of the cluster's data nodes. There are many parameters which control buffer sizes, pool sizes, timeouts, and so forth. The only mandatory parameters are:

- Either `ExecuteOnComputer` or `HostName`, which must be defined in the local `[NDBD]` section.
- The parameter `NoOfReplicas`, which must be defined in the `[NDBD DEFAULT]` section, as it is common to all Cluster data nodes.

Most data node parameters are set in the `[NDBD DEFAULT]` section. Only those parameters explicitly stated as being able to set local values are allowed to be changed in the `[NDBD]` section. Where present, `HostName`, `Id` and `ExecuteOnComputer` *must* be defined in the local `[NDBD]` section, and not in any other section of `config.ini`. In other words, settings for these parameters are specific to one data node.

For those parameters affecting memory usage or buffer sizes, it is possible to use `K`, `M`, or `G` as a suffix to indicate units of 1024, 1024×1024, or 1024×1024×1024. (For example, `100K` means $100 \times 1024 = 102400$.) Parameter names and values are currently case-sensitive.

Identifying data nodes. The `Id` value (that is, the data node identifier) can be allocated on the command line when the node is started or in the configuration file.

- **Id**

This is the node ID used as the address of the node for all cluster internal messages. This is an integer in the range 1 to 63 inclusive. Each node in the cluster must have a unique identity.

- **ExecuteOnComputer**

This refers to the `Id` set for one of the computers defined in a `[COMPUTER]` section.

- **HostName**

Specifying this parameter defines the hostname of the computer on which the data node is to reside. To specify a hostname other than `localhost`, either this parameter or `ExecuteOnComputer` is required.

ServerPort (OBSOLETE)

Each node in the cluster uses a port to connect to other nodes. This port is used also for non-TCP transporters in the connection setup phase. The default port is allocated dynamically in such a way as to ensure that no two nodes on the same computer receive the same port number, so it should not normally be necessary to specify a value for this parameter.

MySQL Cluster 5.1 Carrier Grade Edition

The following information applies to users of MySQL Cluster 5.1 Carrier Grade Edition only. For more information about MySQL Cluster 5.1 Carrier Grade Edition, see Section 16.2, “MySQL Cluster 5.1 Carrier Grade Edition”.

TcpBind_INADDR_ANY

Setting this parameter to **TRUE** or **1** binds **IP_ADDR_ANY** so that connections can be made from anywhere (for autogenerated connections). The default is **FALSE** (0).

This parameter was added in MySQL 5.1.16-ndb-6.2.0.

The following information applies to all MySQL Cluster users.

NoOfReplicas

This global parameter can be set only in the **[NDBD DEFAULT]** section, and defines the number of replicas for each table stored in the cluster. This parameter also specifies the size of node groups. A node group is a set of nodes all storing the same information.

Node groups are formed implicitly. The first node group is formed by the set of data nodes with the lowest node IDs, the next node group by the set of the next lowest node identities, and so on. By way of example, assume that we have 4 data nodes and that **NoOfReplicas** is set to 2. The four data nodes have node IDs 2, 3, 4 and 5. Then the first node group is formed from nodes 2 and 3, and the second node group by nodes 4 and 5. It is important to configure the cluster in such a manner that nodes in the same node groups are not placed on the same computer because a single hardware failure would cause the entire cluster to crash.

If no node IDs are provided, the order of the data nodes will be the determining factor for the node group. Whether or not explicit assignments are made, they can be viewed in the output of the management client's **SHOW** statement.

There is no default value for **NoOfReplicas**; the maximum possible value is 4.

Important

The value for this parameter must divide evenly into the number of data nodes in the cluster. For example, if there are two data nodes, then **NoOfReplicas** must be equal to either 1 or 2, since 2/3 and 2/4 both yield fractional values; if there are four data nodes, then **NoOfReplicas** must be equal to 1, 2, or 4.

DataDir

This parameter specifies the directory where trace files, log files, pid files and error logs are placed.

FileSystemPath

This parameter specifies the directory where all files created for metadata, REDO logs, UNDO logs (for Disk Data tables) and data files are placed. The default is the directory specified by **DataDir**.

Note

This directory must exist before the **ndbd** process is initiated.

The recommended directory hierarchy for MySQL Cluster includes **/var/lib/mysql-cluster**, under which a directory for the node's filesystem is created. The name of this subdirectory contains the node ID. For example, if the node ID is 2, this subdirectory is named **ndb_2_fs**.

BackupDataDir

This parameter specifies the directory in which backups are placed. If omitted, the default backup location is the directory named **BACKUP** under the location specified by the **FilePath** parameter. (See above.)

Data Memory, Index Memory, and String Memory

DataMemory and **IndexMemory** are [NDBD] parameters specifying the size of memory segments used to store the actual records and their indexes. In setting values for these, it is important to understand how **DataMemory** and **IndexMemory** are used, as they usually need to be updated to reflect actual usage by the cluster:

- **DataMemory**

This parameter defines the amount of space (in bytes) available for storing database records. The entire amount specified by this value is allocated in memory, so it is extremely important that the machine has sufficient physical memory to accommodate it.

The memory allocated by **DataMemory** is used to store both the actual records and indexes. There is a 16-byte overhead on each record; an additional amount for each record is incurred because it is stored in a 32KB page with 128 byte page overhead (see below). There is also a small amount wasted per page due to the fact that each record is stored in only one page.

For variable-size table attributes in MySQL 5.1, the data is stored on separate datapages, allocated from **DataMemory**. Variable-length records use a fixed-size part with an extra overhead of 4 bytes to reference the variable-size part. The variable-size part has 2 bytes overhead plus 2 bytes per attribute.

The maximum record size is currently 8052 bytes.

The memory space defined by **DataMemory** is also used to store ordered indexes, which use about 10 bytes per record. Each table row is represented in the ordered index. A common error among users is to assume that all indexes are stored in the memory allocated by **IndexMemory**, but this is not the case: Only primary key and unique hash indexes use this memory; ordered indexes use the memory allocated by **DataMemory**. However, creating a primary key or unique hash index also creates an ordered index on the same keys, unless you specify **USING HASH** in the index creation statement. This can be verified by running **ndb_desc -d db_name table_name** in the management client.

The memory space allocated by **DataMemory** consists of 32KB pages, which are allocated to table fragments. Each table is normally partitioned into the same number of fragments as there are data nodes in the cluster. Thus, for each node, there are the same number of fragments as are set in **NoOfReplicas**.

Once a page has been allocated, it is currently not possible to return it to the pool of free pages, except by deleting the table. (This also means that **DataMemory** pages, once allocated to a given table, cannot be used by other tables.) Performing a node recovery also compresses the partition because all records are inserted into empty partitions from other live nodes.

The **DataMemory** memory space also contains UNDO information: For each update, a copy of the unaltered record is allocated in the **DataMemory**. There is also a reference to each copy in the ordered table indexes. Unique hash indexes are updated only when the unique index columns are updated, in which case a new entry in the index table is inserted and the old entry is deleted upon commit. For this reason, it is also necessary to allocate enough memory to handle the largest transactions performed by applications using the cluster. In any case, performing a few large transactions holds no advantage over using many smaller ones, for the following reasons:

- Large transactions are not any faster than smaller ones
- Large transactions increase the number of operations that are lost and must be repeated in event of transaction failure
- Large transactions use more memory

The default value for **DataMemory** is 80MB; the minimum is 1MB. There is no maximum size, but in reality the maximum size has to be adapted so that the process does not start swapping when the limit is reached. This limit is determined by the amount of physical RAM available on the machine and by the amount of memory that the operating system may commit to any one process. 32-bit operating systems are generally limited to 2–4GB per process; 64-bit operating systems can use more. For large databases, it may be preferable to use a 64-bit operating system for this reason.

- **IndexMemory**

This parameter controls the amount of storage used for hash indexes in MySQL Cluster. Hash indexes are always used for primary

key indexes, unique indexes, and unique constraints. Note that when defining a primary key and a unique index, two indexes will be created, one of which is a hash index used for all tuple accesses as well as lock handling. It is also used to enforce unique constraints.

The size of the hash index is 25 bytes per record, plus the size of the primary key. For primary keys larger than 32 bytes another 8 bytes is added.

The default value for `IndexMemory` is 18MB. The minimum is 1MB.

- ### `StringMemory`

This parameter determines how much memory is allocated for strings such as table names, and is specified in an `[NDBD]` or `[NDBD DEFAULT]` section of the `config.ini` file. A value between 0 and 100 inclusive is interpreted as a percent of the maximum default value, which is calculated based on a number of factors including the number of tables, maximum table name size, maximum size of `.FRM` files, `MaxNoOfTriggers`, maximum column name size, and maximum default column value. In general it is safe to assume that the maximum default value is approximately 5 MB for a MySQL Cluster having 1000 tables.

A value greater than 100 is interpreted as a number of bytes.

The default value is 5 — that is, 5 percent of the default maximum, or roughly 5 KB. (Note that this is a change from previous versions of MySQL Cluster.)

Under most circumstances, the default value should be sufficient, but when you have a great many Cluster tables (1000 or more), it is possible to get Error 773 `OUT OF STRING MEMORY, PLEASE MODIFY STRINGMEMORY CONFIG PARAMETER: PERMANENT ERROR: SCHEMA ERROR`, in which case you should increase this value. 25 (25 percent) is not excessive, and should prevent this error from recurring in all but the most extreme conditions.

The following example illustrates how memory is used for a table. Consider this table definition:

```
CREATE TABLE example (  
  a INT NOT NULL,  
  b INT NOT NULL,  
  c INT NOT NULL,  
  PRIMARY KEY(a),  
  UNIQUE(b)  
) ENGINE=NDBCLUSTER;
```

For each record, there are 12 bytes of data plus 12 bytes overhead. Having no nullable columns saves 4 bytes of overhead. In addition, we have two ordered indexes on columns `a` and `b` consuming roughly 10 bytes each per record. There is a primary key hash index on the base table using roughly 29 bytes per record. The unique constraint is implemented by a separate table with `b` as primary key and `a` as a column. This other table consumes an additional 29 bytes of index memory per record in the `example` table as well 8 bytes of record data plus 12 bytes of overhead.

Thus, for one million records, we need 58MB for index memory to handle the hash indexes for the primary key and the unique constraint. We also need 64MB for the records of the base table and the unique index table, plus the two ordered index tables.

You can see that hash indexes takes up a fair amount of memory space; however, they provide very fast access to the data in return. They are also used in MySQL Cluster to handle uniqueness constraints.

Currently, the only partitioning algorithm is hashing and ordered indexes are local to each node. Thus, ordered indexes cannot be used to handle uniqueness constraints in the general case.

An important point for both `IndexMemory` and `DataMemory` is that the total database size is the sum of all data memory and all index memory for each node group. Each node group is used to store replicated information, so if there are four nodes with two replicas, there will be two node groups. Thus, the total data memory available is $2 \times \text{DataMemory}$ for each data node.

It is highly recommended that `DataMemory` and `IndexMemory` be set to the same values for all nodes. Data distribution is even over all nodes in the cluster, so the maximum amount of space available for any node can be no greater than that of the smallest node in the cluster.

`DataMemory` and `IndexMemory` can be changed, but decreasing either of these can be risky; doing so can easily lead to a node or even an entire MySQL Cluster that is unable to restart due to there being insufficient memory space. Increasing these values should be acceptable, but it is recommended that such upgrades are performed in the same manner as a software upgrade, beginning with an update of the configuration file, and then restarting the management server followed by restarting each data node in turn.

Updates do not increase the amount of index memory used. Inserts take effect immediately; however, rows are not actually deleted until the transaction is committed.

Transaction parameters. The next three [NDBD] parameters that we discuss are important because they affect the number of parallel transactions and the sizes of transactions that can be handled by the system. `MaxNoOfConcurrentTransactions` sets the number of parallel transactions possible in a node. `MaxNoOfConcurrentOperations` sets the number of records that can be in update phase or locked simultaneously.

Both of these parameters (especially `MaxNoOfConcurrentOperations`) are likely targets for users setting specific values and not using the default value. The default value is set for systems using small transactions, to ensure that these do not use excessive memory.

- `MaxNoOfConcurrentTransactions`

For each active transaction in the cluster there must be a record in one of the cluster nodes. The task of coordinating transactions is spread among the nodes. The total number of transaction records in the cluster is the number of transactions in any given node times the number of nodes in the cluster.

Transaction records are allocated to individual MySQL servers. Normally, there is at least one transaction record allocated per connection that using any table in the cluster. For this reason, one should ensure that there are more transaction records in the cluster than there are concurrent connections to all MySQL servers in the cluster.

This parameter must be set to the same value for all cluster nodes.

Changing this parameter is never safe and doing so can cause a cluster to crash. When a node crashes, one of the nodes (actually the oldest surviving node) will build up the transaction state of all transactions ongoing in the crashed node at the time of the crash. It is thus important that this node has as many transaction records as the failed node.

The default value is 4096.

- `MaxNoOfConcurrentOperations`

It is a good idea to adjust the value of this parameter according to the size and number of transactions. When performing transactions of only a few operations each and not involving a great many records, there is no need to set this parameter very high. When performing large transactions involving many records need to set this parameter higher.

Records are kept for each transaction updating cluster data, both in the transaction coordinator and in the nodes where the actual updates are performed. These records contain state information needed to find UNDO records for rollback, lock queues, and other purposes.

This parameter should be set to the number of records to be updated simultaneously in transactions, divided by the number of cluster data nodes. For example, in a cluster which has four data nodes and which is expected to handle 1,000,000 concurrent updates using transactions, you should set this value to $1000000 / 4 = 250000$.

Read queries which set locks also cause operation records to be created. Some extra space is allocated within individual nodes to accommodate cases where the distribution is not perfect over the nodes.

When queries make use of the unique hash index, there are actually two operation records used per record in the transaction. The first record represents the read in the index table and the second handles the operation on the base table.

The default value is 32768.

This parameter actually handles two values that can be configured separately. The first of these specifies how many operation records are to be placed with the transaction coordinator. The second part specifies how many operation records are to be local to the database.

A very large transaction performed on an eight-node cluster requires as many operation records in the transaction coordinator as there are reads, updates, and deletes involved in the transaction. However, the operation records of the are spread over all eight nodes. Thus, if it is necessary to configure the system for one very large transaction, it is a good idea to configure the two parts separately. `MaxNoOfConcurrentOperations` will always be used to calculate the number of operation records in the transaction coordinator portion of the node.

It is also important to have an idea of the memory requirements for operation records. These consume about 1KB per record.

- **MaxNoOfLocalOperations**

By default, this parameter is calculated as $1.1 \times \text{MaxNoOfConcurrentOperations}$. This fits systems with many simultaneous transactions, none of them being very large. If there is a need to handle one very large transaction at a time and there are many nodes, it is a good idea to override the default value by explicitly specifying this parameter.

Transaction temporary storage. The next set of [NDBD] parameters is used to determine temporary storage when executing a statement that is part of a Cluster transaction. All records are released when the statement is completed and the cluster is waiting for the commit or rollback.

The default values for these parameters are adequate for most situations. However, users with a need to support transactions involving large numbers of rows or operations may need to increase these values to enable better parallelism in the system, whereas users whose applications require relatively small transactions can decrease the values to save memory.

- **MaxNoOfConcurrentIndexOperations**

For queries using a unique hash index, another temporary set of operation records is used during a query's execution phase. This parameter sets the size of that pool of records. Thus, this record is allocated only while executing a part of a query. As soon as this part has been executed, the record is released. The state needed to handle aborts and commits is handled by the normal operation records, where the pool size is set by the parameter **MaxNoOfConcurrentOperations**.

The default value of this parameter is 8192. Only in rare cases of extremely high parallelism using unique hash indexes should it be necessary to increase this value. Using a smaller value is possible and can save memory if the DBA is certain that a high degree of parallelism is not required for the cluster.

- **MaxNoOfFiredTriggers**

The default value of **MaxNoOfFiredTriggers** is 4000, which is sufficient for most situations. In some cases it can even be decreased if the DBA feels certain the need for parallelism in the cluster is not high.

A record is created when an operation is performed that affects a unique hash index. Inserting or deleting a record in a table with unique hash indexes or updating a column that is part of a unique hash index fires an insert or a delete in the index table. The resulting record is used to represent this index table operation while waiting for the original operation that fired it to complete. This operation is short-lived but can still require a large number of records in its pool for situations with many parallel write operations on a base table containing a set of unique hash indexes.

- **TransactionBufferMemory**

The memory affected by this parameter is used for tracking operations fired when updating index tables and reading unique indexes. This memory is used to store the key and column information for these operations. It is only very rarely that the value for this parameter needs to be altered from the default.

The default value for **TransactionBufferMemory** is 1MB.

Normal read and write operations use a similar buffer, whose usage is even more short-lived. The compile-time parameter **ZATTRINBUF_FILESIZE** (found in `ndb/src/kernel/blocks/Dbtc/Dbtc.hpp`) set to 4000×128 bytes (500KB). A similar buffer for key information, **ZDATABUF_FILESIZE** (also in `Dbtc.hpp`) contains $4000 \times 16 = 62.5$ KB of buffer space. **Dbtc** is the module that handles transaction coordination.

Scans and buffering. There are additional [NDBD] parameters in the **DbLqh** module (in `ndb/src/kernel/blocks/DbLqh/DbLqh.hpp`) that affect reads and updates. These include **ZATTRINBUF_FILESIZE**, set by default to 10000×128 bytes (1250KB) and **ZDATABUF_FILE_SIZE**, set by default to 10000×16 bytes (roughly 156KB) of buffer space. To date, there have been neither any reports from users nor any results from our own extensive tests suggesting that either of these compile-time limits should be increased.

- **MaxNoOfConcurrentScans**

This parameter is used to control the number of parallel scans that can be performed in the cluster. Each transaction coordinator can handle the number of parallel scans defined for this parameter. Each scan query is performed by scanning all partitions in parallel. Each partition scan uses a scan record in the node where the partition is located, the number of records being the value of this parameter times the number of nodes. The cluster should be able to sustain `MaxNoOfConcurrentScans` scans concurrently from all nodes in the cluster.

Scans are actually performed in two cases. The first of these cases occurs when no hash or ordered indexes exists to handle the query, in which case the query is executed by performing a full table scan. The second case is encountered when there is no hash index to support the query but there is an ordered index. Using the ordered index means executing a parallel range scan. The order is kept on the local partitions only, so it is necessary to perform the index scan on all partitions.

The default value of `MaxNoOfConcurrentScans` is 256. The maximum value is 500.

- **MaxNoOfLocalScans**
Specifies the number of local scan records if many scans are not fully parallelized. If the number of local scan records is not provided, it is calculated as the product of `MaxNoOfConcurrentScans` and the number of data nodes in the system. The minimum value is 32.
- **BatchSizePerLocalScan**
This parameter is used to calculate the number of lock records which must be there to handle many concurrent scan operations.
The default value is 64; this value has a strong connection to the `ScanBatchSize` defined in the SQL nodes.
- **LongMessageBuffer**
This is an internal buffer used for passing messages within individual nodes and between nodes. Although it is highly unlikely that this would need to be changed, it is configurable. By default, it is set to 1MB.

Memory Allocation

MaxAllocate

This is the maximum size of the memory unit to use when allocating memory for tables. In cases where `NDB` gives `OUT OF MEMORY` errors, but it is evident by examining the cluster logs or the output of `DUMP 1000` (see `DUMP 1000`) that all available memory has not yet been used, you can increase the value of this parameter (or `MaxNoOfTables`, or both) in order to cause `NDB` to make sufficient memory available.

This parameter was introduced in MySQL 5.1.20, and in MySQL Cluster 5.1 Carrier Grade Edition, in MySQL 5.1.15-ndb-6.1.12 and MySQL 5.1.19-ndb-6.2.3.

Logging and checkpointing. These `[NDBD]` parameters control log and checkpoint behavior.

- **NoOfFragmentLogFiles**
This parameter sets the number of REDO log files for the node, and thus the amount of space allocated to REDO logging. Because the REDO log files are organized in a ring, it is extremely important that the first and last log files in the set (sometimes referred to as the “head” and “tail” log files, respectively) do not meet. When these approach one another too closely, the node begins aborting all transactions encompassing updates due to a lack of room for new log records.

A REDO log record is not removed until three local checkpoints have been completed since that log record was inserted. Checkpointing frequency is determined by its own set of configuration parameters discussed elsewhere in this chapter.

How these parameters interact and proposals for how to configure them are discussed in [Section 16.4.6, “Configuring Parameters for Local Checkpoints”](#).

The default parameter value is 16, which means 16 sets of 4 16MB files for a total of 1024MB. In other words, REDO log space must be allocated in blocks of 64MB. In scenarios requiring a great many updates, the value for `NoOfFragmentLogFiles` may

need to be set as high as 300 or even higher to provide sufficient space for REDO logs.

If the checkpointing is slow and there are so many writes to the database that the log files are full and the log tail cannot be cut without jeopardizing recovery, all updating transactions are aborted with internal error code 410 (**Out of log file space temporarily**). This condition prevails until a checkpoint has completed and the log tail can be moved forward.

Important

This parameter cannot be changed “on the fly”; you must restart the node using `--initial`. If you wish to change this value for a running cluster, you can do so via a rolling node restart.

MySQL Cluster 5.1 Carrier Grade Edition

The following information applies to users of MySQL Cluster 5.1 Carrier Grade Edition only. For more information about MySQL Cluster 5.1 Carrier Grade Edition, see Section 16.2, “MySQL Cluster 5.1 Carrier Grade Edition”.

FragmentLogFileSize

Setting this parameter allows you to control directly the size of redo log files. The default is **16M**. This parameter was added in MySQL 5.1.15-ndb-6.1.11.

The following information applies to all MySQL Cluster users.

MaxNoOfOpenFiles

This parameter sets a ceiling on how many internal threads to allocate for open files. *Any situation requiring a change in this parameter should be reported as a bug.*

The default value is 40.

InitialNoOfOpenFiles

This parameter sets the initial number of internal threads to allocate for open files.

The default value is 27.

MaxNoOfSavedMessages

This parameter sets the maximum number of trace files that are kept before overwriting old ones. Trace files are generated when, for whatever reason, the node crashes.

The default is 25 trace files.

Metadata objects. The next set of **[NDBD]** parameters defines pool sizes for metadata objects, used to define the maximum number of attributes, tables, indexes, and trigger objects used by indexes, events, and replication between clusters. Note that these act merely as “suggestions” to the cluster, and any that are not specified revert to the default values shown.

MaxNoOfAttributes

Defines the number of attributes that can be defined in the cluster.

The default value is 1000, with the minimum possible value being 32. The maximum is 4294967039. Each attribute consumes around 200 bytes of storage per node due to the fact that all metadata is fully replicated on the servers.

When setting **MaxNoOfAttributes**, it is important to prepare in advance for any **ALTER TABLE** statements that you might want to perform in the future. This is due to the fact, during the execution of **ALTER TABLE** on a Cluster table, 3 times the number of attributes as in the original table are used. For example, if a table requires 100 attributes, and you want to be able to alter it later, you need to set the value of **MaxNoOfAttributes** to 300. Assuming that you can create all desired tables without any problems, a good rule of thumb is to add two times the number of attributes in the largest table to **MaxNoOfAttributes** to be sure. You

should also verify that this number is sufficient by trying an actual `ALTER TABLE` after configuring the parameter. If this is not successful, increase `MaxNoOfAttributes` by another multiple of the original value and test it again.

- `MaxNoOfTables`

A table object is allocated for each table, unique hash index, and ordered index. This parameter sets the maximum number of table objects for the cluster as a whole.

For each attribute that has a `BLOB` data type an extra table is used to store most of the `BLOB` data. These tables also must be taken into account when defining the total number of tables.

The default value of this parameter is 128. The minimum is 8 and the maximum is 1600. Each table object consumes approximately 20KB per node.

- `MaxNoOfOrderedIndexes`

For each ordered index in the cluster, an object is allocated describing what is being indexed and its storage segments. By default, each index so defined also defines an ordered index. Each unique index and primary key has both an ordered index and a hash index.

The default value of this parameter is 128. Each object consumes approximately 10KB of data per node.

- `MaxNoOfUniqueHashIndexes`

For each unique index that is not a primary key, a special table is allocated that maps the unique key to the primary key of the indexed table. By default, an ordered index is also defined for each unique index. To prevent this, you must specify the `USING HASH` option when defining the unique index.

The default value is 64. Each index consumes approximately 15KB per node.

- `MaxNoOfTriggers`

Internal update, insert, and delete triggers are allocated for each unique hash index. (This means that three triggers are created for each unique hash index.) However, an *ordered* index requires only a single trigger object. Backups also use three trigger objects for each normal table in the cluster.

Replication between clusters also makes use of internal triggers.

This parameter sets the maximum number of trigger objects in the cluster.

The default value is 768.

- `MaxNoOfIndexes`

This parameter is deprecated in MySQL 5.1; you should use `MaxNoOfOrderedIndexes` and `MaxNoOfUniqueHashIndexes` instead.

This parameter is used only by unique hash indexes. There needs to be one record in this pool for each unique hash index defined in the cluster.

The default value of this parameter is 128.

Boolean parameters. The behavior of data nodes is also affected by a set of `[NDBD]` parameters taking on boolean values. These parameters can each be specified as `TRUE` by setting them equal to `1` or `Y`, and as `FALSE` by setting them equal to `0` or `N`.

- `LockPagesInMainMemory`

For a number of operating systems, including Solaris and Linux, it is possible to lock a process into memory and so avoid any swapping to disk. This can be used to help guarantee the cluster's real-time characteristics.

Beginning with MySQL 5.1.15 (MySQL Cluster 5.1 Carrier Grade Edition: MySQL 5.1.15-ndb-6.1.1), this parameter takes one of the integer values `0`, `1`, or `2`, which act as follows:

- `0`: Disables locking. This is the default value.
- `1`: Performs the lock after allocating memory for the process.
- `2`: Performs the lock before memory for the process is allocated.

Previously, this parameter was a Boolean. `0` or `false` was the default setting, and disabled locking. `1` or `true` enabled locking of the process after its memory was allocated.

Important

Beginning with MySQL 5.1.15 (MySQL Cluster 5.1 Carrier Grade Edition: MySQL 5.1.15-ndb-6.1.1), it is no longer possible to use `true` or `false` for the value of this parameter; when upgrading from a previous version, you must change the value to `0`, `1`, or `2`.

StopOnError

This parameter specifies whether an `ndbd` process should exit or perform an automatic restart when an error condition is encountered.

This feature is enabled by default.

Diskless

It is possible to specify MySQL Cluster tables as *diskless*, meaning that tables are not checkpointed to disk and that no logging occurs. Such tables exist only in main memory. A consequence of using diskless tables is that neither the tables nor the records in those tables survive a crash. However, when operating in diskless mode, it is possible to run `ndbd` on a diskless computer.

Important

This feature causes the *entire* cluster to operate in diskless mode.

When this feature is enabled, Cluster online backup is disabled. In addition, a partial start of the cluster is not possible.

`Diskless` is disabled by default.

ODirect

Enabling this parameter causes `NDB` to attempt using `O_DIRECT` writes for LCP, backups, and redo logs, often lowering `kswapd` and CPU usage.

Warning

When using MySQL Cluster or MySQL Cluster 5.1 Carrier Grade Edition on Linux, `ODirect` should be enabled for 2.6 or newer kernels.

This parameter was added in the following releases:

- MySQL 5.1.20
- MySQL 5.1.15-ndb-6.1.11
- MySQL 5.1.19-ndb-6.2.3
- MySQL 5.1.19-ndb-6.3.0

`ODirect` is disabled by default.

RestartOnErrorInsert

This feature is accessible only when building the debug version where it is possible to insert errors in the execution of individual blocks of code as part of testing.

This feature is disabled by default.

Controlling Timeouts, Intervals, and Disk Paging

There are a number of [\[NDBD\]](#) parameters specifying timeouts and intervals between various actions in Cluster data nodes. Most of the timeout values are specified in milliseconds. Any exceptions to this are mentioned where applicable.

- ### TimeBetweenWatchDogCheck

To prevent the main thread from getting stuck in an endless loop at some point, a “watchdog” thread checks the main thread. This parameter specifies the number of milliseconds between checks. If the process remains in the same state after three checks, the watchdog thread terminates it.

This parameter can easily be changed for purposes of experimentation or to adapt to local conditions. It can be specified on a per-node basis although there seems to be little reason for doing so.

The default timeout is 6000 milliseconds (6 seconds).

- ### TimeBetweenWatchDogCheckInitial

This is similar to the [TimeBetweenWatchDogCheck](#) parameter, except that [TimeBetweenWatchDogCheckInitial](#) controls the amount of time that passes between execution checks inside a database node in the early start phases during which memory is allocated.

The default timeout is 6000 milliseconds (6 seconds).

This parameter was added in MySQL 5.1.20.

- ### StartPartialTimeout

This parameter specifies how long the Cluster waits for all data nodes to come up before the cluster initialization routine is invoked. This timeout is used to avoid a partial Cluster startup whenever possible.

The default value is 30000 milliseconds (30 seconds). 0 disables the timeout, in which case the cluster may start only if all nodes are available.

- ### StartPartitionedTimeout

If the cluster is ready to start after waiting for [StartPartialTimeout](#) milliseconds but is still possibly in a partitioned state, the cluster waits until this timeout has also passed.

The default timeout is 60000 milliseconds (60 seconds).

- ### StartFailureTimeout

If a data node has not completed its startup sequence within the time specified by this parameter, the node startup fails. Setting this parameter to 0 (the default value) means that no data node timeout is applied.

For nonzero values, this parameter is measured in milliseconds. For data nodes containing extremely large amounts of data, this parameter should be increased. For example, in the case of a data node containing several gigabytes of data, a period as long as 10–15 minutes (that is, 600000 to 1000000 milliseconds) might be required to perform a node restart.

- ### HeartbeatIntervalDbDb

One of the primary methods of discovering failed nodes is by the use of heartbeats. This parameter states how often heartbeat signals are sent and how often to expect to receive them. After missing three heartbeat intervals in a row, the node is declared dead. Thus, the maximum time for discovering a failure through the heartbeat mechanism is four times the heartbeat interval.

The default heartbeat interval is 1500 milliseconds (1.5 seconds). This parameter must not be changed drastically and should not vary widely between nodes. If one node uses 5000 milliseconds and the node watching it uses 1000 milliseconds, obviously the node will be declared dead very quickly. This parameter can be changed during an online software upgrade, but only in small increments.

- **HeartbeatIntervalDbApi**

Each data node sends heartbeat signals to each MySQL server (SQL node) to ensure that it remains in contact. If a MySQL server fails to send a heartbeat in time it is declared “dead,” in which case all ongoing transactions are completed and all resources released. The SQL node cannot reconnect until all activities initiated by the previous MySQL instance have been completed. The three-heartbeat criteria for this determination are the same as described for **HeartbeatIntervalDbDb**.

The default interval is 1500 milliseconds (1.5 seconds). This interval can vary between individual data nodes because each data node watches the MySQL servers connected to it, independently of all other data nodes.

- **TimeBetweenLocalCheckpoints**

This parameter is an exception in that it does not specify a time to wait before starting a new local checkpoint; rather, it is used to ensure that local checkpoints are not performed in a cluster where relatively few updates are taking place. In most clusters with high update rates, it is likely that a new local checkpoint is started immediately after the previous one has been completed.

The size of all write operations executed since the start of the previous local checkpoints is added. This parameter is also exceptional in that it is specified as the base-2 logarithm of the number of 4-byte words, so that the default value 20 means 4MB (4×2^{20}) of write operations, 21 would mean 8MB, and so on up to a maximum value of 31, which equates to 8GB of write operations.

All the write operations in the cluster are added together. Setting **TimeBetweenLocalCheckpoints** to 6 or less means that local checkpoints will be executed continuously without pause, independent of the cluster's workload.

- **TimeBetweenGlobalCheckpoints**

When a transaction is committed, it is committed in main memory in all nodes on which the data is mirrored. However, transaction log records are not flushed to disk as part of the commit. The reasoning behind this behavior is that having the transaction safely committed on at least two autonomous host machines should meet reasonable standards for durability.

It is also important to ensure that even the worst of cases — a complete crash of the cluster — is handled properly. To guarantee that this happens, all transactions taking place within a given interval are put into a global checkpoint, which can be thought of as a set of committed transactions that has been flushed to disk. In other words, as part of the commit process, a transaction is placed in a global checkpoint group. Later, this group's log records are flushed to disk, and then the entire group of transactions is safely committed to disk on all computers in the cluster.

This parameter defines the interval between global checkpoints. The default is 2000 milliseconds.

- **MySQL Cluster 5.1 Carrier Grade Edition**

The following information applies to users of MySQL Cluster 5.1 Carrier Grade Edition only. For more information about MySQL Cluster 5.1 Carrier Grade Edition, see Section 16.2, “MySQL Cluster 5.1 Carrier Grade Edition”.

TimeBetweenEpochs

This parameter defines the interval between synchronisation epochs for MySQL Cluster Replication. The default value is 100 milliseconds.

TimeBetweenEpochs is part of the implementation of “micro-GCPs”, which can be used to improve the performance of MySQL Cluster Replication. This parameter was introduced in MySQL-5.1.22-ndb-6.2.5 and MySQL 5.1.22-ndb-6.3.2.

The following information applies to all MySQL Cluster users.

- **TimeBetweenInactiveTransactionAbortCheck**

Timeout handling is performed by checking a timer on each transaction once for every interval specified by this parameter. Thus, if this parameter is set to 1000 milliseconds, every transaction will be checked for timing out once per second.

The default value is 1000 milliseconds (1 second).

- **TransactionInactiveTimeout**

This parameter states the maximum time that is permitted to lapse between operations in the same transaction before the transaction is aborted.

The default for this parameter is zero (no timeout). For a real-time database that needs to ensure that no transaction keeps locks for too long, this parameter should be set to a much smaller value. The unit is milliseconds.

- **TransactionDeadlockDetectionTimeout**

When a node executes a query involving a transaction, the node waits for the other nodes in the cluster to respond before continuing. A failure to respond can occur for any of the following reasons:

- The node is “dead”
- The operation has entered a lock queue
- The node requested to perform the action could be heavily overloaded.

This timeout parameter states how long the transaction coordinator waits for query execution by another node before aborting the transaction, and is important for both node failure handling and deadlock detection. In MySQL 5.1.10 and earlier versions, setting it too high could cause undesirable behavior in situations involving deadlocks and node failure. Beginning with MySQL 5.1.11, active transactions occurring during node failures are actively aborted by the Cluster Transaction Coordinator, and so high settings are no longer an issue with this parameter.

The default timeout value is 1200 milliseconds (1.2 seconds).

- **DiskSyncSize**

This is the maximum number of bytes to store before flushing data to a local checkpoint file.

The default value is 4M (4 megabytes).

This parameter was added in MySQL 5.1.12.

- **DiskCheckpointSpeed**

The amount of data, in bytes per second, that is sent to disk during a local checkpoint.

The default value is 10M (10 megabytes per second).

This parameter was added in MySQL 5.1.12.

- **DiskCheckpointSpeedInRestart**

The amount of data, in bytes per second, that is sent to disk during a local checkpoint as part of a restart operation.

The default value is 100M (100 megabytes per second).

This parameter was added in MySQL 5.1.12.

- **NoOfDiskPagesToDiskAfterRestartTUP**

When executing a local checkpoint, the algorithm flushes all data pages to disk. Merely doing so as quickly as possible without any moderation is likely to impose excessive loads on processors, networks, and disks. To control the write speed, this parameter specifies how many pages per 100 milliseconds are to be written. In this context, a “page” is defined as 8KB. This parameter is specified in units of 80KB per second, so setting `NoOfDiskPagesToDiskAfterRestartTUP` to a value of `20` entails writing 1.6MB in data pages to disk each second during a local checkpoint. This value includes the writing of UNDO log records for data pages. That is, this parameter handles the limitation of writes from data memory. (See the entry for `IndexMemory` for information about index pages.)

In short, this parameter specifies how quickly to execute local checkpoints. It operates in conjunction with `NoOfFragmentLogFiles`, `DataMemory`, and `IndexMemory`.

For more information about the interaction between these parameters and possible strategies for choosing appropriate values for them, see [Section 16.4.6, “Configuring Parameters for Local Checkpoints”](#).

The default value is 40 (3.2MB of data pages per second).

Note

This parameter is deprecated as of MySQL 5.1.6. For MySQL 5.1.12 and later versions, use `DiskCheckpointSpeed` and `DiskSyncSize` instead.

- `NoOfDiskPagesToDiskAfterRestartACC`

This parameter uses the same units as `NoOfDiskPagesToDiskAfterRestartTUP` and acts in a similar fashion, but limits the speed of writing index pages from index memory.

The default value of this parameter is 20 (1.6MB of index memory pages per second).

Note

This parameter is deprecated as of MySQL 5.1.6. For MySQL 5.1.12 and later versions, use `DiskCheckpointSpeed` and `DiskSyncSize`.

- `NoOfDiskPagesToDiskDuringRestartTUP`

This parameter is used in a fashion similar to `NoOfDiskPagesToDiskAfterRestartTUP` and `NoOfDiskPagesToDiskAfterRestartACC`, only it does so with regard to local checkpoints executed in the node when a node is restarting. A local checkpoint is always performed as part of all node restarts. During a node restart it is possible to write to disk at a higher speed than at other times, because fewer activities are being performed in the node.

This parameter covers pages written from data memory.

The default value is 40 (3.2MB per second).

Note

This parameter is deprecated as of MySQL 5.1.6. For MySQL 5.1.12 and later versions, use `DiskCheckpointSpeedInRestart` and `DiskSyncSize`.

- `NoOfDiskPagesToDiskDuringRestartACC`

Controls the number of index memory pages that can be written to disk during the local checkpoint phase of a node restart.

As with `NoOfDiskPagesToDiskAfterRestartTUP` and `NoOfDiskPagesToDiskAfterRestartACC`, values for this parameter are expressed in terms of 8KB pages written per 100 milliseconds (80KB/second).

The default value is 20 (1.6MB per second).

Note

This parameter is deprecated as of MySQL 5.1.6. For MySQL 5.1.12 and later versions, use `DiskCheckpointSpeedInRestart` and `DiskSyncSize`.

- **ArbitrationTimeout**

This parameter specifies how long data nodes wait for a response from the arbitrator to an arbitration message. If this is exceeded, the network is assumed to have split.

The default value is 1000 milliseconds (1 second).

Buffering and logging. Several [\[NDBD\]](#) configuration parameters enable the advanced user to have more control over the resources used by node processes and to adjust various buffer sizes at need.

These buffers are used as front ends to the file system when writing log records to disk. If the node is running in diskless mode, these parameters can be set to their minimum values without penalty due to the fact that disk writes are “faked” by the [NDB](#) storage engine's filesystem abstraction layer.

- **UndoIndexBuffer**

The UNDO index buffer, whose size is set by this parameter, is used during local checkpoints. The [NDB](#) storage engine uses a recovery scheme based on checkpoint consistency in conjunction with an operational REDO log. To produce a consistent checkpoint without blocking the entire system for writes, UNDO logging is done while performing the local checkpoint. UNDO logging is activated on a single table fragment at a time. This optimization is possible because tables are stored entirely in main memory.

The UNDO index buffer is used for the updates on the primary key hash index. Inserts and deletes rearrange the hash index; the [NDB](#) storage engine writes UNDO log records that map all physical changes to an index page so that they can be undone at system restart. It also logs all active insert operations for each fragment at the start of a local checkpoint.

Reads and updates set lock bits and update a header in the hash index entry. These changes are handled by the page-writing algorithm to ensure that these operations need no UNDO logging.

This buffer is 2MB by default. The minimum value is 1MB, which is sufficient for most applications. For applications doing extremely large or numerous inserts and deletes together with large transactions and large primary keys, it may be necessary to increase the size of this buffer. If this buffer is too small, the [NDB](#) storage engine issues internal error code 677 ([Index UNDO buffers overloaded](#)).

Important

It is not safe to decrease the value of this parameter during a rolling restart.

- **UndoDataBuffer**

This parameter sets the size of the UNDO data buffer, which performs a function similar to that of the UNDO index buffer, except the UNDO data buffer is used with regard to data memory rather than index memory. This buffer is used during the local checkpoint phase of a fragment for inserts, deletes, and updates.

Because UNDO log entries tend to grow larger as more operations are logged, this buffer is also larger than its index memory counterpart, with a default value of 16MB.

This amount of memory may be unnecessarily large for some applications. In such cases, it is possible to decrease this size to a minimum of 1MB.

It is rarely necessary to increase the size of this buffer. If there is such a need, it is a good idea to check whether the disks can actually handle the load caused by database update activity. A lack of sufficient disk space cannot be overcome by increasing the size of this buffer.

If this buffer is too small and gets congested, the [NDB](#) storage engine issues internal error code 891 ([DATA UNDO BUFFERS OVERLOADED](#)).

Important

It is not safe to decrease the value of this parameter during a rolling restart.

RedoBuffer

All update activities also need to be logged. The REDO log makes it possible to replay these updates whenever the system is restarted. The NDB recovery algorithm uses a “fuzzy” checkpoint of the data together with the UNDO log, and then applies the REDO log to play back all changes up to the restoration point.

`RedoBuffer` sets the size of the buffer in which the REDO log is written, and is 8MB by default. The minimum value is 1MB.

If this buffer is too small, the NDB storage engine issues error code 1221 (`REDO log buffers overloaded`).

Important

It is not safe to decrease the value of this parameter during a rolling restart.

Controlling log messages. In managing the cluster, it is very important to be able to control the number of log messages sent for various event types to `stdout`. For each event category, there are 16 possible event levels (numbered 0 through 15). Setting event reporting for a given event category to level 15 means all event reports in that category are sent to `stdout`; setting it to 0 means that there will be no event reports made in that category.

By default, only the startup message is sent to `stdout`, with the remaining event reporting level defaults being set to 0. The reason for this is that these messages are also sent to the management server's cluster log.

An analogous set of levels can be set for the management client to determine which event levels to record in the cluster log.

- `LogLevelStartup`
The reporting level for events generated during startup of the process.
The default level is 1.
- `LogLevelShutdown`
The reporting level for events generated as part of graceful shutdown of a node.
The default level is 0.
- `LogLevelStatistic`
The reporting level for statistical events such as number of primary key reads, number of updates, number of inserts, information relating to buffer usage, and so on.
The default level is 0.
- `LogLevelCheckpoint`
The reporting level for events generated by local and global checkpoints.
The default level is 0.
- `LogLevelNodeRestart`
The reporting level for events generated during node restart.
The default level is 0.
- `LogLevelConnection`
The reporting level for events generated by connections between cluster nodes.

The default level is 0.

- **LogLevelError**

The reporting level for events generated by errors and warnings by the cluster as a whole. These errors do not cause any node failure but are still considered worth reporting.

The default level is 0.

- **LogLevelCongestion**

The reporting level for events generated by congestion. These errors do not cause node failure but are still considered worth reporting.

The default level is 0.

- **LogLevelInfo**

The reporting level for events generated for information about the general state of the cluster.

The default level is 0.

- **MemReportFrequency**

This parameter controls how often data node memory usage reports are recorded in the cluster log; it is an integer value representing the number of seconds between reports.

Each data node's data memory and index memory usage is logged as both a percentage and a number of 32 KB pages of the **DataMemory** and **IndexMemory**, respectively, set in the **config.ini** file. For example, if **DataMemory** is equal to 100 MB, and a given data node is using 50 MB for data memory storage, the corresponding line in the cluster log might look like this:

```
2006-12-24 01:18:16 [MgmSrvr] INFO -- Node 2: Data usage is 50%(1280 32K pages of total 2560)
```

MemReportFrequency is not a required parameter. If used, it can be set for all cluster data nodes in the **[NDBD DEFAULT]** section of **config.ini**, and can also be set or overridden for individual data nodes in the corresponding **[NDBD]** sections of the configuration file. The minimum value — which is also the default value — is 0, in which case memory reports are logged only when memory usage reaches certain percentages (80%, 90%, and 100%), as mentioned in the discussion of statistics events in [Section 16.7.3.2, “Log Events”](#).

This parameter was added in MySQL Cluster 5.1.16. (MySQL Cluster 5.1 Carrier Grade Edition: MySQL Cluster 5.1.14-ndb-6.1.0).

Backup parameters. The **[NDBD]** parameters discussed in this section define memory buffers set aside for execution of online backups.

- **BackupDataBufferSize**

In creating a backup, there are two buffers used for sending data to the disk. The backup data buffer is used to fill in data recorded by scanning a node's tables. Once this buffer has been filled to the level specified as **BackupWriteSize** (see below), the pages are sent to disk. While flushing data to disk, the backup process can continue filling this buffer until it runs out of space. When this happens, the backup process pauses the scan and waits until some disk writes have completed freed up memory so that scanning may continue.

The default value is 2MB.

- **BackupLogBufferSize**

The backup log buffer fulfills a role similar to that played by the backup data buffer, except that it is used for generating a log of all

table writes made during execution of the backup. The same principles apply for writing these pages as with the backup data buffer, except that when there is no more space in the backup log buffer, the backup fails. For that reason, the size of the backup log buffer must be large enough to handle the load caused by write activities while the backup is being made. See [Section 16.8.4, “Configuration for Cluster Backup”](#).

The default value for this parameter should be sufficient for most applications. In fact, it is more likely for a backup failure to be caused by insufficient disk write speed than it is for the backup log buffer to become full. If the disk subsystem is not configured for the write load caused by applications, the cluster is unlikely to be able to perform the desired operations.

It is preferable to configure cluster nodes in such a manner that the processor becomes the bottleneck rather than the disks or the network connections.

The default value is 2MB.

- **BackupMemory**

This parameter is simply the sum of [BackupDataBufferSize](#) and [BackupLogBufferSize](#).

The default value is 2MB + 2MB = 4MB.

Important

If [BackupDataBufferSize](#) and [BackupLogBufferSize](#) taken together exceed 4MB, then this parameter must be set explicitly in the `config.ini` file to their sum.

- **MySQL Cluster 5.1 Carrier Grade Edition**

The following information applies to users of MySQL Cluster 5.1 Carrier Grade Edition only. For more information about MySQL Cluster 5.1 Carrier Grade Edition, see [Section 16.2, “MySQL Cluster 5.1 Carrier Grade Edition”](#).

This parameter controls how often backup status reports are issued in the management client during a backup, as well as how often such reports are written to the cluster log (provided cluster event logging is configured to allow it — see [Section 16.4.4.5, “Defining Data Nodes”](#) []). [BackupReportFrequency](#) represents the time in seconds between backup status reports.

The default value is 0.

This parameter was added in MySQL 5.1.19-ndb-6.2.3.

The following information applies to all MySQL Cluster users.

- **BackupWriteSize**

This parameter specifies the default size of messages written to disk by the backup log and backup data buffers.

The default value is 32KB.

- **BackupMaxWriteSize**

This parameter specifies the maximum size of messages written to disk by the backup log and backup data buffers.

The default value is 256KB.

Important

When specifying these parameters, the following relationships must hold true. Otherwise, the data node will be unable to start.

- [BackupDataBufferSize](#) >= [BackupWriteSize](#) + 188KB

- `BackupLogBufferSize >= BackupWriteSize + 16KB`
- `BackupMaxWriteSize >= BackupWriteSize`

16.4.4.6. Defining SQL and Other API Nodes

The `[MYSQLD]` and `[API]` sections in the `config.ini` file define the behavior of the MySQL servers (SQL nodes) and other applications (API nodes) used to access cluster data. None of the parameters shown is required. If no computer or host name is provided, any host can use this SQL or API node.

Generally speaking, a `[MYSQLD]` section is used to indicate a MySQL server providing an SQL interface to the cluster, and an `[API]` section is used for applications other than `mysqld` processes accessing cluster data, but the two designations are actually synonymous; you can, for instance, list parameters for a MySQL server acting as an SQL node in an `[API]` section.

- **Id**

The **Id** value is used to identify the node in all cluster internal messages. It must be an integer in the range 1 to 63 inclusive, and must be unique among all node IDs within the cluster.

- **ExecuteOnComputer**

This refers to the **Id** set for one of the computers (hosts) defined in a `[COMPUTER]` section of the configuration file.

- **HostName**

Specifying this parameter defines the hostname of the computer on which the SQL node (API node) is to reside. To specify a host-name other than `localhost`, either this parameter or **ExecuteOnComputer** is required.

- **ArbitrationRank**

This parameter defines which nodes can act as arbitrators. Both MGM nodes and SQL nodes can be arbitrators. A value of 0 means that the given node is never used as an arbitrator, a value of 1 gives the node high priority as an arbitrator, and a value of 2 gives it low priority. A normal configuration uses the management server as arbitrator, setting its **ArbitrationRank** to 1 (the default) and those for all SQL nodes to 0.

Beginning with MySQL 5.1.16 (*MySQL Cluster 5.1 Carrier Grade Edition: MySQL 5.1.15-ndb-6.1.3*), it is possible to disable arbitration completely by setting **ArbitrationRank** to 0 on all management and SQL nodes.

- **ArbitrationDelay**

Setting this parameter to any other value than 0 (the default) means that responses by the arbitrator to arbitration requests will be delayed by the stated number of milliseconds. It is usually not necessary to change this value.

- **BatchByteSize**

For queries that are translated into full table scans or range scans on indexes, it is important for best performance to fetch records in properly sized batches. It is possible to set the proper size both in terms of number of records (**BatchSize**) and in terms of bytes (**BatchByteSize**). The actual batch size is limited by both parameters.

The speed at which queries are performed can vary by more than 40% depending upon how this parameter is set. In future releases, MySQL Server will make educated guesses on how to set parameters relating to batch size, based on the query type.

This parameter is measured in bytes and by default is equal to 32KB.

- **BatchSize**

This parameter is measured in number of records and is by default set to 64. The maximum size is 992.

- **MaxScanBatchSize**

The batch size is the size of each batch sent from each data node. Most scans are performed in parallel to protect the MySQL Server from receiving too much data from many nodes in parallel; this parameter sets a limit to the total batch size over all nodes.

The default value of this parameter is set to 256KB. Its maximum size is 16MB.

You can obtain some information from a MySQL server running as a Cluster SQL node using `SHOW STATUS` in the `mysql` client, as shown here:

```
mysql> SHOW STATUS LIKE 'ndb%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_cluster_node_id | 5 |
| Ndb_config_from_host | 192.168.0.112 |
| Ndb_config_from_port | 1186 |
| Ndb_number_of_storage_nodes | 4 |
+-----+-----+
4 rows in set (0.02 sec)
```

For information about these Cluster system status variables, see [Section 5.2.5, “Status Variables”](#).

16.4.4.7. Cluster TCP/IP Connections

TCP/IP is the default transport mechanism for establishing connections in MySQL Cluster. It is normally not necessary to define connections because Cluster automatically set ups a connection between each of the data nodes, between each data node and all MySQL server nodes, and between each data node and the management server. (For one exception to this rule, see [Section 16.4.4.8, “TCP/IP Connections Using Direct Connections”](#).) `[TCP]` sections in the `config.ini` file explicitly define TCP/IP connections between nodes in the cluster.

It is necessary to define a connection only to override the default connection parameters. In that case, it is necessary to define at least `NodeId1`, `NodeId2`, and the parameters to change.

Important

Any `[TCP]` sections in the `config.ini` file should be listed last, following any other sections in the file. This is not required for a `[TCP DEFAULT]` section. This is a known issue with the way in which the `config.ini` file is read by the cluster management server.

It is also possible to change the default values for these parameters by setting them in the `[TCP DEFAULT]` section.

- **NodeId1, NodeId2**

To identify a connection between two nodes it is necessary to provide their node IDs in the `[TCP]` section of the configuration file. These are the same unique `Id` values for each of these nodes as described in [Section 16.4.4.6, “Defining SQL and Other API Nodes”](#).

- **SendBufferMemory**

TCP transporters use a buffer to store all messages before performing the send call to the operating system. When this buffer reaches 64KB its contents are sent; these are also sent when a round of messages have been executed. To handle temporary overload situations it is also possible to define a bigger send buffer. The default size of the send buffer is 256 KB. The minimum size is 64 KB; the theoretical maximum is 4 GB.

- **SendSignalId**

To be able to retrace a distributed message datagram, it is necessary to identify each message. When this parameter is set to `Y`, message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- **Checksum**

This parameter is a boolean parameter (enabled by setting it to **Y** or **1**, disabled by setting it to **N** or **0**). It is disabled by default. When it is enabled, checksums for all messages are calculated before they placed in the send buffer. This feature ensures that messages are not corrupted while waiting in the send buffer, or by the transport mechanism.

- **PortNumber** (*OBSOLETE*)

This formerly specified the port number to be used for listening for connections from other nodes. This parameter should no longer be used.

- **ReceiveBufferMemory**

Specifies the size of the buffer used when receiving data from the TCP/IP socket. There is seldom any need to change this parameter from its default value of 64 KB, except possibly to save memory. The minimum possible value is 16K; the theoretical maximum is 4G.

16.4.4.8. TCP/IP Connections Using Direct Connections

Setting up a cluster using direct connections between data nodes requires specifying explicitly the crossover IP addresses of the data nodes so connected in the **[TCP]** section of the cluster **config.ini** file.

In the following example, we envision a cluster with at least four hosts, one each for a management server, an SQL node, and two data nodes. The cluster as a whole resides on the **172.23.72.*** subnet of a LAN. In addition to the usual network connections, the two data nodes are connected directly using a standard crossover cable, and communicate with one another directly using IP addresses in the **1.1.0.*** address range as shown:

```
# Management Server
[NDB_MGMD]
Id=1
HostName=172.23.72.20

# SQL Node
[MYSQLD]
Id=2
HostName=172.23.72.21

# Data Nodes
[NDBD]
Id=3
HostName=172.23.72.22

[NDBD]
Id=4
HostName=172.23.72.23

# TCP/IP Connections
[TCP]
NodeId1=3
NodeId2=4
HostName1=1.1.0.1
HostName2=1.1.0.2
```

The **HostNameN** parameter, where **N** is an integer, is used only when specifying direct TCP/IP connections.

The use of direct connections between data nodes can improve the cluster's overall efficiency by allowing the data nodes to bypass an Ethernet device such as a switch, hub, or router, thus cutting down on the cluster's latency. It is important to note that to take the best advantage of direct connections in this fashion with more than two data nodes, you must have a direct connection between each data node and every other data node in the same node group.

16.4.4.9. Shared-Memory Connections

MySQL Cluster attempts to use the shared memory transporter and configure it automatically where possible. **[SHM]** sections in the **config.ini** file explicitly define shared-memory connections between nodes in the cluster. When explicitly defining shared memory as the connection method, it is necessary to define at least **NodeId1**, **NodeId2** and **ShmKey**. All other parameters have default values that should work well in most cases.

■ Important

SHM functionality is considered experimental only. It is not officially supported in any MySQL release series up to and including 5.1. This means that you must determine for yourself or by using our free resources (forums, mailing lists) whether it can be made to work correctly in your specific case.

- **NodeId1, NodeId2**
To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as **NodeId1** and **NodeId2**.
- **ShmKey**
When setting up shared memory segments, a node ID, expressed as an integer, is used to identify uniquely the shared memory segment to use for the communication. There is no default value.
- **ShmSize**
Each SHM connection has a shared memory segment where messages between nodes are placed by the sender and read by the reader. The size of this segment is defined by **ShmSize**. The default value is 1MB.
- **SendSignalId**
To retrace the path of a distributed message, it is necessary to provide each message with a unique identifier. Setting this parameter to **Y** causes these message IDs to be transported over the network as well. This feature is disabled by default in production builds, and enabled in **-debug** builds.
- **Checksum**
This parameter is a boolean (**Y/N**) parameter which is disabled by default. When it is enabled, checksums for all messages are calculated before being placed in the send buffer.

This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

16.4.4.10. SCI Transport Connections

[**SCI**] sections in the **config.ini** file explicitly define SCI (Scalable Coherent Interface) connections between cluster nodes. Using SCI transporters in MySQL Cluster is supported only when the MySQL binaries are built using **--with-ndb-sci=/your/path/to/SCI**. The **path** should point to a directory that contains at a minimum **lib** and **include** directories containing SISI libraries and header files. (See [Section 16.12, “Using High-Speed Interconnects with MySQL Cluster”](#) for more information about SCI.)

In addition, SCI requires specialized hardware.

It is strongly recommended to use SCI Transporters only for communication between **ndbd** processes. Note also that using SCI Transporters means that the **ndbd** processes never sleep. For this reason, SCI Transporters should be used only on machines having at least two CPUs dedicated for use by **ndbd** processes. There should be at least one CPU per **ndbd** process, with at least one CPU left in reserve to handle operating system activities.

- **NodeId1, NodeId2**
To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as **NodeId1** and **NodeId2**.
- **Host1SciId0**
This identifies the SCI node ID on the first Cluster node (identified by **NodeId1**).

- [Host1SciId1](#)

It is possible to set up SCI Transporters for failover between two SCI cards which then should use separate networks between the nodes. This identifies the node ID and the second SCI card to be used on the first node.

- [Host2SciId0](#)

This identifies the SCI node ID on the second Cluster node (identified by [NodeId2](#)).

- [Host2SciId1](#)

When using two SCI cards to provide failover, this parameter identifies the second SCI card to be used on the second node.

- [SharedBufferSize](#)

Each SCI transporter has a shared memory segment used for communication between the two nodes. Setting the size of this segment to the default value of 1MB should be sufficient for most applications. Using a smaller value can lead to problems when performing many parallel inserts; if the shared buffer is too small, this can also result in a crash of the [ndbd](#) process.

- [SendLimit](#)

A small buffer in front of the SCI media stores messages before transmitting them over the SCI network. By default, this is set to 8KB. Our benchmarks show that performance is best at 64KB but 16KB reaches within a few percent of this, and there was little if any advantage to increasing it beyond 8KB.

- [SendSignalId](#)

To trace a distributed message it is necessary to identify each message uniquely. When this parameter is set to [Y](#), message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in [-debug](#) builds.

- [Checksum](#)

This parameter is a boolean value, and is disabled by default. When [Checksum](#) is enabled, checksums are calculated for all messages before they are placed in the send buffer. This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

16.4.5. Overview of Cluster Configuration Parameters

The next three sections provide summary tables of MySQL Cluster configuration parameters used in the [config.ini](#) file to govern the cluster's functioning. Each table lists the parameters for one of the Cluster node process types ([ndbd](#), [ndb_mgmd](#), and [mysqld](#)), and includes the parameter's type as well as its default, minimum, and maximum values as applicable.

It is also stated what type of restart is required (node restart or system restart) — and whether the restart must be done with [-initial](#) — to change the value of a given configuration parameter. This information is provided in each table's **Restart Type** column, which contains one of the values shown in this list:

- [N](#): Node Restart
- [IN](#): Initial Node Restart
- [S](#): System Restart
- [IS](#): Initial System Restart

When performing a node restart or an initial node restart, all of the cluster's data nodes must be restarted in turn (also referred to as a *rolling restart*). It is possible to update cluster configuration parameters marked [N](#) or [IN](#) online — that is, without shutting down the cluster — in this fashion. An initial node restart requires restarting each [ndbd](#) process with the [--initial](#) option.

A system restart requires a complete shutdown and restart of the entire cluster. An initial system restart requires taking a backup of the

cluster, wiping the cluster filesystem after shutdown, and then restoring from the backup following the restart.

In any cluster restart, all of the cluster's management servers must be restarted in order for them to read the updated configuration parameter values.

Important

Values for numeric cluster parameters can generally be increased without any problems, although it is advisable to do so progressively, making such adjustments in relatively small increments. However, decreasing the values of such parameters — particularly those relating to memory usage and disk space — is not to be undertaken lightly, and it is recommended that you do so only following careful planning and testing. In addition, it is the generally the case that parameters relating to memory and disk usage which can be raised using a simple node restart require an initial node restart to be lowered.

Because some of these parameters can be used for configuring more than one type of cluster node, they may appear in more than one of the tables.

(Note that [4294967039](#) — which often appears as a maximum value in these tables — is equal to $2^{32} - 2^8 - 1$.)

16.4.5.1. Data Node Configuration Parameters

The following table provides information about parameters used in the `[NDBD]` or `[NDB_DEFAULT]` sections of a `config.ini` file for configuring MySQL Cluster data nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 16.4.4.5, “Defining Data Nodes”](#).

Restart Type Column Values

- **N**: Node Restart
- **IN**: Initial Node Restart
- **S**: System Restart
- **IS**: Initial System Restart

See [Section 16.4.5, “Overview of Cluster Configuration Parameters”](#), for additional explanations of these abbreviations.

Parameter Name	Type / Unit	Default Value	Minimum Value	Maximum Value	Restart Type
ArbitrationTimeout	milliseconds	3000	10	4294967039	N
BackupDataBufferSize	bytes	2M	0	4294967039	N
BackupDataDir	string	FileSystemPath/BACKUP	N/A	N/A	IN
BackupLogBufferSize	bytes	2M	0	4294967039	N
BackupMemory	bytes	4M	0	4294967039	N
BackupReportFrequency (Added in MySQL 5.1.19-ndb-6.2.3)	seconds	0	0	4294967039	N

16.4.5.2. Management Node Configuration Parameters

The following table provides information about parameters used in the [\[NDB_MGMD\]](#) or [\[MGM\]](#) sections of a [config.ini](#) file for configuring MySQL Cluster management nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 16.4.4.4, “Defining the Management Server”](#).

Restart Type Column Values

- **N**: Node Restart
- **IN**: Initial Node Restart
- **S**: System Restart
- **IS**: Initial System Restart

See [Section 16.4.5, “Overview of Cluster Configuration Parameters”](#), for additional explanations of these abbreviations.

Parameter Name	Type / Units	Default Value	Minimum Value	Maximum Value	Restart Type
ArbitrationDelay	milliseconds	0	0	4294967039	N
ArbitrationRank	integer	1	0	2	N
DataDir	string	./ (ndb_mgmd directory)	N/A	N/A	IN
ExecuteOnComputer	integer				
HostName	string	localhost	N/A	N/A	IN
Id	integer	<i>None</i>	1	63	IN

LogDestination	CON SOL E, SYS LOG, or FIL E	FILE (see Section 16.4.4.4, “Defining the Management Server”)	N/A	N/A	N

16.4.5.3. SQL Node and API Node Configuration Parameters

The following table provides information about parameters used in the [\[SQL\]](#) and [\[API\]](#) sections of a [config.ini](#) file for configuring MySQL Cluster SQL nodes and API nodes. For detailed descriptions and other additional information about each of these parameters, see [Section 16.4.4.6, “Defining SQL and Other API Nodes”](#).

Restart Type Column Values

- **N**: Node Restart
- **IN**: Initial Node Restart
- **S**: System Restart
- **IS**: Initial System Restart

See [Section 16.4.5, “Overview of Cluster Configuration Parameters”](#), for additional explanations of these abbreviations.

Parameter Name	Type / Units	Default Value	Minimum Value	Maximum Value	Restart Type
ArbitrationDelay	milli-seconds	0	0	4294967039	N
ArbitrationRank	integer	1	0	2	N
BatchByteSize	bytes	32K	1K	1M	N
BatchSize	integer	64	1	992	N
ExecuteOnComputer	integer				
HostName	string	localhost	N/A	N/A	IN
Id	integer	<i>None</i>	1	63	IN
MaxScanBatchSize	bytes	256K	32K	16M	N

16.4.6. Configuring Parameters for Local Checkpoints

The parameters discussed in [Logging and Checkpointing](#) and in [Data Memory, Index Memory, and String Memory](#) that are used to configure local checkpoints for a MySQL Cluster do not exist in isolation, but rather are very much interdependent on each other. In this section, we illustrate how these parameters — including [DataMemory](#), [IndexMemory](#), [NoOfDiskPagesToDiskAfterRestartTUP](#), [NoOfDiskPagesToDiskAfterRestartACC](#), and [NoOfFragmentLogFiles](#) — relate to one another in a working Cluster.

Important

The parameters `NoOfDiskPagesToDiskAfterRestartTUP` and `NoOfDiskPagesToDiskAfterRestartACC` were deprecated in MySQL 5.1.6. From MySQL 5.1.6 through 5.1.11, disk writes during LCPs took place at the maximum speed possible. Beginning with MySQL 5.1.12, the speed and throughput for LCPs are controlled using the parameters `DiskSyncSize`, `DiskCheckpointSpeed`, and `DiskCheckpointSpeedInRestart`. See [Section 16.4.4.5, “Defining Data Nodes”](#).

In this example, we assume that our application performs the following numbers of types of operations per hour:

- 50000 selects
- 15000 inserts
- 15000 updates
- 15000 deletes

We also make the following assumptions about the data used in the application:

- We are working with a single table having 40 columns.
- Each column can hold up to 32 bytes of data.
- A typical `UPDATE` run by the application affects the values of 5 columns.
- No `NULL` values are inserted by the application.

A good starting point is to determine the amount of time that should elapse between local checkpoints (LCPs). It worth noting that, in the event of a system restart, it takes 40-60 percent of this interval to execute the REDO log — for example, if the time between LCPs is 5 minutes (300 seconds), then it should take 2 to 3 minutes (120 to 180 seconds) for the REDO log to be read.

The maximum amount of data per node can be assumed to be the size of the `DataMemory` parameter. In this example, we assume that this is 2 GB. The `NoOfDiskPagesToDiskAfterRestartTUP` parameter represents the amount of data to be checkpointed per unit time — however, this parameter is actually expressed as the number of 8K memory pages to be checkpointed per 100 milliseconds. 2 GB per 300 seconds is approximately 6.8 MB per second, or 700 KB per 100 milliseconds, which works out to roughly 85 pages per 100 milliseconds.

Similarly, we can calculate `NoOfDiskPagesToDiskAfterRestartACC` in terms of the time for local checkpoints and the amount of memory required for indexes — that is, the `IndexMemory`. Assuming that we allow 512 MB for indexes, this works out to approximately 20 8-KB pages per 100 milliseconds for this parameter.

Next, we need to determine the number of REDO log files required — that is, fragment log files — the corresponding parameter being `NoOfFragmentLogFiles`. We need to make sure that there are sufficient REDO log files for keeping records for at least 3 local checkpoints. In a production setting, there are always uncertainties — for instance, we cannot be sure that disks always operate at top speed or with maximum throughput. For this reason, it is best to err on the side of caution, so we double our requirement and calculate a number of fragment log files which should be enough to keep records covering 6 local checkpoints.

It is also important to remember that the disk also handles writes to the REDO log, so if you find that the amount of data being written to disk as determined by the values of `NoOfDiskPagesToDiskAfterRestartACC` and `NoOfDiskPagesToDiskAfterRestartTUP` is approaching the amount of disk bandwidth available, you may wish to increase the time between local checkpoints.

Given 5 minutes (300 seconds) per local checkpoint, this means that we need to support writing log records at maximum speed for $6 * 300 = 1800$ seconds. The size of a REDO log record is 72 bytes plus 4 bytes per updated column value plus the maximum size of the updated column, and there is one REDO log record for each table record updated in a transaction, on each node where the data reside. Using the numbers of operations set out previously in this section, we derive the following:

- 50000 select operations per hour yields 0 log records (and thus 0 bytes), since `SELECT` statements are not recorded in the REDO log.
- 15000 `DELETE` statements per hour is approximately 5 delete operations per second. (Since we wish to be conservative in our estimate, we round up here and in the following calculations.) No columns are updated by deletes, so these statements consume only 5 operations * 72 bytes per operation = 360 bytes per second.

- 15000 **UPDATE** statements per hour is roughly the same as 5 updates per second. Each update uses 72 bytes, plus 4 bytes per column * 5 columns updated, plus 32 bytes per column * 5 columns — this works out to $72 + 20 + 160 = 252$ bytes per operation, and multiplying this by 5 operation per second yields 1260 bytes per second.
- 15000 **INSERT** statements per hour is equivalent to 5 insert operations per second. Each insert requires REDO log space of 72 bytes, plus 4 bytes per record * 40 columns, plus 32 bytes per column * 40 columns, which is $72 + 160 + 1280 = 1512$ bytes per operation. This times 5 operations per second yields 7560 bytes per second.

So the total number of REDO log bytes being written per second is approximately $0 + 360 + 1260 + 7560 = 9180$ bytes. Multiplied by 1800 seconds, this yields 16524000 bytes required for REDO logging, or approximately 15.75 MB. The unit used for **NoOfFrag-mentLogFiles** represents a set of 4 16-MB log files — that is, 64 MB. Thus, the minimum value (3) for this parameter is sufficient for the scenario envisioned in this example, since 3 times 64 = 192 MB, or about 12 times what is required; the default value of 8 (or 512 MB) is more than ample in this case.

16.5. Upgrading and Downgrading MySQL Cluster

This portion of the MySQL Cluster chapter covers upgrading and downgrading a MySQL Cluster from one MySQL release to another. It discusses different types of Cluster upgrades and downgrades, and provides a Cluster upgrade/downgrade compatibility matrix (see [Section 16.5.2, “Cluster Upgrade and Downgrade Compatibility”](#)). You are expected already to be familiar with installing and configuring a MySQL Cluster prior to attempting an upgrade or downgrade. See [Section 16.4, “MySQL Cluster Configuration”](#).

For information about upgrading or downgrading between MySQL Cluster 5.1 Carrier Grade Edition releases, or between MySQL Cluster 5.1 Carrier Grade Edition releases and mainline MySQL releases, see the changelogs relating to MySQL Cluster 5.1 Carrier Grade Edition.

This section remains in development, and continues to be updated and expanded.

16.5.1. Performing a Rolling Restart of the Cluster

This section discusses how to perform a *rolling restart* of a MySQL Cluster installation, so called because it involves stopping and starting (or restarting) each node in turn, so that the cluster itself remains operational. This is often done as part of a *rolling upgrade* or *rolling downgrade*, where high availability of the cluster is mandatory and no downtime of the cluster as a whole is permissible. Where we refer to upgrades, the information provided here also generally applies to downgrades as well.

There are a number of reasons why a rolling restart might be desirable:

- **Cluster configuration change.** To make a change in the cluster's configuration, such as adding an SQL node to the cluster, or setting a configuration parameter to a new value.
- **Cluster software upgrade/downgrade.** To upgrade the cluster to a newer version of the MySQL Cluster software (or to downgrade it to an older version). This is usually referred to as a “rolling upgrade” (or “rolling downgrade”, when reverting to an older version of MySQL Cluster).
- **Change on node host.** To make changes in the hardware or operating system on which one or more cluster nodes are running
- **Cluster reset.** To reset the cluster because it has reached an undesirable state
- **Freeing of resources.** To allow memory allocated to a table by successive **INSERT** and **DELETE** operations to be freed for re-use by other Cluster tables

The process for performing a rolling restart may be generalised as follows:

1. Stop all cluster management nodes (**ndb_mgmd** processes), reconfigure them, then restart them
2. Stop, reconfigure, then restart each cluster data node (**ndbd** process) in turn
3. Stop, reconfigure, then restart each cluster SQL node (**mysqld** process) in turn

The specifics for implementing a particular rolling upgrade depend upon the actual changes being made. A more detailed view of the process is presented here:

RESTART TYPE:					
Cluster Configuration Change		Cluster Software Upgrade or Downgrade	Change on Node Host	Cluster Reset	
A. Management node (ndb_mgmd) processes...					
1. Stop all ndb_mgmd processes 2. Make changes in global configuration file(s) 3. Start all ndb_mgmd processes		1. Stop all ndb_mgmd processes 2. Replace each ndb_mgmd binary with new version 3. Start ndb_mgmd processes	1. Stop all ndb_mgmd processes 2. Make desired changes in hardware, operating system, or both 3. Start all ndb_mgmd processes	(OR)	
				1. Stop all ndb_mgmd processes 2. Start all ndb_mgmd processes	Restart all ndb_mgmd processes (optional)
B. For each data node (ndbd) process...					
(OR)		1. Stop ndbd 2. Replace ndbd binary with new version 3. Start ndbd	1. Stop ndbd 2. Make desired changes in hardware, operating system, or both 3. Start ndbd	(OR)	
1. Stop ndbd 2. Start ndbd	Restart ndbd			1. Stop ndbd 2. Start ndbd	Restart ndbd
C. For each SQL node (mysqld) process...					
(OR)		1. Stop mysqld 2. Replace mysqld binary with new version 3. Start mysqld	1. Stop mysqld 2. Make desired changes in hardware, operating system, or both 3. Start mysqld	(OR)	
1. Stop mysqld 2. Start mysqld	Restart mysqld			1. Stop mysqld 2. Start mysqld	Restart mysqld

In the previous diagram, **Stop** and **Start** steps indicate that the process must be stopped completely using a shell command (such as `kill` on most Unix systems) or the management client `STOP` command, then started again from a system shell by invoking the `ndbd` or `ndb_mgmd` executable as appropriate. **Restart** indicates the process may be restarted using the `ndb_mgm` management client `RE-START` command.

Important

When performing an upgrade or downgrade of the cluster software, you *must* upgrade or downgrade the management nodes *first*, then the data nodes, and finally the SQL nodes. Doing so in any other order may leave the cluster in an unus-

■ able state.

16.5.2. Cluster Upgrade and Downgrade Compatibility

This section provides information regarding Cluster software and table file compatibility between differing versions of the MySQL Server for purposes of performing upgrades and downgrades.

Important

Only compatibility between MySQL versions with regard to [NDB Cluster](#) is taken into account in this section, and there are likely other issues to be considered. *As with any other MySQL software upgrade or downgrade, you are strongly encouraged to review the relevant portions of the MySQL Manual for the MySQL versions from which and to which you intend to migrate, before attempting an upgrade or downgrade of the MySQL Cluster software.* See [Section 2.11](#), “Upgrading MySQL”.

The following table shows Cluster upgrade and downgrade compatibility between different versions of the MySQL Server.

**KEY:**

↑↓ Upgrades and downgrades supported

↑ Upgrade only

Notes:

- **4.1 Series:**

You cannot upgrade directly from 4.1.8 to 4.1.10 (or newer); you must first upgrade from 4.1.8 to 4.1.9, then upgrade to 4.1.10. Similarly, you cannot downgrade directly from 4.1.10 (or newer) to 4.1.8; you must first downgrade from 4.1.10 to 4.1.9, then downgrade from 4.1.9 to 4.1.8.

If you wish to upgrade a MySQL Cluster to 4.1.15, you must upgrade to 4.1.14 first, and you must upgrade to 4.1.15 before upgrading to 4.1.16 or newer.

Cluster downgrades from 4.1.15 to 4.1.14 (or earlier versions) are not supported.

Cluster upgrades from MySQL Server versions previous to 4.1.8 are not supported; when upgrading from these, you must dump all **NDB** tables, install the new version of the software, and then reload the tables from the dump.

- **5.0 Series:**

MySQL 5.0.2 was the first public release in this series.

Cluster downgrades from MySQL 5.0 to MySQL 4.1 are not supported.

Cluster downgrades from 5.0.12 to 5.0.11 (or earlier) are not supported.

You cannot restore with **ndb_restore** to a MySQL 5.0 Cluster using a backup made from a Cluster running MySQL 5.1. You must use **mysqldump** in such cases.

There was no public release for MySQL 5.0.23.

- **5.1 Series:**

MySQL 5.1.3 was the first public release in this series.

You cannot downgrade a MySQL 5.1.6 or later Cluster using Disk Data tables to MySQL 5.1.5 or earlier unless you convert all such tables to in-memory Cluster tables first.

MySQL 5.1.8, MySQL 5.1.10, and MySQL 5.1.13 were not released.

Online cluster upgrades and downgrades between MySQL 5.1.11 (or an earlier version) and 5.1.12 (or a later version) are not possible due to major changes in the cluster filesystem. In such cases, you must perform a backup or dump, upgrade (or downgrade) the software, start each data node with **--initial**, and then restore from the backup or dump. You can use **NDB** backup/restore or **mysqldump** for this purpose.

- Online downgrades from MySQL 5.1.14 or later to versions previous to 5.1.14 are not supported due to incompatible changes in the cluster system tables.
- Online upgrades from MySQL 5.1.17 and earlier to 5.1.18 and later are not supported for clusters using replication due to incompatible changes in the **mysql.ndb_apply_status** table. However, it should not be necessary to shut down the cluster entirely, if you follow this modified rolling restart procedure:

1. Stop the management server, update the **ndb_mgmd** binary, then start it again. For multiple management servers, repeat this step for each management server in turn.
2. For each data node in turn: Stop the data node, replace the **ndbd** binary with the new version, then restart the data node. It is not necessary to use **--initial** when restarting any of the data nodes.
3. Stop *all* SQL nodes. Replace the **mysqld** binary with the new version for all SQL nodes, then restart them. It is not necessary to start them one at a time, but they must all be shut down at the same time before starting any of them again using the 5.1.18 (or later) **mysqld**. Otherwise — due to the fact that **mysql.ndb_apply_status** uses the **NDB** storage engine and is thus shared between all SQL nodes — there may be conflicts between MySQL servers using the old and new versions of the table. You can find more information about the changes to **ndb_apply_status** in [Section 16.10.4, “Cluster Replication Schema and Tables”](#).

- The internal specifications for columns in **NDB** tables changed in MySQL 5.1.18 to allow compatibility with future MySQL Cluster releases that are expected to implement online adding and dropping of columns. This change is not backwards compatible with earlier

er MySQL versions.

In order to make tables created in MySQL 5.1.17 and earlier compatible with online adding and dropping of columns when this feature becomes available, it is necessary for MySQL 5.1.18 and later to convert the tables to the new format by following this procedure:

1. Upgrade the MySQL Cluster software on all data, management, and SQL nodes
2. Back up all **NDB** tables
3. Shut down the cluster (all data, management, and SQL nodes)
4. Restart the cluster, starting all data nodes with the `--initial` option (to clear and rebuild the data node filesystems)
5. Restore the tables from backup

This is not necessary for **NDB** tables created in MySQL 5.1.18 and later; such tables will automatically be compatible with online adding and dropping of columns when this feature is introduced.

In order to minimise possible later difficulties, it is strongly advised that the procedure outlined above be followed as soon as possible after upgrading from MySQL 5.1.17 or earlier to MySQL 5.1.18 or later.

For users of MySQL Cluster 5.1 Carrier Grade Edition the relevant versions are as follows:

- **ndb-6.1.x series.** The new table format is implemented beginning with MySQL 5.1.15-ndb-6.1.7.
- **ndb-6.2.x series.** The new table format is implemented beginning with MySQL 5.1.16-ndb-6.2.1.

16.6. Process Management in MySQL Cluster

Understanding how to manage MySQL Cluster requires a knowledge of four essential processes. In the next few sections of this chapter, we cover the roles played by these processes in a cluster, how to use them, and what startup options are available for each of them:

- [Section 16.6.1, “MySQL Server Process Usage for MySQL Cluster”](#)
- [Section 16.6.2, “ndbd — The Storage Engine Node Process”](#)
- [Section 16.6.3, “ndb_mgmd — The Management Server Process”](#)
- [Section 16.6.4, “ndb_mgm — The Management Client Process”](#)

16.6.1. MySQL Server Process Usage for MySQL Cluster

`mysqld` is the traditional MySQL server process. To be used with MySQL Cluster, `mysqld` needs to be built with support for the **NDB Cluster** storage engine, as it is in the precompiled binaries available from <http://dev.mysql.com/downloads/>. If you build MySQL from source, you must invoke `configure` with the `--with-ndbcluster` option to enable **NDB Cluster** storage engine support.

If the `mysqld` binary has been built with Cluster support, the **NDB Cluster** storage engine is still disabled by default. You can use either of two possible options to enable this engine:

- Use `--ndbcluster` as a startup option on the command line when starting `mysqld`.
- Insert a line containing `ndbcluster` in the `[mysqld]` section of your `my.cnf` file.

An easy way to verify that your server is running with the **NDB Cluster** storage engine enabled is to issue the `SHOW ENGINES` statement in the MySQL Monitor (`mysql`). You should see the value **YES** as the **Support** value in the row for **NDBCLUSTER**. If you see **NO** in this row or if there is no such row displayed in the output, you are not running an **NDB-enabled** version of MySQL. If you see **DISABLED** in this row, you need to enable it in either one of the two ways just described.

To read cluster configuration data, the MySQL server requires at a minimum three pieces of information:

- The MySQL server's own cluster node ID
- The hostname or IP address for the management server (MGM node)
- The number of the TCP/IP port on which it can connect to the management server

Node IDs can be allocated dynamically, so it is not strictly necessary to specify them explicitly.

The `mysqld` parameter `ndb-connectstring` is used to specify the connectstring either on the command line when starting `mysqld` or in `my.cnf`. The connectstring contains the hostname or IP address where the management server can be found, as well as the TCP/IP port it uses.

In the following example, `ndb_mgmd.mysql.com` is the host where the management server resides, and the management server listens for cluster messages on port 1186:

```
shell> mysqld --ndbcluster --ndb-connectstring=ndb_mgmd.mysql.com:1186
```

See [Section 16.4.4.2, “The Cluster Connectstring”](#), for more information on connectstrings.

Given this information, the MySQL server will be a full participant in the cluster. (We often refer to a `mysqld` process running in this manner as an SQL node.) It will be fully aware of all cluster data nodes as well as their status, and will establish connections to all data nodes. In this case, it is able to use any data node as a transaction coordinator and to read and update node data.

You can see in the `mysql` client whether a MySQL server is connected to the cluster using `SHOW PROCESSLIST`. If the MySQL server is connected to the cluster, and you have the `PROCESS` privilege, then the first row of the output is as shown here:

```
mysql> SHOW PROCESSLIST \G
***** 1. row *****
  Id: 1
  User: system user
  Host:
  db:
  Command: Daemon
  Time: 1
  State: Waiting for event from ndbcluster
  Info: NULL
```

Important

To participate in a MySQL Cluster, the `mysqld` process must be started with *both* the options `--ndbcluster` and `--ndb-connectstring` (or their equivalents in `my.cnf`). If `mysqld` is started with only the `--ndbcluster` option, or if it is unable to contact the cluster, it is not possible to work with NDB tables, *nor is it possible to create any new tables regardless of storage engine*. The latter restriction is a safety measure intended to prevent the creation of tables having the same names as NDB tables while the SQL node is not connected to the cluster. If you wish to create tables using a different storage engine while the `mysqld` process is not participating in a MySQL Cluster, you must restart the server *without* the `--ndbcluster` option.

16.6.2. ndbd — The Storage Engine Node Process

`ndbd` is the process that is used to handle all the data in tables using the NDB Cluster storage engine. This is the process that empowers a data node to accomplish distributed transaction handling, node recovery, checkpointing to disk, online backup, and related tasks.

In a MySQL Cluster, a set of `ndbd` processes cooperate in handling data. These processes can execute on the same computer (host) or on different computers. The correspondences between data nodes and Cluster hosts is completely configurable.

`ndbd` generates a set of log files which are placed in the directory specified by `DataDir` in the `config.ini` configuration file.

These log files are listed below. `node_id` is the node's unique identifier. Note that `node_id` represents the node's unique identifier. For example, `ndb_2_error.log` is the error log generated by the data node whose node ID is 2.

- `ndb_node_id_error.log` is a file containing records of all crashes which the referenced `ndbd` process has encountered. Each

record in this file contains a brief error string and a reference to a trace file for this crash. A typical entry in this file might appear as shown here:

```
Date/Time: Saturday 30 July 2004 - 00:20:01
Type of error: error
Message: Internal program error (failed ndbrequire)
Fault ID: 2341
Problem data: DbtupFixAlloc.cpp
Object of reference: DBTUP (Line: 173)
ProgramName: NDB Kernel
ProcessID: 14909
TraceFile: ndb_2_trace.log.2
***EOM***
```

Listings of possible `ndbd` exit codes and messages generated when a data node process shuts down prematurely can be found in [ndbd Error Messages](#).

Important

The last entry in the error log file is not necessarily the newest one (nor is it likely to be). Entries in the error log are not listed in chronological order; rather, they correspond to the order of the trace files as determined in the [ndb_node_id_trace.log.next](#) file (see below). Error log entries are thus overwritten in a cyclical and not sequential fashion.

- [ndb_node_id_trace.log.trace_id](#) is a trace file describing exactly what happened just before the error occurred. This information is useful for analysis by the MySQL Cluster development team.
- It is possible to configure the number of these trace files that will be created before old files are overwritten. [trace_id](#) is a number which is incremented for each successive trace file.
- [ndb_node_id_trace.log.next](#) is the file that keeps track of the next trace file number to be assigned.
- [ndb_node_id_out.log](#) is a file containing any data output by the `ndbd` process. This file is created only if `ndbd` is started as a daemon, which is the default behavior.
- [ndb_node_id.pid](#) is a file containing the process ID of the `ndbd` process when started as a daemon. It also functions as a lock file to avoid the starting of nodes with the same identifier.
- [ndb_node_id_signal.log](#) is a file used only in debug versions of `ndbd`, where it is possible to trace all incoming, outgoing, and internal messages with their data in the `ndbd` process.

It is recommended not to use a directory mounted through NFS because in some environments this can cause problems whereby the lock on the `.pid` file remains in effect even after the process has terminated.

To start `ndbd`, it may also be necessary to specify the hostname of the management server and the port on which it is listening. Optionally, one may also specify the node ID that the process is to use.

```
shell> ndbd --connect-string="nodeid=2;host=ndb_mgmd.mysql.com:1186"
```

See [Section 16.4.4.2, “The Cluster Connectstring”](#), for additional information about this issue. [Section 16.6.5, “Command Options for MySQL Cluster Processes”](#), describes other options for `ndbd`.

When `ndbd` starts, it actually initiates two processes. The first of these is called the “angel process”; its only job is to discover when the execution process has been completed, and then to restart the `ndbd` process if it is configured to do so. Thus, if you attempt to kill `ndbd` via the Unix `kill` command, it is necessary to kill both processes, beginning with the angel process. The preferred method of terminating an `ndbd` process is to use the management client and stop the process from there.

The execution process uses one thread for reading, writing, and scanning data, as well as all other activities. This thread is implemented asynchronously so that it can easily handle thousands of concurrent activities. In addition, a watch-dog thread supervises the execution thread to make sure that it does not hang in an endless loop. A pool of threads handles file I/O, with each thread able to handle one open file. Threads can also be used for transporter connections by the transporters in the `ndbd` process. In a multi-processor system performing a large number of operations (including updates), the `ndbd` process can consume up to 2 CPUs if permitted to do so.

For a machine with many CPUs it is possible to use several `ndbd` processes which belong to different node groups; however, such a configuration is still considered experimental and is not supported for MySQL 5.1 in a production setting. See [Section 16.13, “Known](#)

Limitations of MySQL Cluster”.

16.6.3. **ndb_mgmd** — The Management Server Process

The management server is the process that reads the cluster configuration file and distributes this information to all nodes in the cluster that request it. It also maintains a log of cluster activities. Management clients can connect to the management server and check the cluster's status.

It is not strictly necessary to specify a connectstring when starting the management server. However, if you are using more than one management server, a connectstring should be provided and each node in the cluster should specify its node ID explicitly.

See [Section 16.4.4.2, “The Cluster Connectstring”](#), for information about using connectstrings. [Section 16.6.5, “Command Options for MySQL Cluster Processes”](#), describes other options for **ndb_mgmd**.

The following files are created or used by **ndb_mgmd** in its starting directory, and are placed in the **DataDir** as specified in the **config.ini** configuration file. In the list that follows, *node_id* is the unique node identifier.

- **config.ini** is the configuration file for the cluster as a whole. This file is created by the user and read by the management server. [Section 16.4, “MySQL Cluster Configuration”](#), discusses how to set up this file.

- **ndb_node_id_cluster.log** is the cluster events log file. Examples of such events include checkpoint startup and completion, node startup events, node failures, and levels of memory usage. A complete listing of cluster events with descriptions may be found in [Section 16.7, “Management of MySQL Cluster”](#).

When the size of the cluster log reaches one million bytes, the file is renamed to **ndb_node_id_cluster.log.seq_id**, where *seq_id* is the sequence number of the cluster log file. (For example: If files with the sequence numbers 1, 2, and 3 already exist, the next log file is named using the number 4.)

- **ndb_node_id_out.log** is the file used for **stdout** and **stderr** when running the management server as a daemon.
- **ndb_node_id.pid** is the process ID file used when running the management server as a daemon.

16.6.4. **ndb_mgm** — The Management Client Process

The **ndb_mgm** management client process is actually not needed to run the cluster. Its value lies in providing a set of commands for checking the cluster's status, starting backups, and performing other administrative functions. The management client accesses the management server using a C API. Advanced users can also employ this API for programming dedicated management processes to perform tasks similar to those performed by **ndb_mgm**.

To start the management client, it is necessary to supply the hostname and port number of the management server:

```
shell> ndb_mgm [host_name [port_num]]
```

For example:

```
shell> ndb_mgm ndb_mgmd.mysql.com 1186
```

The default hostname and port number are **localhost** and 1186, respectively.

Additional information about using **ndb_mgm** can be found in [Section 16.6.5.4, “Command Options for ndb_mgm”](#), and [Section 16.7.2, “Commands in the MySQL Cluster Management Client”](#).

16.6.5. Command Options for MySQL Cluster Processes

All MySQL Cluster executables (except for **mysqld**) take the options described in this section. Users of earlier MySQL Cluster versions should note that some of these options have been changed to make them consistent with one another as well as with **mysqld**. You can use the **--help** option with any MySQL Cluster executable to view a list of the options which it supports.

The following options are common to all MySQL Cluster executables:

-

`--help --usage, -?`

Prints a short list with descriptions of the available command options.

- `--connect-string=connect_string, -c connect_string`

`connect_string` sets the connectstring to the management server as a command option.

```
shell> ndbd --connect-string="nodeid=2;host=ndb_mgmd.mysql.com:1186"
```

- `--debug[=options]`

This option can be used only for versions compiled with debugging enabled. It is used to enable output from debug calls in the same manner as for the `mysqld` process.

- `--execute=command, -e command`

Can be used to send a command to a Cluster executable from the system shell. For example, either of the following:

```
shell> ndb_mgm -e "SHOW"
```

or

```
shell> ndb_mgm --execute="SHOW"
```

is equivalent to

```
ndb_mgm> SHOW
```

This is analogous to how the `--execute` or `-e` option works with the `mysql` command-line client. See [Section 4.3.1, “Using Options on the Command Line”](#).

- `--version, -V`

Prints the MySQL Cluster version number of the executable. The version number is relevant because not all versions can be used together, and the MySQL Cluster startup process verifies that the versions of the binaries being used can co-exist in the same cluster. This is also important when performing an online (rolling) software upgrade or downgrade of MySQL Cluster. (See [Section 16.5.1, “Performing a Rolling Restart of the Cluster”](#)).

The next few sections describe options specific to individual [NDB](#) programs.

16.6.5.1. MySQL Cluster-Related Command Options for `mysqld`

- `--ndb-connectstring=connect_string`

When using the [NDB Cluster](#) storage engine, this option specifies the management server that distributes cluster configuration data.

- `--ndbcluster`

The [NDB Cluster](#) storage engine is necessary for using MySQL Cluster. If a `mysqld` binary includes support for the [NDB Cluster](#) storage engine, the engine is disabled by default. Use the `--ndbcluster` option to enable it. Use `--skip-ndbcluster` to explicitly disable the engine.

16.6.5.2. Command Options for `ndbd`

For options common to all `NDB` programs, see [Section 16.6.5, “Command Options for MySQL Cluster Processes”](#).

- `--bind-address`

Causes `ndbd` to bind to a specific network interface. This option has no default value.

This option was added in MySQL 5.1.12.

- `--daemon, -d`

Instructs `ndbd` to execute as a daemon process. This is the default behavior. `--nodaemon` can be used to prevent the process from running as a daemon.

- `--initial`

Instructs `ndbd` to perform an initial start. An initial start erases any files created for recovery purposes by earlier instances of `ndbd`. It also re-creates recovery log files. Note that on some operating systems this process can take a substantial amount of time.

An `--initial` start is to be used *only* when starting the `ndbd` process under very special circumstances; this is because this option causes all files to be removed from the Cluster filesystem and all redo log files to be re-created. These circumstances are listed here:

- When performing a software upgrade which has changed the contents of any files.
- When restarting the node with a new version of `ndbd`.
- As a measure of last resort when for some reason the node restart or system restart repeatedly fails. In this case, be aware that this node can no longer be used to restore data due to the destruction of the data files.

Important

This option does *not* affect either of the following:

- Backup files that have already been created by the affected node
- Cluster Disk Data files (see [Section 16.11, “MySQL Cluster Disk Data Tables”](#)).

It is permissible to use this option when starting the cluster for the very first time (that is, before any data node files have been created); however, it is *not* necessary to do so.

- `--initial-start`

This option is used when performing a partial initial start of the cluster. Each node should be started with this option, as well as `--nowait-nodes`.

For example, suppose you have a 4-node cluster whose data nodes have the IDs 2, 3, 4, and 5, and you wish to perform a partial initial start using only nodes 2, 4, and 5 — that is, omitting node 3:

```
ndbd --ndbd-nodeid=2 --nowait-nodes=3 --initial-start
ndbd --ndbd-nodeid=4 --nowait-nodes=3 --initial-start
ndbd --ndbd-nodeid=5 --nowait-nodes=3 --initial-start
```

This option was added in MySQL 5.1.11.

Important

Prior to MySQL 5.1.19, it was not possible to perform DDL operations involving Disk Data tables on a partially started cluster. (See [Bug#24631](#).)

- `--nowait-nodes=node_id_1[, node_id_2[, ...]]`

This option takes a list of data nodes which for which the cluster will not wait for before starting.

This can be used to start the cluster in a partitioned state. For example, to start the cluster with only half of the data nodes (nodes 2, 3, 4, and 5) running in a 4-node cluster, you can start each `ndbd` process with `--nowait-nodes=3,5`. In this case, the cluster starts as soon as nodes 2 and 4 connect, and does *not* wait `StartPartitionedTimeout` milliseconds for nodes 3 and 5 to connect as it would otherwise.

If you wanted to start up the same cluster as in the previous example without one `ndbd` — say, for example, that the host machine for node 3 has suffered a hardware failure — then start nodes 2, 4, and 5 with `--nowait-nodes=3`. Then the cluster will start as soon as nodes 2, 4, and 5 connect and will not wait for node 3 to start.

This option was added in MySQL 5.1.9.

- `--nodaemon`
Instructs `ndbd` not to start as a daemon process. This is useful when `ndbd` is being debugged and you want output to be redirected to the screen.
- `--nostart, -n`
Instructs `ndbd` not to start automatically. When this option is used, `ndbd` connects to the management server, obtains configuration data from it, and initializes communication objects. However, it does not actually start the execution engine until specifically requested to do so by the management server. This can be accomplished by issuing the proper `START` command in the management client (see Section 16.7.2, “Commands in the MySQL Cluster Management Client”).

16.6.5.3. Command Options for `ndb_mgmd`

For options common to NDB programs, see Section 16.6.5, “Command Options for MySQL Cluster Processes”.

- **MySQL Cluster 5.1 Carrier Grade Edition**
The following information applies to users of MySQL Cluster 5.1 Carrier Grade Edition only. For more information about MySQL Cluster 5.1 Carrier Grade Edition, see Section 16.2, “MySQL Cluster 5.1 Carrier Grade Edition”.

`--bind-address=host[:port]`
When specified, this option limits management server connections by management clients to clients at the specified hostname or IP address (and possibly port, if this is also specified). In such cases, a management client attempting to connect to the management server from any other address fails with the error `UNABLE TO SETUP PORT: HOST:PORT!`
If the `port` is not specified, the management client attempts to use port 1186.
This option was added in MySQL 5.1.19-ndb-6.2.5 and MySQL 5.1.22-ndb-6.3.2. It is not available in MySQL Cluster 5.1 Carrier Grade Edition ndb-6.1.x or mainline MySQL 5.1 releases.

The following information applies to all MySQL Cluster users.

`--config-file=filename, -f filename`
Instructs the management server as to which file it should use for its configuration file. This option must be specified. The filename defaults to `config.ini`.

Note
This option also can be given as `-c file_name`, but this shortcut is obsolete and should *not* be used in new installations.
- `--daemon, -d`

Instructs `ndb_mgmd` to start as a daemon process. This is the default behavior.

- `--nodaemon`

Instructs `ndb_mgmd` not to start as a daemon process.

16.6.5.4. Command Options for `ndb_mgm`

For options common to NDB programs, see [Section 16.6.5, “Command Options for MySQL Cluster Processes”](#).

- `--try-reconnect=number`

If the connection to the management server is broken, the node tries to reconnect to it every 5 seconds until it succeeds. By using this option, it is possible to limit the number of attempts to *number* before giving up and reporting an error instead.

16.7. Management of MySQL Cluster

Managing a MySQL Cluster involves a number of tasks, the first of which is to configure and start MySQL Cluster. This is covered in [Section 16.4, “MySQL Cluster Configuration”](#), and [Section 16.6, “Process Management in MySQL Cluster”](#).

The following sections cover the management of a running MySQL Cluster.

There are essentially two methods of actively managing a running MySQL Cluster. The first of these is through the use of commands entered into the management client whereby cluster status can be checked, log levels changed, backups started and stopped, and nodes stopped and started. The second method involves studying the contents of the cluster log `ndb_node_id_cluster.log`; this is usually found in the management server's `DataDir` directory, but this location can be overridden using the `LogDestination` option — see [Section 16.4.4.4, “Defining the Management Server”](#), for details. (Recall that *node_id* represents the unique identifier of the node whose activity is being logged.) The cluster log contains event reports generated by `ndbd`. It is also possible to send cluster log entries to a Unix system log.

In addition, some aspects of the cluster's operation can be monitored from an SQL node using the `SHOW ENGINE NDB STATUS` statement. See [Section 12.5.4.13, “SHOW ENGINE Syntax”](#), for more information.

16.7.1. Summary of MySQL Cluster Start Phases

This section provides a simplified outline of the steps involved when MySQL Cluster data nodes are started. More complete information can be found in [MySQL Cluster Start Phases](#).

These phases are the same as those reported in the output from the `node_id STATUS` command in the management client. (See [Section 16.7.2, “Commands in the MySQL Cluster Management Client”](#), for more information about this command.)

Start types. There are several different startup types and modes, as shown here:

- **Initial Start.** The cluster starts with a clean filesystem on all data nodes. This occurs either when the cluster started for the very first time, or when all data nodes are restarted using the `--initial` option.

Note

Disk Data files are not removed when restarting a node using `--initial`.

- **System Restart.** The cluster starts and reads data stored in the data nodes. This occurs when the cluster has been shut down after having been in use, when it is desired for the cluster to resume operations from the point where it left off.
- **Node Restart.** This is the online restart of a cluster node while the cluster itself is running.
- **Initial Node Restart.** This is the same as a node restart, except that the node is reinitialized and started with a clean filesystem.

Setup and initialization (Phase -1). Prior to startup, each data node (`ndbd` process) must be initialized. Initialization consists of the following steps:

1. Obtain a node ID
2. Fetch configuration data
3. Allocate ports to be used for inter-node communications
4. Allocate memory according to settings obtained from the configuration file

When a data node or SQL node first connects to the management node, it reserves a cluster node ID. To make sure that no other node allocates the same node ID, this ID is retained until the node has managed to connect to the cluster and at least one `ndbd` reports that this node is connected. This retention of the node ID is guarded by the connection between the node in question and `ndb_mgmd`.

Normally, in the event of a problem with the node, the node disconnects from the management server, the socket used for the connection is closed, and the reserved node ID is freed. However, if a node is disconnected abruptly — for example, due to a hardware failure in one of the cluster hosts, or because of network issues — the normal closing of the socket by the operating system may not take place. In this case, the node ID continues to be reserved and not released until a TCP timeout occurs 10 or so minutes later.

To take care of this problem, you can use `PURGE STALE SESSIONS`. Running this statement forces all reserved node IDs to be checked; any that are not being used by nodes actually connected to the cluster are then freed.

Beginning with MySQL 5.1.11, timeout handling of node ID assignments is implemented. This performs the ID usage checks automatically after approximately 20 seconds, so that `PURGE STALE SESSIONS` should no longer be necessary in a normal Cluster start.

After each data node has been initialized, the cluster startup process can proceed. The stages which the cluster goes through during this process are listed here:

- **Phase 0.** The `NDBFS` and `NDBCNTR` blocks start (see [NDB Kernel Blocks](#)). The cluster filesystem is cleared, if the cluster was started with the `--initial` option.
- **Phase 1.** In this stage, all remaining `NDB` kernel blocks are started. Cluster connections are set up, inter-block communications are established, and Cluster heartbeats are started. In the case of a node restart, API node connections are also checked.

Note

When one or more nodes hang in Phase 1 while the remaining node or nodes hang in Phase 2, this often indicates network problems. One possible cause of such issues is one or more cluster hosts having multiple network interfaces. Another common source of problems causing this condition is the blocking of TCP/IP ports needed for communications between cluster nodes. In the latter case, this is often due to a misconfigured firewall.

- **Phase 2.** The `NDBCNTR` kernel block checks the states of all existing nodes. The master node is chosen, and the cluster schema file is initialized.
- **Phase 3.** The `DBLQH` and `DBTC` kernel blocks set up communications between them. The startup type is determined; if this is a restart, the `DBDIH` block obtains permission to perform the restart.
- **Phase 4.** For an initial start or initial node restart, the redo log files are created. The number of these files is equal to `NoOfFragmentLogFiles`.

For a system restart:

- Read schema or schemas.
- Read data from the local checkpoint.
- Apply all redo information until the latest restorable global checkpoint has been reached.

For a node restart, find the tail of the redo log.

- **Phase 5.** Most of the database-related portion of a data node start is performed during this phase. For an initial start or system restart, a local checkpoint is executed, followed by a global checkpoint. Periodic checks of memory usage begin during this phase, and any required node takeovers are performed.
- **Phase 6.** In this phase, node groups are defined and set up.

- **Phase 7.** The arbitrator node is selected and begins to function. The next backup ID is set, as is the backup disk write speed. Nodes reaching this start phase are marked as **Started**. It is now possible for API nodes (including SQL nodes) to connect to the cluster.
- **Phase 8.** If this is a system restart, all indexes are rebuilt (by **DBDIIH**).
- **Phase 9.** The node internal startup variables are reset.
- **Phase 100 (OBSOLETE).** Formerly, it was at this point during a node restart or initial node restart that API nodes could connect to the node and begin to receive events. Currently, this phase is empty.
- **Phase 101.** At this point in a node restart or initial node restart, event delivery is handed over to the node joining the cluster. The newly-joined node takes over responsibility for delivering its primary data to subscribers. This phase is also referred to as **SUMA handover phase**.

After this process is completed for an initial start or system restart, transaction handling is enabled. For a node restart or initial node restart, completion of the startup process means that the node may now act as a transaction coordinator.

16.7.2. Commands in the MySQL Cluster Management Client

In addition to the central configuration file, a cluster may also be controlled through a command-line interface available through the management client **ndb_mgm**. This is the primary administrative interface to a running cluster.

Commands for the event logs are given in [Section 16.7.3, “Event Reports Generated in MySQL Cluster”](#); commands for creating backups and restoring from backup are provided in [Section 16.8, “On-line Backup of MySQL Cluster”](#).

The management client has the following basic commands. In the listing that follows, *node_id* denotes either a database node ID or the keyword **ALL**, which indicates that the command should be applied to all of the cluster's data nodes.

- **HELP**
Displays information on all available commands.

- **SHOW**
Displays information on the cluster's status.

Note

In a cluster where multiple management nodes are in use, this command displays information only for data nodes that are actually connected to the current management server.

- **node_id START**
Brings online the data node identified by *node_id* (or all data nodes).
ALL START works on all data nodes only, and does not affect management nodes.

Important

To use this command to bring a data node online, the data node must have been started using **ndbd --nostart** or **ndbd -n**.

- **node_id STOP**
Stops the data or management node identified by *node_id*. Note that **ALL STOP** works to stop all data nodes only, and does not affect management nodes.
A node affected by this command disconnects from the cluster, and its associated **ndbd** or **ndb_mgmd** process terminates.

- `node_id RESTART [-n] [-i] [-a]`

Restarts the data node identified by `node_id` (or all data nodes).

Using the `-i` option with `RESTART` causes the data node to perform an initial restart; that is, the node's filesystem is deleted and re-created. The effect is the same as that obtained from stopping the data node process and then starting it again using `ndbd -initial` from the system shell. Note that backup files and Disk Data files are not removed when this option is used.

Using the `-n` option causes the data node process to be restarted, but the data node is not actually brought online until the appropriate `START` command is issued. The effect of this option is the same as that obtained from stopping the data node and then starting it again using `ndbd --nostart` or `ndbd -n` from the system shell.

Using the `-a` causes all current transactions relying on this node to be aborted. No GCP check is done when the node rejoins the cluster.

- `node_id STATUS`

Displays status information for the data node identified by `node_id` (or for all data nodes).

MySQL Cluster 5.1 Carrier Grade Edition

The following information applies to users of MySQL Cluster 5.1 Carrier Grade Edition only. For more information about MySQL Cluster 5.1 Carrier Grade Edition, see Section 16.2, "MySQL Cluster 5.1 Carrier Grade Edition".

`node_id REPORT report-type`

Displays a report of type `report-type` for the data node identified by `node_id`, or for all data nodes using `ALL`.

Currently, the only accepted value for `report-type` is `BackupStatus`, which provides a status report on a cluster backup in progress.

The `REPORT` command was introduced in MySQL 5.1.8-ndb-6.2.3.

The following information applies to all MySQL Cluster users.

- `ENTER SINGLE USER MODE node_id`

Enters single user mode, whereby only the MySQL server identified by the node ID `node_id` is allowed to access the database.

Important

It is not possible in MySQL 5.1 for data nodes to join the cluster while it is running in single user mode. (See [Bug#20395](#) for more information.)

- `EXIT SINGLE USER MODE`

Exits single user mode, allowing all SQL nodes (that is, all running `mysqld` processes) to access the database.

- `QUIT, EXIT`

Terminates the management client.

This command does not affect any nodes connected to the cluster.

- `SHUTDOWN`

Shuts down all cluster data nodes and management nodes. To exit the management client after this has been done, use `EXIT` or `QUIT`.

This command does *not* shut down any SQL nodes or API nodes that are connected to the cluster.

16.7.3. Event Reports Generated in MySQL Cluster

In this section, we discuss the types of event logs provided by MySQL Cluster, and the types of events that are logged.

MySQL Cluster provides two types of event log:

- The *cluster log*, which includes events generated by all cluster nodes. The cluster log is the log recommended for most uses because it provides logging information for an entire cluster in a single location.

By default, the cluster log is saved to a file named `ndb_node_id_cluster.log`, (where *node_id* is the node ID of the management server) in the same directory where the `ndb_mgm` binary resides.

Cluster logging information can also be sent to `stdout` or a `syslog` facility in addition to or instead of being saved to a file, as determined by the values set for the `DataDir` and `LogDestination` configuration parameters. See [Section 16.4.4.4, “Defining the Management Server”](#), for more information about these parameters.

- *Node logs* are local to each node.

Output generated by node event logging is written to the file `ndb_node_id_out.log` (where *node_id* is the node's node ID) in the node's `DataDir`. Node event logs are generated for both management nodes and data nodes.

Node logs are intended to be used only during application development, or for debugging application code.

Both types of event logs can be set to log different subsets of events.

Each reportable event can be distinguished according to three different criteria:

- *Category*: This can be any one of the following values: `STARTUP`, `SHUTDOWN`, `STATISTICS`, `CHECKPOINT`, `NODERESTART`, `CONNECTION`, `ERROR`, or `INFO`.
- *Priority*: This is represented by one of the numbers from 1 to 15 inclusive, where 1 indicates “most important” and 15 “least important.”
- *Severity Level*: This can be any one of the following values: `ALERT`, `CRITICAL`, `ERROR`, `WARNING`, `INFO`, or `DEBUG`.

Both the cluster log and the node log can be filtered on these properties.

The format used in the cluster log is as shown here:

```
2007-01-26 19:35:55 [MgmSrvr] INFO      -- Node 1: Data usage is 2%(60 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO      -- Node 1: Index usage is 1%(24 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO      -- Node 1: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:35:55 [MgmSrvr] INFO      -- Node 2: Data usage is 2%(76 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO      -- Node 2: Index usage is 1%(24 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO      -- Node 2: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:35:55 [MgmSrvr] INFO      -- Node 3: Data usage is 2%(58 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO      -- Node 3: Index usage is 1%(25 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO      -- Node 3: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:35:55 [MgmSrvr] INFO      -- Node 4: Data usage is 2%(74 32K pages of total 2560)
2007-01-26 19:35:55 [MgmSrvr] INFO      -- Node 4: Index usage is 1%(25 8K pages of total 2336)
2007-01-26 19:35:55 [MgmSrvr] INFO      -- Node 4: Resource 0 min: 0 max: 639 curr: 0
2007-01-26 19:39:42 [MgmSrvr] INFO      -- Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO      -- Node 1: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO      -- Node 1: Node 9: API version 5.1.15
2007-01-26 19:39:42 [MgmSrvr] INFO      -- Node 2: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO      -- Node 2: Node 9: API version 5.1.15
2007-01-26 19:39:42 [MgmSrvr] INFO      -- Node 3: Node 9 Connected
2007-01-26 19:39:42 [MgmSrvr] INFO      -- Node 3: Node 9: API version 5.1.15
2007-01-26 19:39:42 [MgmSrvr] INFO      -- Node 4: Node 9: API version 5.1.15
2007-01-26 19:59:22 [MgmSrvr] ALERT     -- Node 2: Node 7 Disconnected
2007-01-26 19:59:22 [MgmSrvr] ALERT     -- Node 2: Node 7 Disconnected
```

Each line in the cluster log contains the following information:

- A timestamp in `YYYY-MM-DD HH:MM:SS` format.
- The type of node which is performing the logging. In the cluster log, this is always `[MgmSrvr]`.
- The severity of the event.
- The ID of the node reporting the event.
- A description of the event. The most common types of events to appear in the log are connections and disconnections between different nodes in the cluster, and when checkpoints occur. In some cases, the description may contain status information.

16.7.3.1. Logging Management Commands

The following management commands are related to the cluster log:

- `CLUSTERLOG ON`
Turns the cluster log on.
- `CLUSTERLOG OFF`
Turns the cluster log off.
- `CLUSTERLOG INFO`
Provides information about cluster log settings.
- `node_id CLUSTERLOG category=threshold`
Logs *category* events with priority less than or equal to *threshold* in the cluster log.
- `CLUSTERLOG FILTER severity_level`
Toggles cluster logging of events of the specified *severity_level*.

The following table describes the default setting (for all data nodes) of the cluster log category threshold. If an event has a priority with a value lower than or equal to the priority threshold, it is reported in the cluster log.

Note that events are reported per data node, and that the threshold can be set to different values on different nodes.

Category	Default threshold (All data nodes)
STARTUP	7
SHUTDOWN	7
STATISTICS	7
CHECKPOINT	7
NODERESTART	7
CONNECTION	7
ERROR	15
INFO	7

The `STATISTICS` category can provide a great deal of useful data. See [Section 16.7.3.3, “Using CLUSTERLOG STATISTICS”](#), for more information.

Thresholds are used to filter events within each category. For example, a `STARTUP` event with a priority of 3 is not logged unless the threshold for `STARTUP` is changed to 3 or lower. Only events with priority 3 or lower are sent if the threshold is 3.

The following table shows the event severity levels.

Note

These correspond to Unix `syslog` levels, except for `LOG_EMERG` and `LOG_NOTICE`, which are not used or mapped.

1	ALERT	A condition that should be corrected immediately, such as a corrupted system database
2	CRITICAL	Critical conditions, such as device errors or insufficient resources
3	ERROR	Conditions that should be corrected, such as configuration errors
4	WARNING	Conditions that are not errors, but that might require special handling
5	INFO	Informational messages
6	DEBUG	Debugging messages used for NDB Cluster development

Event severity levels can be turned on or off (using `CLUSTERLOG FILTER` — see above). If a severity level is turned on, then all events with a priority less than or equal to the category thresholds are logged. If the severity level is turned off then no events belonging to that severity level are logged.

16.7.3.2. Log Events

An event report reported in the event logs has the following format:

```
datetime [string] severity -- message
```

For example:

```
09:19:30 2005-07-24 [NDB] INFO -- Node 4 Start phase 4 completed
```

This section discusses all reportable events, ordered by category and severity level within each category.

In the event descriptions, GCP and LCP mean “Global Checkpoint” and “Local Checkpoint”, respectively.

CONNECTION Events

These events are associated with connections between Cluster nodes.

Event	Priority	Severity Level	Description
data nodes connected	8	INFO	Data nodes connected
data nodes disconnected	8	INFO	Data nodes disconnected
Communication closed	8	INFO	SQL node or data node connection closed
Communication opened	8	INFO	SQL node or data node connection opened

CHECKPOINT Events

The logging messages shown here are associated with checkpoints.

Event	Priority	Severity Level	Description
LCP stopped in calc keep GCI	0	ALERT	LCP stopped
Local checkpoint fragment completed	11	INFO	LCP on a fragment has been completed
Global checkpoint completed	10	INFO	GCP finished
Global checkpoint started	9	INFO	Start of GCP: REDO log is written to disk
Local checkpoint completed	8	INFO	LCP completed normally
Local checkpoint started	7	INFO	Start of LCP: data written to disk

STARTUP Events

The following events are generated in response to the startup of a node or of the cluster and of its success or failure. They also provide information relating to the progress of the startup process, including information concerning logging activities.

Event	Priority	Severity Level	Description
Internal start signal received STORRY	15	INFO	Blocks received after completion of restart
New REDO log started	10	INFO	GCI keep <i>X</i> , newest restorable GCI <i>Y</i>
New log started	10	INFO	Log part <i>X</i> , start MB <i>Y</i> , stop MB <i>Z</i>
Node has been refused for inclusion in the cluster	8	INFO	Node cannot be included in cluster due to misconfiguration, inability to establish communication, or other problem
data node neighbors	8	INFO	Shows neighboring data nodes
data node start phase <i>X</i> completed	4	INFO	A data node start phase has been completed
Node has been successfully included into the cluster	3	INFO	Displays the node, managing node, and dynamic ID
data node start phases initiated	1	INFO	NDB Cluster nodes starting
data node all start phases completed	1	INFO	NDB Cluster nodes started
data node shutdown initiated	1	INFO	Shutdown of data node has commenced
data node shutdown aborted	1	INFO	Unable to shut down data node normally

NODERESTART Events

The following events are generated when restarting a node and relate to the success or failure of the node restart process.

Event	Priority	Severity Level	Description
Node failure phase completed	8	ALERT	Reports completion of node failure phases
Node has failed, node state was <i>X</i>	8	ALERT	Reports that a node has failed
Report arbitrator results	2	ALERT	There are eight different possible results for arbitration attempts: - Arbitration check failed — less than 1/2 nodes left - Arbitration check succeeded — node group majority - Arbitration check failed — missing node group - Network partitioning — arbitration required - Arbitration succeeded — affirmative response from node <i>X</i> - Arbitration failed - negative response from node <i>X</i> - Network partitioning - no arbitrator available - Network partitioning - no arbitrator configured
Completed copying a fragment	10	INFO	
Completed copying of dictionary information	8	INFO	
Completed copying distribution information	8	INFO	
Starting to copy fragments	8	INFO	
Completed copying all fragments	8	INFO	

GCP takeover started	7	INFO	
GCP takeover completed	7	INFO	
LCP takeover started	7	INFO	
LCP takeover completed (state = <i>X</i>)	7	INFO	
Report whether an arbitrator is found or not	6	INFO	There are seven different possible outcomes when seeking an arbitrator: • Management server restarts arbitration thread [state=<i>X</i>] • Prepare arbitrator node <i>X</i> [ticket=<i>Y</i>] • Receive arbitrator node <i>X</i> [ticket=<i>Y</i>] • Started arbitrator node <i>X</i> [ticket=<i>Y</i>] • Lost arbitrator node <i>X</i> - process failure [state=<i>Y</i>] • Lost arbitrator node <i>X</i> - process exit [state=<i>Y</i>] • Lost arbitrator node <i>X</i> <error msg> [state=<i>Y</i>]

STATISTICS Events

The following events are of a statistical nature. They provide information such as numbers of transactions and other operations, amount of data sent or received by individual nodes, and memory usage.

Event	Priority	Severity Level	Description
Report job scheduling statistics	9	INFO	Mean internal job scheduling statistics
Sent number of bytes	9	INFO	Mean number of bytes sent to node <i>X</i>
Received # of bytes	9	INFO	Mean number of bytes received from node <i>X</i>
Report transaction statistics	8	INFO	Numbers of: transactions, commits, reads, simple reads, writes, concurrent operations, attribute information, and aborts
Report operations	8	INFO	Number of operations
Report table create	7	INFO	
Memory usage	5	INFO	Data and index memory usage (80%, 90%, and 100%)

ERROR Events

These events relate to Cluster errors and warnings. The presence of one or more of these generally indicates that a major malfunction or failure has occurred.

Event	Priority	Severity	Description
Dead due to missed heartbeat	8	ALERT	Node <i>X</i> declared “dead” due to missed heartbeat
Transporter errors	2	ERROR	
Transporter warnings	8	WARNING	
Missed heartbeats	8	WARNING	Node <i>X</i> missed heartbeat # <i>Y</i>
General warning events	2	WARNING	

INFO Events

These events provide general information about the state of the cluster and activities associated with Cluster maintenance, such as logging and heartbeat transmission.

Event	Priority	Severity	Description
Sent heartbeat	12	INFO	Heartbeat sent to node <i>X</i>
Create log bytes	11	INFO	Log part, log file, MB
General information events	2	INFO	

16.7.3.3. Using **CLUSTERLOG STATISTICS**

The **NDB** management client's **CLUSTERLOG STATISTICS** command can provide a number of useful statistics in its output. The following statistics are reported by the transaction coordinator:

Statistic	Description (Number of...)
Trans. Count	Transactions attempted with this node as coordinator
Commit Count	Transactions committed with this node as coordinator
Read Count	Primary key reads (all)
Simple Read Count	Primary key reads reading the latest committed value
Write Count	Primary key writes (includes all INSERT , UPDATE , and DELETE operations)
AttrInfoCount	Data words used to describe all reads and writes received
Concurrent Operations	All concurrent operations ongoing at the moment the report is taken
Abort Count	Transactions with this node as coordinator that were aborted
Scans	Scans (all)
Range Scans	Index scans

The **ndbd** process has a scheduler that runs in an infinite loop. During each loop scheduler performs the following tasks:

1. Read any incoming messages from sockets into a job buffer.
2. Check whether there are any timed messages to be executed; if so, put these into the job buffer as well.
3. Execute (in a loop) any messages in the job buffer.
4. Send any distributed messages that were generated by executing the messages in the job buffer.
5. Wait for any new incoming messages.

The number of loops executed in the third step is reported as the **Mean Loop Counter**. This statistic increases in size as the utilisation of the TCP/IP buffer improves. You can use this to monitor performance as you add new processes to the cluster.

The **Mean send size** and **Mean receive size** statistics allow you to gauge the efficiency of writes and reads (respectively) between nodes. These values are given in bytes. Higher values mean a lower cost per byte sent or received; the maximum is 64k.

To cause all cluster log statistics to be logged, you can use the following command in the **NDB** management client:

```
ndb_mgm> ALL CLUSTERLOG STATISTICS=15
```

Note

Setting the threshold for **STATISTICS** to 15 causes the cluster log to become very verbose, and to grow quite rapidly in size, in direct proportion to the number of cluster nodes and the amount of activity on the cluster.

16.7.4. Single User Mode

Single user mode allows the database administrator to restrict access to the database system to a single API node, such as a MySQL server (SQL node) or an instance of `ndb_restore`. When entering single user mode, connections to all other API nodes are closed gracefully and all running transactions are aborted. No new transactions are permitted to start.

Once the cluster has entered single user mode, only the designated API node is granted access to the database.

You can use the `ALL STATUS` command to see when the cluster has entered single user mode.

Example:

```
ndb_mgm> ENTER SINGLE USER MODE 5
```

After this command has executed and the cluster has entered single user mode, the API node whose node ID is `5` becomes the cluster's only permitted user.

The node specified in the preceding command must be an API node; attempting to specify any other type of node will be rejected.

Note

When the preceding command is invoked, all transactions running on the designated node are aborted, the connection is closed, and the server must be restarted.

The command `EXIT SINGLE USER MODE` changes the state of the cluster's data nodes from single user mode to normal mode. API nodes — such as MySQL Servers — waiting for a connection (that is, waiting for the cluster to become ready and available), are again permitted to connect. The API node denoted as the single-user node continues to run (if still connected) during and after the state change.

Example:

```
ndb_mgm> EXIT SINGLE USER MODE
```

There are two recommended ways to handle a node failure when running in single user mode:

- Method 1:
 1. Finish all single user mode transactions
 2. Issue the `EXIT SINGLE USER MODE` command
 3. Restart the cluster's data nodes
- Method 2:

Restart database nodes prior to entering single user mode.

16.7.5. Quick Reference: MySQL Cluster SQL Statements

This section discusses several SQL statements that can prove useful in managing and monitoring a MySQL server that is connected to a MySQL Cluster, and in some cases provide information about the cluster itself.

- `SHOW ENGINE NDB STATUS, SHOW ENGINE NDBCLUSTER STATUS`

The output of this statement contains information about the server's connection to the cluster, creation and usage of MySQL Cluster objects, and binary logging for MySQL Cluster replication.

See [Section 12.5.4.13, “SHOW ENGINE Syntax”](#), for a usage example and more detailed information.

- `SHOW ENGINES`

This statement can be used to determine whether or not clustering support is enabled in the MySQL server, and if so, whether it is active.

See [Section 12.5.4.14, “SHOW ENGINES Syntax”](#), for more detailed information.

Note

In MySQL 5.1, this statement no longer supports a [LIKE](#) clause. However, you can use [LIKE](#) to filter queries against the `INFORMATION_SCHEMA.ENGINES`, as discussed in the next item.

- `SELECT * FROM INFORMATION_SCHEMA.ENGINES [WHERE ENGINE LIKE 'NDB%']`

This is the equivalent of `SHOW ENGINES`, but uses the `ENGINES` table of the `INFORMATION_SCHEMA` database (available beginning with MySQL 5.1.5). Unlike the case with the `SHOW ENGINES` statement, it is possible to filter the results using a [LIKE](#) clause, and to select specific columns to obtain information that may be of use in scripts. For example, the following query shows whether the server was built with `NDB` support and, if so, whether it is enabled:

```
mysql> SELECT SUPPORT FROM INFORMATION_SCHEMA.ENGINES
-> WHERE ENGINE LIKE 'NDB%';
+-----+
| support |
+-----+
| ENABLED |
+-----+
```

See [Section 23.18, “The INFORMATION_SCHEMA ENGINES Table”](#), for more information.

- `SHOW VARIABLES LIKE 'NDB%'`

This statement provides a list of most server system variables relating to the `NDB` storage engine, and their values, as shown here:

```
mysql> SHOW VARIABLES LIKE 'NDB%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| ndb_autoincrement_prefetch_sz | 32 |
| ndb_cache_check_time | 0 |
| ndb_extra_logging | 0 |
| ndb_force_send | ON |
| ndb_index_stat_cache_entries | 32 |
| ndb_index_stat_enable | OFF |
| ndb_index_stat_update_freq | 20 |
| ndb_report_thresh_binlog_epoch_slip | 3 |
| ndb_report_thresh_binlog_mem_usage | 10 |
| ndb_use_copying_alter_table | OFF |
| ndb_use_exact_count | ON |
| ndb_use_transactions | ON |
+-----+-----+
```

See [Section 5.2.3, “System Variables”](#), for more information.

- `SELECT * FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES WHERE VARIABLE_NAME LIKE 'NDB%';`

This statement is the equivalent of the `SHOW` described in the previous item, and provides almost identical output, as shown here:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES
-> WHERE VARIABLE_NAME LIKE 'NDB%';
+-----+-----+
| VARIABLE_NAME | VARIABLE_VALUE |
+-----+-----+
| NDB_AUTOINCREMENT_PREFETCH_SZ | 32 |
| NDB_CACHE_CHECK_TIME | 0 |
| NDB_EXTRA_LOGGING | 0 |
| NDB_FORCE_SEND | ON |
| NDB_INDEX_STAT_CACHE_ENTRIES | 32 |
| NDB_INDEX_STAT_ENABLE | OFF |
| NDB_INDEX_STAT_UPDATE_FREQ | 20 |
| NDB_REPORT_THRESH_BINLOG_EPOCH_SLIP | 3 |
| NDB_REPORT_THRESH_BINLOG_MEM_USAGE | 10 |
| NDB_USE_COPYING_ALTER_TABLE | OFF |
| NDB_USE_EXACT_COUNT | ON |
| NDB_USE_TRANSACTIONS | ON |
+-----+-----+
```

Unlike the case with the `SHOW` statement, it is possible to select individual columns. For example:

```
mysql> SELECT VARIABLE_VALUE
-> FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES
-> WHERE VARIABLE_NAME = 'ndb_force_send';
+-----+
| VARIABLE_VALUE |
+-----+
| ON              |
+-----+
```

See [Section 23.25, “The INFORMATION_SCHEMA GLOBAL_VARIABLES and SESSION_VARIABLES Tables”](#), and [Section 5.2.3, “System Variables”](#), for more information.

- **SHOW STATUS LIKE 'NDB%'**

This statement shows at a glance whether or not the MySQL server is acting as a cluster SQL node, and if so, it provides the MySQL server's cluster node ID, the hostname and port for the cluster management server to which it is connected, and the number of data nodes in the cluster, as shown here:

```
mysql> SHOW STATUS LIKE 'NDB%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_cluster_node_id | 10 |
| Ndb_config_from_host | 192.168.0.103 |
| Ndb_config_from_port | 1186 |
| Ndb_number_of_data_nodes | 4 |
+-----+-----+
```

If the MySQL server was built with clustering support, but it is not connected to a cluster, all rows in the output of this statement contain a zero or an empty string:

```
mysql> SHOW STATUS LIKE 'NDB%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ndb_cluster_node_id | 0 |
| Ndb_config_from_host | 0 |
| Ndb_config_from_port | 0 |
| Ndb_number_of_data_nodes | 0 |
+-----+-----+
```

See also [Section 12.5.4.27, “SHOW STATUS Syntax”](#).

- **SELECT * FROM INFORMATION_SCHEMA.GLOBAL_STATUS WHERE VARIABLE_NAME LIKE 'NDB%';**

Beginning with MySQL 5.1.12, this statement provides similar output to the **SHOW** statement discussed in the previous item. However, unlike the case with **SHOW STATUS**, it is possible using the **SELECT** to extract values in SQL for use in scripts for monitoring and automation purposes.

See [Section 23.24, “The INFORMATION_SCHEMA GLOBAL_STATUS and SESSION_STATUS Tables”](#), for more information.

16.8. On-line Backup of MySQL Cluster

This section describes how to create a backup and how to restore the database from a backup at a later time.

16.8.1. Cluster Backup Concepts

A backup is a snapshot of the database at a given time. The backup consists of three main parts:

- **Metadata.** The names and definitions of all database tables
- **Table records.** The data actually stored in the database tables at the time that the backup was made
- **Transaction log.** A sequential record telling how and when data was stored in the database

Each of these parts is saved on all nodes participating in the backup. During backup, each node saves these three parts into three files on disk:

- `BACKUP-backup_id.node_id.ctl`

A control file containing control information and metadata. Each node saves the same table definitions (for all tables in the cluster) to its own version of this file.

- `BACKUP-backup_id-0.node_id.data`

A data file containing the table records, which are saved on a per-fragment basis. That is, different nodes save different fragments during the backup. The file saved by each node starts with a header that states the tables to which the records belong. Following the list of records there is a footer containing a checksum for all records.

- `BACKUP-backup_id.node_id.log`

A log file containing records of committed transactions. Only transactions on tables stored in the backup are stored in the log. Nodes involved in the backup save different records because different nodes host different database fragments.

In the listing above, *backup_id* stands for the backup identifier and *node_id* is the unique identifier for the node creating the file.

16.8.2. Using The Management Client to Create a Backup

Before starting a backup, make sure that the cluster is properly configured for performing one. (See [Section 16.8.4, “Configuration for Cluster Backup”](#).)

Creating a backup using the management client involves the following steps:

1. Start the management client (`ndb_mgm`).
2. Execute the command `START BACKUP`.
3. The management client responds as shown here:

```
Waiting for completed, this may take several minutes
Node 1: Backup backup_id started from node management_node_id
```

Here, *backup_id* is the unique identifier for this particular backup. (This identifier will also be saved in the cluster log, if it has not been configured otherwise.) *management_node_id* is the node ID of the management to which the management client is connected.

This means that the cluster has received and processed the backup request. It does *not* mean that the backup has been completed.

Note

Backup messages were not recorded in the cluster log in MySQL 5.1.12 or 5.1.13. The logging of backup operations was restored in MySQL 5.1.14 (see [Bug#24544](#)).

4. When the backup is completed, the management client will indicate this as shown here:

```
Node 1: Backup backup_id started from node management_node_id completed
StartGCP: 417599 StopGCP: 417602
#Records: 105957 #LogRecords: 0
Data: 99719356 bytes Log: 0 bytes
```

The values shown for `StartGCP`, `StopGCP`, `#Records`, `#LogRecords`, `Data`, and `Log` will vary according to the specifics of your cluster.

Cluster backups are created by default in the `BACKUP` subdirectory of the `DataDir` on each data node. This can be overridden for one or more data nodes individually, or for all cluster data nodes in the `config.ini` file using the `BackupDataDir` configuration parameter as discussed in [Identifying Data Nodes](#). The backup files created for a backup with a given *backup_id* are stored in a subdirect-

ory named `BACKUP-backup_id` in the backup directory.

To abort a backup that is already in progress:

1. Start the management client.
2. Execute this command:

```
ndb_mgm> ABORT BACKUP backup_id
```

The number *backup_id* is the identifier of the backup that was included in the response of the management client when the backup was started (in the message `Backup backup_id started from node management_node_id`).

3. The management client will acknowledge the abort request with `Abort of backup backup_id ordered`.

Note

At this point, the management client has not yet received a response from the cluster data nodes to this request, and the backup has not yet actually been aborted.

4. After the backup has been aborted, the management client will report this fact in a manner similar to what is shown here:

```
Node 1: Backup 3 started from 5 has been aborted. Error: 1321 - Backup aborted by user request: Permanent error: User
Node 3: Backup 3 started from 5 has been aborted. Error: 1323 - 1323: Permanent error: Internal error
Node 2: Backup 3 started from 5 has been aborted. Error: 1323 - 1323: Permanent error: Internal error
Node 4: Backup 3 started from 5 has been aborted. Error: 1323 - 1323: Permanent error: Internal error
```

In this example, we have shown sample output for a cluster with 4 data nodes, where the sequence number of the backup to be aborted is `3`, and the management node to which the cluster management client is connected has the node ID `5`. The first node to complete its part in aborting the backup reports that the reason for the abort was due to a request by the user. (The remaining nodes report that the backup was aborted due to an unspecified internal error.)

Note

There is no guarantee that the cluster nodes respond to an `ABORT BACKUP` command in any particular order.

The `Backup backup_id started from node management_node_id has been aborted` messages mean that the backup has been terminated and that all files relating to this backup have been removed from the cluster filesystem.

It is also possible to abort a backup in progress from a system shell using this command:

```
shell> ndb_mgm -e "ABORT BACKUP backup_id"
```

Note

If there is no backup with ID *backup_id* running when an `ABORT BACKUP` is issued, the management client makes no response, nor is it indicated in the cluster log that an invalid abort command was sent.

16.8.3. `ndb_restore` — Restore a Cluster Backup

The cluster restoration program is implemented as a separate command-line utility `ndb_restore`, which can normally be found in the MySQL `bin` directory. This program reads the files created as a result of the backup and inserts the stored information into the database.

`ndb_restore` must be executed once for each of the backup files that were created by the `START BACKUP` command used to create the backup (see [Section 16.8.2, “Using The Management Client to Create a Backup”](#)). This is equal to the number of data nodes in the cluster at the time that the backup was created.

Note

Before using `ndb_restore`, it is recommended that the cluster be running in single user mode, unless you are restoring multiple data nodes in parallel. See [Section 16.7.4, “Single User Mode”](#), for more information about single user mode.

Typical options for this utility are shown here:

```
ndb_restore [-c connectstring] -n node_id [-s] [-m] -b backup_id -r [backup_path=]/path/to/backup/files [-e]
```

The `-c` option is used to specify a connectstring which tells `ndb_restore` where to locate the cluster management server. (See [Section 16.4.4.2, “The Cluster Connectstring”](#), for information on connectstrings.) If this option is not used, then `ndb_restore` attempts to connect to a management server on `localhost:1186`. This utility acts as a cluster API node, and so requires a free connection “slot” to connect to the cluster management server. This means that there must be at least one `[API]` or `[MYSQLD]` section that can be used by it in the cluster `config.ini` file. It is a good idea to keep at least one empty `[API]` or `[MYSQLD]` section in `config.ini` that is not being used for a MySQL server or other application for this reason (see [Section 16.4.4.6, “Defining SQL and Other API Nodes”](#)).

You can verify that `ndb_restore` is connected to the cluster by using the `SHOW` command in the `ndb_mgm` management client. You can also accomplish this from a system shell, as shown here:

```
shell> ndb_mgm -e "SHOW"
```

`-n` is used to specify the node ID of the data node on which the backups were taken.

The first time you run the `ndb_restore` restoration program, you also need to restore the metadata. In other words, you must re-create the database tables — this can be done by running it with the `-m` option. Note that the cluster should have an empty database when starting to restore a backup. (In other words, you should start `ndbd` with `--initial` prior to performing the restore. You should also remove manually any Disk Data files present in the data node's `DataDir`.)

MySQL Cluster 5.1 Carrier Grade Edition

The following information does not apply to users of MySQL Cluster 5.1 Carrier Grade Edition. For more information about MySQL Cluster 5.1 Carrier Grade Edition, see [Section 16.2, “MySQL Cluster 5.1 Carrier Grade Edition”](#).

It is possible to restore data without restoring table metadata. Prior to MySQL 5.1.17, `ndb_restore` did not perform any checks of table schemas; if a table was altered between the time the backup was taken and when `ndb_restore` was run, `ndb_restore` would still attempt to restore the data to the altered table.

Beginning with MySQL 5.1.17, the default behavior is for `ndb_restore` is to fail with an error if table data do not match the table schema; this can be overridden using the `--skip-table-check` or `-s` option. If this option is used, then `ndb_restore` attempts to fit data into the existing table schema. *The result of restoring a backup to a table schema that does not match the original is unspecified and is subject to change without notice. (Bug#24363)*

The following information applies to all MySQL Cluster users.

The `-b` option is used to specify the ID or sequence number of the backup, and is the same number shown by the management client in the `Backup backup_id completed` message displayed upon completion of a backup. (See [Section 16.8.2, “Using The Management Client to Create a Backup”](#).)

`-e` adds (or restores) epoch information to the cluster replication status table. This is useful for starting replication on a MySQL Cluster replication slave. When this option is used, the row in the `mysql.ndb_apply_status` having `0` in the `id` column is updated if it already exists; such a row is inserted if it does not already exist. (See [Section 16.10.9, “MySQL Cluster Backups With Replication”](#).)

The path to the backup directory is required, and must include the subdirectory corresponding to the ID backup of the backup to be restored. For example, if the data node's `DataDir` is `/var/lib/mysql-cluster`, then the backup directory is `/var/lib/mysql-cluster/BACKUP`, and the backup files for the backup with the ID 3 can be found in `/var/lib/mysql-cluster/BACKUP/BACKUP-3`. The path may be absolute or relative to the directory in which the `ndb_restore` executable is located, and may be optionally prefixed with `backup_path=`.

Important

When restoring cluster backups, you must be sure to restore all data nodes from backups having the same backup ID. Using files from different backups will at best result in restoring the cluster to an inconsistent state, and may fail altogether.

It is possible to restore a backup to a database with a different configuration than it was created from. For example, suppose that a backup with backup ID `12`, created in a cluster with two database nodes having the node IDs `2` and `3`, is to be restored to a cluster with four nodes. Then `ndb_restore` must be run twice — once for each database node in the cluster where the backup was taken. However, `ndb_restore` cannot always restore backups made from a cluster running one version of MySQL to a cluster running a different MySQL version. See [Section 16.5.2, “Cluster Upgrade and Downgrade Compatibility”](#), for more information.

Note

For more rapid restoration, the data may be restored in parallel, provided that there is a sufficient number of cluster connections available. That is, when restoring to multiple nodes in parallel, you must have an `[API]` or `[MYSQLD]` section in the cluster `config.ini` file available for each concurrent `ndb_restore` process. However, the data files must always be applied before the logs.

Most of the options available for this program are shown in the following table:

Long Form	Short Form	Description	Default Value
<code>--backup-id</code>	<code>-b</code>	Backup sequence ID	<code>0</code>
<code>--backup_path</code>	<i>None</i>	Path to backup files	<code>./</code>
<code>--character-sets-dir</code>	<i>None</i>	Specify the directory where character set information can be found	<i>None</i>
<code>--connect</code> , <code>-</code> <code>--connectstring</code> , or <code>-</code> <code>--ndb-connectstring</code>	<code>-c</code> or <code>-C</code>	Set the connectstring in <code>[nodeid=node_id;][host=]host[:port]</code> format	<code>localhost:1186</code>
<code>--core-file</code>	<i>None</i>	Write a core file in the event of an error	<code>TRUE</code>
<code>--debug</code>	<code>-#</code>	Output debug log	<code>d:t:0,/tmp/ndb_restore.trace</code>
<code>-</code> <code>--dont_ignore_systab_0</code>	<code>-f</code>	Do not ignore system table during restore — <i>EXPERIMENTAL; not for production use</i>	<code>FALSE</code>
<code>--help</code> or <code>--usage</code>	<code>-?</code>	Display help message with available options and current values, then exit	[N/A]
<code>--ndb-mgmd-host</code>	<i>None</i>	Set the host and port in <code>host[:port]</code> format for the management server to connect to; this is the same as <code>--connect</code> , <code>--connectstring</code> , or <code>--ndb-connectstring</code> , but without a way to specify the <code>nodeid</code>	<i>None</i>
<code>--ndb-nodegroup-map</code>	<code>-z</code>	Specifies a nodegroup map — <i>Syntax</i> : list of (<code>source_nodegroup</code> , <code>destination_nodegroup</code>)	<i>None</i>
<code>--ndb-nodeid</code>	<i>None</i>	Specify a node ID for the <code>ndb_restore</code> process	<code>0</code>
<code>-</code> <code>-</code> <code>ndb-optimized-node-selection</code>	<i>None</i>	Optimize selection of nodes for transactions	<code>TRUE</code>
<code>--ndb-shm</code>	<i>None</i>	Use shared memory connections when available	<code>FALSE</code>
<code>-</code> <code>-</code> <code>no-restore-disk-objects</code>	<code>-d</code>	Do not restore Disk Data objects such as tablespaces and log file groups	<code>FALSE</code> (in other words, restore Disk Data objects unless this option is used)
<code>--nodeid</code>	<code>-n</code>	Use backup files from node with the specified ID	<code>0</code>
<code>--parallelism</code>	<code>-p</code>	Set from 1 to 1024 parallel transactions to be used during the restoration process	<code>128</code>
<code>--print</code>	<i>None</i>	Print metadata, data, and log to <code>stdout</code>	<code>FALSE</code>
<code>--print_data</code>	<i>None</i>	Print data to <code>stdout</code>	<code>FALSE</code>
<code>--print_log</code>	<i>None</i>	Print log to <code>stdout</code>	<code>FALSE</code>
<code>--print_meta</code>	<i>None</i>	Print metadata to <code>stdout</code>	<code>FALSE</code>
<code>--restore_data</code>	<code>-r</code>	Restore data and logs	<code>FALSE</code>
<code>--restore_epoch</code>	<code>-e</code>	Restore epoch data into the status table; the row in the <code>cluster.apply_status</code> having the id <code>0</code> is inserted or updated as appropriate — this is convenient when starting up replication on a MySQL Cluster replication slave	<code>FALSE</code>

<code>--restore-meta</code>	<code>-m</code>	Restore table metadata	FALSE
<code>--skip-table-check</code>	<code>-s</code>	Do not check table schemas (Added in MySQL 5.1.17; <i>not supported in MySQL Cluster 5.1 Carrier Grade Edition</i>)	FALSE
<code>--version</code>	<code>-V</code>	Output version information and exit	[N/A]

MySQL Cluster 5.1 Carrier Grade Edition

The following information does not apply to users of MySQL Cluster 5.1 Carrier Grade Edition. For more information about MySQL Cluster 5.1 Carrier Grade Edition, see Section 16.2, “MySQL Cluster 5.1 Carrier Grade Edition”.

Beginning with MySQL 5.1.18, several additional options are available for use with the `--print_data` option in generating data dumps, either to `stdout`, or to a file. These are similar to some of the options used with `mysqldump`, and are shown in the following table:

Long Form	Short Form	Description	Default Value
<code>--tab</code>	<code>-T</code>	Creates dumpfiles, one per table, each named <code>tbl_name.txt</code> . Takes as its argument the path to the directory where the files should be saved (required; use <code>.</code> for the current directory).	None
<code>--fields-enclosed-by</code>	None	String used to enclose all column values	None
<code>--fields-optionally-enclosed-by</code>	None	String used to enclose column values containing character data (such as <code>CHAR</code> , <code>VARCHAR</code> , <code>BINARY</code> , <code>TEXT</code> , or <code>ENUM</code>)	None
<code>--fields-terminated-by</code>	None	String used to separate column values	<code>\t</code> (tab character)
<code>--hex</code>	None	Use hex format for binary values	[N/A]
<code>--lines-terminated-by</code>	None	String used to terminate each line	<code>\n</code> (linefeed character)
<code>--append</code>	None	When used with <code>--tab</code> , causes the data to be appended to existing files of the same name	[N/A]

Note

If a table has no explicit primary key, then the output generated when using the `--print` includes the table's hidden primary key.

Beginning with MySQL 5.1.18, it is possible to restore selected databases, or to restore selected tables from a given database using the syntax shown here:

```
ndb_restore other_options db_name_1 [db_name_2[, db_name_3][, ...] | tbl_name_1[, tbl_name_2][, ...]]
```

In other words, you can specify either of the following to be restored:

- All tables from one or more databases
- One or more tables from a single database

The following information applies to all MySQL Cluster users.

Note

`ndb_restore` reports both temporary and permanent errors. In the case of temporary errors, it may be able to recover from them. Beginning with MySQL 5.1.12, it reports `Restore successful, but encountered temporary error, please look at configuration` in such cases.

16.8.4. Configuration for Cluster Backup

Five configuration parameters are essential for backup:

- **BackupDataBufferSize**
The amount of memory used to buffer data before it is written to disk.
- **BackupLogBufferSize**
The amount of memory used to buffer log records before these are written to disk.
- **BackupMemory**
The total memory allocated in a database node for backups. This should be the sum of the memory allocated for the backup data buffer and the backup log buffer.
- **BackupWriteSize**
The default size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.
- **BackupMaxWriteSize**
The maximum size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

More detailed information about these parameters can be found in [Backup Parameters](#).

16.8.5. Backup Troubleshooting

If an error code is returned when issuing a backup request, the most likely cause is insufficient memory or disk space. You should check that there is enough memory allocated for the backup.

Important

If you have set **BackupDataBufferSize** and **BackupLogBufferSize** and their sum is greater than 4MB, then you must also set **BackupMemory** as well. See **BackupMemory**.

You should also make sure that there is sufficient space on the hard drive partition of the backup target.

NDB does not support repeatable reads, which can cause problems with the restoration process. Although the backup process is “hot”, restoring a MySQL Cluster from backup is not a 100% “hot” process. This is due to the fact that, for the duration of the restore process, running transactions get non-repeatable reads from the restored data. This means that the state of the data is inconsistent while the restore is in progress.

MySQL Enterprise

MySQL Enterprise subscribers will find more information about Cluster backup in the Knowledge Base article, [How Do I Backup my Cluster Database](#). Access to the MySQL Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information see <http://www.mysql.com/products/enterprise/advisors.html>.

16.9. Cluster Utility Programs

This section discusses the MySQL Cluster utility programs that can be found in the `mysql/bin` directory. Each of these — except for `ndb_size.pl` and `ndb_error_reporter` — is a standalone binary that can be used from a system shell, and that does not need to connect to a MySQL server (nor even requires that a MySQL server be connected to the cluster).

These utilities can also serve as examples for writing your own applications using the **NDB** API. The source code for most of these programs may be found in the `storage/ndb/tools` directory of the MySQL 5.1 tree (see [Section 2.9](#), “MySQL Installation Using a

Source Distribution”). The **NDB** API is not covered in this manual; please refer to the [NDB API Guide](#) for information about this API.

All of the **NDB** utilities are listed here with brief descriptions:

- **ndb_config**: Retrieves Cluster configuration option values.
- **ndb_cpcd**: Used in testing and debugging MySQL Cluster.
- **ndb_delete_all**: Deletes all rows from a given table.
- **ndb_desc**: Lists all properties of an **NDB** table.
- **ndb_drop_index**: Drops the specified index from an **NDB** table.
- **ndb_drop_table**: Drops an **NDB** table.
- **ndb_error_reporter**: Can be used to gather information useful for diagnosing problems with the cluster.
- **ndb_mgm**: This is the MySQL Cluster management client, which is discussed in [Section 16.7.2, “Commands in the MySQL Cluster Management Client”](#).
- **ndb_print_backup_file**: Prints diagnostic information obtained from cluster backup files.
- **ndb_print_schema_file**: Prints diagnostic information obtained from cluster schema files.
- **ndb_print_sys_file**: Prints diagnostic information obtained from cluster system files.
- **ndb_restore**: This utility is used to restore a cluster from backup. See [Section 16.8.3, “ndb_restore — Restore a Cluster Backup”](#), for more information.
- **ndb_select_all**: Prints all rows from an **NDB** table.
- **ndb_select_count**: Gets the number of rows in one or more **NDB** tables.
- **ndb_show_tables**: Shows all **NDB** tables anywhere in the cluster.
- **ndb_size.pl**: Examines all the tables in a given non-Cluster database and calculates the amount of storage each would require if it were converted to use the **NDB** storage engine.
- **ndb_waiter**: Reports on the status of cluster data nodes in a manner similar to that of the management client command **ALL STATUS**.
-

MySQL Cluster 5.1 Carrier Grade Edition

The following information applies to users of MySQL Cluster 5.1 Carrier Grade Edition only. For more information about MySQL Cluster 5.1 Carrier Grade Edition, see [Section 16.2, “MySQL Cluster 5.1 Carrier Grade Edition”](#).

ndbd_redo_log_reader: Reads a redo log file, checking it for errors, printing it in a human-readable format, or both.

Note

An alpha version of this utility was made available in MySQL 5.1.15-ndb-6.1.3. Currently, it should be considered experimental.

The following information applies to all MySQL Cluster users.

Most of these utilities need to connect to a Cluster management server in order to function. The exceptions are **ndb_size.pl** (see below), and the following utilities which access a cluster data node filesystem and so need to be run on a data node host:

- **ndb_print_backup_file**
- **ndb_print_schema_file**

- `ndb_print_sys_file`
- `ndbd_redo_log_reader` (*MySQL Cluster 5.1 Carrier Grade Edition only*)

`ndb_size.pl` is a Perl script which is also intended to be used from the shell; however it is a MySQL application and must be able to connect to a MySQL server. See [Section 16.9.15, “ndb_size.pl — NDBCluster Size Requirement Estimator”](#), for additional requirements for using this script.

`ndb_error_reporter` is also a Perl script. It is used to gather cluster data node and management node logs together into a tarball to submit along with a bug report. It can use `ssh` or `scp` to access the node filesystems remotely.

Additional information about each of these utilities (except for `ndb_mgm` and `ndb_restore`) can be found in the sections that follow.

Note

All of these utilities (except for `ndb_size.pl` and `ndb_config`) can use the options discussed in [Section 16.6.5, “Command Options for MySQL Cluster Processes”](#). Additional options specific to each utility program are discussed in the individual program listings.

The order in which these options are used is generally not important. For example, all of these commands produce exactly the same output:

- `ndb_desc -c localhost fish -d test`
- `ndb_desc fish -c localhost -d test`
- `ndb_desc -d test fish -c localhost`

16.9.1. `ndb_config` — Extract NDB Configuration Information

This tool extracts configuration information for data nodes, SQL nodes, and API nodes from a cluster management node (and possibly its `config.ini` file).

Usage:

```
ndb_config options
```

The *options* available for this utility differ somewhat from those used with the other utilities, and so are listed in their entirety in the next section, followed by some examples.

Options:

- `--usage`, `--help`, or `-?`

Causes `ndb_config` to print a list of available options, and then exit.

- `--version`, `-V`

Causes `ndb_config` to print a version information string, and then exit.

- `--ndb-connectstring=connect_string`

Specifies the connectstring to use in connecting to the management server. The format for the connectstring is the same as described in [Section 16.4.4.2, “The Cluster Connectstring”](#), and defaults to `localhost:1186`.

The use of `-c` as a short version for this option is supported for `ndb_config` beginning with MySQL 5.1.12.

- `--config-file=path-to-file`

Gives the path to the management server's configuration file (`config.ini`). This may be a relative or absolute path. If the management node resides on a different host from the one on which `ndb_config` is invoked, then an absolute path must be used.

- `--query=query-options, -q query-options`

This is a comma-delimited list of *query options* — that is, a list of one or more node attributes to be returned. These include `id` (node ID), type (node type — that is, `ndbd`, `mysqld`, or `ndb_mgmd`), and any configuration parameters whose values are to be obtained.

For example, `--query=id,type,indexmemory,datamemory` would return the node ID, node type, `DataMemory`, and `IndexMemory` for each node.

Note

If a given parameter is not applicable to a certain type of node, then an empty string is returned for the corresponding value. See the examples later in this section for more information.

- `--host=hostname`

Specifies the hostname of the node for which configuration information is to be obtained.

- `--id=node_id, --nodeid=node_id`

Used to specify the node ID of the node for which configuration information is to be obtained.

- `--nodes`

(Tells `ndb_config` to print information from parameters defined in `[ndbd]` sections only. Currently, using this option has no affect, since these are the only values checked, but it may become possible in future to query parameters set in `[tcp]` and other sections of cluster configuration files.)

- `--type=node_type`

Filters results so that only configuration values applying to nodes of the specified *node_type* (`ndbd`, `mysqld`, or `ndb_mgmd`) are returned.

- `--fields=delimiter, -f delimiter`

Specifies a *delimiter* string used to separate the fields in the result. The default is “,” (the comma character).

Note

If the *delimiter* contains spaces or escapes (such as `\n` for the linefeed character), then it must be quoted.

- `--rows=separator, -r separator`

Specifies a *separator* string used to separate the rows in the result. The default is a space character.

Note

If the *separator* contains spaces or escapes (such as `\n` for the linefeed character), then it must be quoted.

Examples:

1. To obtain the node ID and type of each node in the cluster:

```
shell> ./ndb_config --query=id,type --fields=':' --rows='\n'
1:ndbd
2:ndbd
3:ndbd
4:ndbd
5:ndb_mgmd
6:mysqld
7:mysqld
8:mysqld
9:mysqld
```

In this example, we used the `--fields` options to separate the ID and type of each node with a colon character (:), and the `--rows` options to place the values for each node on a new line in the output.

- To produce a connectstring that can be used by data, SQL, and API nodes to connect to the management server:

```
shell> ./ndb_config --config-file=/usr/local/mysql/cluster-data/config.ini --query=hostname,portnumber --fields=: --row
192.168.0.179:1186
```

- This invocation of `ndb_config` checks only data nodes (using the `--type` option), and shows the values for each node's ID and hostname, and its `DataMemory`, `IndexMemory`, and `DataDir` parameters:

```
shell> ./ndb_config --type=ndbd --query=id,host,databmemory,indexmemory,datadir -f ' : ' -r '\n'
1 : 192.168.0.193 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
2 : 192.168.0.112 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
3 : 192.168.0.176 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
4 : 192.168.0.119 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
```

In this example, we used the short options `-f` and `-r` for setting the field delimiter and row separator, respectively.

- To exclude results from any host except one in particular, use the `--host` option:

```
shell> ./ndb_config --host=192.168.0.176 -f : -r '\n' -q id,type
3:ndbd
5:ndb_mgmd
```

In this example, we also used the short form `-q` to determine the attributes to be queried.

Similarly, you can limit results to a node with a specific ID using the `--id` or `--nodeid` option.

16.9.2. `ndb_cpcd` — Automate Testing for NDB Development

This utility is found in the `libexec` directory. It is part of an internal automated test framework used in testing and debugging MySQL Cluster. Because it can control processes on remote systems, it is not advisable to use `ndb_cpcd` in a production cluster.

Because some users may be interested in employing the Cluster testing framework for their own development or testing purposes, we intend to make details of this application's usage available in the near future as part of the MySQL Internals Manual.

The source files for `ndb_cpcd` may be found in the directory `storage/ndb/src/cw/cpcd`, in the MySQL 5.1 source tree.

16.9.3. `ndb_delete_all` — Delete All Rows from NDB Table

`ndb_delete_all` deletes all rows from the given NDB table. In some cases, this can be much faster than `DELETE` or even `TRUNCATE`.

Usage:

```
ndb_delete_all -c connect_string tbl_name -d db_name
```

This deletes all rows from the table named `tbl_name` in the database named `db_name`. It is exactly equivalent to executing `TRUNCATE db_name.tbl_name` in MySQL.

Additional Options:

- `--transactional, -t`

Use of this option causes the delete operation to be performed as a single transaction.

Warning

With very large tables, using this option may cause the number of operations available to the cluster to be exceeded.

16.9.4. `ndb_desc` — Describe NDB Tables

`ndb_desc` provides a detailed description of one or more NDB tables.

Usage:

```
ndb_desc -c connect_string tbl_name -d db_name
```

Sample Output:

MySQL table creation and population statements:

```
USE test;

CREATE TABLE fish (
  id INT(11) NOT NULL AUTO_INCREMENT,
  name VARCHAR(20),

  PRIMARY KEY pk (id),
  UNIQUE KEY uk (name)
) ENGINE=NDBCLUSTER;

INSERT INTO fish VALUES
  ('','guppy'), ('','tuna'), ('','shark'),
  ('','manta ray'), ('','grouper'), ('','puffer');
```

Output from `ndb_desc`:

```
shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 16777221
Fragment type: 5
K Value: 6
Min load factor: 78
Max load factor: 80

2          2          2          65536          327680
1          2          2          65536          327680
3          2          2          65536          327680

NDBT_ProgramExit: 0 - OK
```

Additional Options:

- `--extra-partition-info, -p`

Prints additional information about the table's partitions.

- Information about multiple tables can be obtained in a single invocation of `ndb_desc` by using their names, separated by spaces. All of the tables must be in the same database.

16.9.5. `ndb_drop_index` — Drop Index from NDB Table

`ndb_drop_index` drops the specified index from an NDB table. *It is recommended that you use this utility only as an example for writing NDB API applications* — see the Warning later in this section for details.

Usage:

```
ndb_drop_index -c connect_string table_name index -d db_name
```

The statement shown above drops the index named *index* from the *table* in the *database*.

Additional Options: None that are specific to this application.

Warning

Operations performed on Cluster table indexes using the NDB API are not visible to MySQL and make the table unusable by a MySQL server. If you use this program to drop an index, then try to access the table from an SQL node, an error results, as shown here:

```
shell> ./ndb_drop_index -c localhost dogs ix -d ctest1
Dropping index dogs/idx...OK

NDBT_ProgramExit: 0 - OK

shell> ./mysql -u jon -p ctest1
Enter password: *****
Reading table information for completion of table and column names
You can turn off this feature to get a quicker startup with -A

Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 7 to server version: 5.1.12-beta-20060817

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SHOW TABLES;
+-----+
| Tables_in_ctest1 |
+-----+
| a                 |
| bt1               |
| bt2               |
| dogs              |
| employees         |
| fish              |
+-----+
6 rows in set (0.00 sec)

mysql> SELECT * FROM dogs;
ERROR 1296 (HY000): GOT ERROR 4243 'INDEX NOT FOUND' FROM NDBCLUSTER
```

In such a case, your *only* option for making the table available to MySQL again is to drop the table and re-create it. You can use either the SQL statement `DROP TABLE` or the `ndb_drop_table` utility (see [Section 16.9.6, “ndb_drop_table — Drop NDB Table”](#)) to drop the table.

16.9.6. ndb_drop_table — Drop NDB Table

`ndb_drop_table` drops the specified NDB table. (If you try to use this on a table created with a storage engine other than NDB, it fails with the error `723: NO SUCH TABLE EXISTS`.) This operation is extremely fast — in some cases, it can be an order of magnitude faster than using `DROP TABLE` on an NDB table from MySQL.

Usage:

```
ndb_drop_table -c connect_string tbl_name -d db_name
```

Additional Options: None.

16.9.7. ndb_error_reporter — NDB Error-Reporting Utility

`ndb_error_reporter` creates an archive from data node and management node log files that can be used to help diagnose bugs or other problems with a cluster. *It is highly recommended that you make use of this utility when filing reports of bugs in MySQL Cluster.*

Usage:

```
ndb_error_reporter path/to/config-file [username] [--fs]
```

This utility is intended for use on a management node host, and requires the path to the management host configuration file (`config.ini`). Optionally, you can supply the name of a user that is able to access the cluster's data nodes via SSH, in order to copy the data node log files. `ndb_error_reporter` then includes all of these files in archive that is created in the same directory in which it is run. The archive is named `ndb_error_report_YYYYMMDDHHMMSS.tar.bz2`, where `YYYYMMDDHHMMSS` is a datetime string.

If the `--fs` is used, then the data node filesystems are also copied to the management host and included in the archive that is produced by this script. As data node filesystems can be extremely large even after being compressed, we ask that you please do *not* send archives created using this option to MySQL AB unless you are specifically requested to do so.

16.9.8. `ndb_print_backup_file` — Print NDB Backup File Contents

`ndb_print_backup_file` obtains diagnostic information from a cluster backup file.

Usage:

```
ndb_print_backup_file file_name
```

file_name is the name of a cluster backup file. This can be any of the files (`.Data`, `.ctl`, or `.log` file) found in a cluster backup directory. These files are found in the data node's backup directory under the subdirectory `BACKUP-#`, where `#` is the sequence number for the backup. For more information about cluster backup files and their contents, see [Section 16.8.1, “Cluster Backup Concepts”](#).

Like `ndb_print_schema_file` and `ndb_print_sys_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_backup_file` must be run on a cluster data node, since it accesses the data node filesystem directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options: None.

16.9.9. `ndb_print_schema_file` — Print NDB Schema File Contents

`ndb_print_schema_file` obtains diagnostic information from a cluster schema file.

Usage:

```
ndb_print_schema_file file_name
```

file_name is the name of a cluster schema file.

Like `ndb_print_backup_file` and `ndb_print_sys_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_schema_backup_file` must be run on a cluster data node, since it accesses the data node filesystem directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options: None.

16.9.10. `ndb_print_sys_file` — Print NDB System File Contents

`ndb_print_sys_file` obtains diagnostic information from a cluster system file.

Usage:

```
ndb_print_sys_file file_name
```

file_name is the name of a cluster system file (sysfile). Cluster system files are located in a data node's data directory (`DataDir`); the path under this directory to system files matches the pattern `ndb_#_fs/D#/DBDIH/P#.sysfile`. In each case, the `#` represents a number (not necessarily the same number).

Like `ndb_print_backup_file` and `ndb_print_schema_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_backup_file` must be run on a cluster data node, since it accesses the data node filesystem directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options: None.

16.9.11. `ndbd_redo_log_reader` — Check and Print Content of Cluster Redo Log

MySQL Cluster 5.1 Carrier Grade Edition

The information in this section applies to users of MySQL Cluster 5.1 Carrier Grade Edition only. For more information about MySQL Cluster 5.1 Carrier Grade Edition, see Section 16.2, “MySQL Cluster 5.1 Carrier Grade Edition”.

Reads a redo log file, checking it for errors, printing its contents in a human-readable format, or both. `ndbd_redo_log_reader` is intended for use primarily by MySQL developers and support personnel in debugging and diagnosing problems.

This utility was made available as part of the default builds of MySQL Cluster 5.1 Carrier Grade Edition beginning with MySQL 5.1.15-ndb-6.1.3. It remains under development, and its syntax and behavior are subject to change in future releases. For this reason, it should be considered experimental at this time.

The C++ source files for `ndbd_redo_log_reader` can be found in the directory `/storage/ndb/src/kernel/blocks/dblqh/redoLogReader`.

Usage:

```
ndbd_redo_log_reader file_name [options]
```

file_name is the name of a cluster REDO log file. REDO log files are located in the numbered directories under the data node's data directory (`DataDir`); the path under this directory to the REDO log files matches the pattern `ndb_#_fs/D#/LCP/#/T#F#.Data`. In each case, the `#` represents a number (not necessarily the same number).

Additional Options:

The name of the file to be read may be followed by one or more of the options listed here:

- `-noprint`: Do not print the contents of the log file.
- `-nocheck`: Do not check the log file for errors.

Like `ndb_print_backup_file` and `ndb_print_schema_file` (and unlike most of the NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndbd_redo_log_reader` must be run on a cluster data node, since it accesses the data node filesystem directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

16.9.12. `ndb_select_all` — Print Rows from NDB Table

`ndb_select_all` prints all rows from an NDB table to `stdout`.

Usage:

```
ndb_select_all -c connect_string tbl_name -d db_name [> file_name]
```

Additional Options:

- `--lock=lock_type, -l lock_type`

Employs a lock when reading the table. Possible values for *lock_type* are:

- `0`: Read lock
- `1`: Read lock with hold
- `2`: Exclusive read lock

There is no default value for this option.

- `--order=index_name, -o index_name`

Orders the output according to the index named *index_name*. Note that this is the name of an index, not of a column, and that the index must have been explicitly named when created.

- `--descending, -z`
Sorts the output in descending order. This option can be used only in conjunction with the `-o (--order)` option.
- `--header=FALSE`
Excludes column headers from the output.
- `--useHexFormat -x`
Causes all numeric values to be displayed in hexadecimal format. This does not affect the output of numerals contained in strings or datetime values.
- `--delimiter=character, -D character`
Causes the *character* to be used as a column delimiter. Only table data columns are separated by this delimiter.
The default delimiter is the tab character.
- `--disk`
Adds a disk reference column to the output. The column is non-empty only for Disk Data tables having non-indexed columns.
- `--rowid`
Adds a `ROWID` column providing information about the fragments in which rows are stored.
- `--gci`
Adds a column to the output showing the global checkpoint at which each row was last updated. See [Section 16.15, “MySQL Cluster Glossary”](#), and [Section 16.7.3.2, “Log Events”](#), for more information about checkpoints.
- `--tupscan, -t`
Scan the table in the order of the tuples.
- `--nodata`
Causes any table data to be omitted.

Sample Output:

Output from a MySQL `SELECT` statement:

```
mysql> SELECT * FROM ctest1.fish;
+----+-----+
| id | name |
+----+-----+
| 3  | shark|
| 6  | puffer|
| 2  | tuna |
| 4  | manta ray|
| 5  | grouper|
| 1  | guppy|
+----+-----+
6 rows in set (0.04 sec)
```

Output from the equivalent invocation of `ndb_select_all`:

```
shell> ./ndb_select_all -c localhost fish -d ctest1
id      name
3       [shark]
6       [puffer]
2       [tuna]
4       [manta ray]
5       [grouper]
1       [guppy]
6 rows returned
NDBT_ProgramExit: 0 - OK
```

Note that all string values are enclosed by square brackets (“[...]”) in the output of `ndb_select_all`. For a further example, consider the table created and populated as shown here:

```
CREATE TABLE dogs (
  id INT(11) NOT NULL AUTO_INCREMENT,
  name VARCHAR(25) NOT NULL,
  breed VARCHAR(50) NOT NULL,
  PRIMARY KEY pk (id),
  KEY ix (name)
)
TABLESPACE ts STORAGE DISK
ENGINE=NDB;

INSERT INTO dogs VALUES
  ('', 'Lassie', 'collie'),
  ('', 'Scooby-Doo', 'Great Dane'),
  ('', 'Rin-Tin-Tin', 'Alsatian'),
  ('', 'Rosscoe', 'Mutt');
```

This demonstrates the use of several additional `ndb_select_all` options:

```
shell> ./ndb_select_all -d ctest1 dogs -o ix -z --gci --disk
GCI      id name      breed      DISK_REF
834461   2 [Scooby-Doo] [Great Dane] [ m_file_no: 0 m_page: 98 m_page_idx: 0 ]
834878   4 [Rosscoe]   [Mutt]      [ m_file_no: 0 m_page: 98 m_page_idx: 16 ]
834463   3 [Rin-Tin-Tin] [Alsatian] [ m_file_no: 0 m_page: 34 m_page_idx: 0 ]
835657   1 [Lassie]    [Collie]    [ m_file_no: 0 m_page: 66 m_page_idx: 0 ]
4 rows returned

NDBT_ProgramExit: 0 - OK
```

16.9.13. `ndb_select_count` — Print Row Counts for NDB Tables

`ndb_select_count` prints the number of rows in one or more NDB tables. With a single table, the result is equivalent to that obtained by using the MySQL statement `SELECT COUNT(*) FROM tbl_name`.

Usage:

```
ndb_select_count [-c connect_string] -ddb_name tbl_name [, tbl_name2 [, ...]]
```

Additional Options: None that are specific to this application. However, you can obtain row counts from multiple tables in the same database by listing the table names separated by spaces when invoking this command, as shown under **Sample Output**.

Sample Output:

```
shell> ./ndb_select_count -c localhost -d ctest1 fish dogs
6 records in table fish
4 records in table dogs

NDBT_ProgramExit: 0 - OK
```

16.9.14. `ndb_show_tables` — Display List of NDB Tables

`ndb_show_tables` displays a list of all NDB database objects in the cluster. By default, this includes not only both user-created tables and NDB system tables, but NDB-specific indexes, internal triggers, and Cluster Disk Data objects as well.

Usage:

```
ndb_show_tables [-c connect_string]
```

Additional Options:

- `--loops, -l`

Specifies the number of times the utility should execute. This is 1 when this option is not specified, but if you do use the option, you must supply an integer argument for it.

- `--parsable, -p`

Using this option causes the output to be in a format suitable for use with [LOAD DATA INFILE](#).

- `--type, -t`

Can be used to restrict the output to one type of object, specified by an integer type code as shown here:

- 1: System table
- 2: User-created table
- 3: Unique hash index

Any other value causes all [NDB](#) database objects to be listed (the default).

- `--unqualified, -u`

If specified, this causes unqualified object names to be displayed.

Note

Only user-created Cluster tables may be accessed from MySQL; system tables such as [SYSTAB_0](#) are not visible to [mysqld](#). However, you can examine the contents of system tables using [NDB](#) API applications such as [ndb_select_all](#) (see [Section 16.9.12, “ndb_select_all — Print Rows from NDB Table”](#)).

16.9.15. [ndb_size.pl](#) — NDBCluster Size Requirement Estimator

This is a Perl script that can be used to estimate the amount of space that would be required by a MySQL database if it were converted to use the [NDBCluster](#) storage engine. Unlike the other utilities discussed in this section, it does not require access to a MySQL Cluster (in fact, there is no reason for it to do so). However, it does need to access the MySQL server on which the database to be tested resides.

Requirements:

- A running MySQL server. The server instance does not have to provide support for MySQL Cluster.
- A working installation of Perl.
- The [DBI](#) module, which can be obtained from CPAN if it is not already part of your Perl installation. (Many Linux and other operating system distributions provide their own packages for this library.)

Note

Previous to MySQL 5.1.18, [ndb_size.pl](#) also required the [HTML::Template](#) module.

- The [ndb_size.tmpl](#) template file, which you should be able to find in the [share/mysql](#) directory of your MySQL installation. This file should be copied or moved into the same directory as [ndb_size.pl](#) — if it is not there already — before running the script.
- A MySQL user account having the necessary privileges. If you do not wish to use an existing account, then creating one using [GRANT USAGE ON db_name.*](#) — where [db_name](#) is the name of the database to be examined — is sufficient for this purpose.

[ndb_size.pl](#) and [ndb_size.tmpl](#) can also be found in the MySQL sources in [storage/ndb/tools](#). If these files are not present in your MySQL installation, you can obtain them from the [MySQLForge project page](#).

Usage:

```
perl ndb_size.pl db_name hostname username password > file_name.html
```

The command shown connects to the MySQL server at [hostname](#) using the account of the user [username](#) having the password [password](#), analyses all of the tables in database [db_name](#), and generates a report in HTML format which is directed to the file

file_name.html. (Without the redirection, the output is sent to *stdout*.) This figure shows partial sample output as viewed in a Web browser:

MySQL Cluster analysis for world

This is an automated analysis of the DBI:mysql:database=world;host=192.168.0.176 database for migration into MySQL Cluster. No warranty is made to the accuracy of the information.

This information should be valid for MySQL 4.1 and 5.0. Since 5.1 is not a final release yet, the numbers should be used as a guide only.

Parameter Settings

NOTE the configuration parameters below do not take into account system tables and other requirements.

Parameter	4.1	5.0	5.1
DataMemory (kb)	544	544	544
IndexMemory (kb)	192	136	136
MaxNoOfTables	3	3	3
MaxNoOfAttributes	24	24	24
MaxNoOfOrderedIndexes	3	3	3
MaxNoOfUniqueHashIndexes	3	3	3
MaxNoOfTriggers	12	12	12

Memory usage because of parameters

Usage is in kilobytes. Actual usage will vary as you should set the parameters larger than those listed in the table above.

Parameter	4.1	5.0	5.1
Attributes	5	5	5
Tables	60	60	60
OrderedIndexes	30	30	30
UniqueHashIndexes	45	45	45

Table List

- [City](#)
- [Country](#)
- [CountryLanguage](#)

City

Column	Type	Size	Key	4.1 NDB Size	5.0 NDB Size	5.1 NDB Size
ID	int	11	PRI	4	4	4
District	char	20		20	20	20
Name	char	35		36	36	36
Population	int	11		4	4	4
CountryCode	char	3		4	4	4

Indexes

We assume that indexes are ORDERED (not created USING HASH). If order is not required, 10 bytes of data memory can be saved per row if the index is created USING HASH

Index	Type	Columns	4.1 IdxMem	5.0 IdxMem	5.1 IdxMem	4.1 DatMem	5.0 DatMem	5.1 DatMem
PRIMARY	BTREE	ID	29	25	25	10	10	10

DataMemory Usage

	4.1	5.0	5.1
Row Overhead	16	16	16
Column DataMemory/Row	68	68	68
Index DataMemory/Row	10	10	10
Total DataMemory/Row	94	94	94
Rows per 32 kb page	347	347	347
Current number of rows	4079	4079	4079
Total DataMemory (kb)	384	384	384

IndexMemory Usage

	4.1	5.0	5.1
IndexMemory/Row	29	25	25
Rows per 8kb page	282	327	327
Current number of rows	4079	4079	4079
Total IndexMemory (kb)	120	104	104

The output from this script includes:

- Minimum values for the `DataMemory`, `IndexMemory`, `MaxNoOfTables`, `MaxNoOfAttributes`, `MaxNoOfOrderedIndexes`, `MaxNoOfUniqueHashIndexes`, and `MaxNoOfTriggers` configuration parameters required to accommodate the tables analysed.
- Memory requirements for all of the tables, attributes, ordered indexes, and unique hash indexes defined in the database.
- The `IndexMemory` and `DataMemory` required per table and table row.

MySQL Cluster 5.1 Carrier Grade Edition

The following information applies to users of MySQL Cluster 5.1 Carrier Grade Edition only. For more information about MySQL Cluster 5.1 Carrier Grade Edition, see Section 16.2, “MySQL Cluster 5.1 Carrier Grade Edition”.

Beginning with MySQL 5.1.22-ndb-6.2.5, the behavior of this utility and its available options have changed. ([Bug#28683](#), [Bug#28253](#))

Typical usage is shown here:

```
ndb_size.pl [--database=db_name|ALL] [--hostname=host[:port]] [--socket=socket] [--user=user] [--password=password] [--help]
```

Important

`ndb_size.pl` now takes named options, each of which is optional.

By default, this utility attempts to analyze all databases on the server. You can specify a single database using the `--database` option; the default behavior can be made explicit by using `ALL` for the name of the database. You can also exclude one or more databases by using the `--excludedbs` with a comma-separated list of the names of the databases to be skipped. Similarly, you can cause specific tables to be skipped by listing their names, separated by commas, following the optional `--excludetables` option. A host-name (and possibly a port as well) can be specified using `--hostname`; the default is `localhost:3306`. If necessary, you can specify a socket; the default is `/var/lib/mysql.sock`. A MySQL username and password can be specified the corresponding options shown. It also possible to control the format of the output using the `--format` option; this can take either of the values `html` or `text`, with `text` being the default. An example of the text output is shown here:

```
shell> ndb_size.pl --database=test --socket=/tmp/mysql.sock
ndb_size.pl report for database: 'test' (1 tables)
-----
Connected to: DBI:mysql:host=localhost;mysql_socket=/tmp/mysql.sock
Including information for versions: 4.1, 5.0, 5.1

test.t1
-----

For debugging purposes, the Perl arrays containing the queries run by this script can be read from the file specified using `--savequeries`; a file containing such arrays to be read in during script execution can be specified using `--loadqueries`. Neither of these options has a default value.

The following information applies to all MySQL Cluster users.

16.9.16. `ndb_waiter` — Wait for Cluster to Reach a Given Status

`ndb_waiter` repeatedly (each 100 milliseconds) prints out the status of all cluster data nodes until either the cluster reaches a given status or the `--timeout` limit is exceeded, then exits. By default, it waits for the cluster to achieve `STARTED` status, in which all nodes have started and connected to the cluster. This can be overridden using the `--no-contact` and `--not-started` options (see [Additional Options](#)).

The node states reported by this utility are as follows:

- **NO_CONTACT**: The node cannot be contacted.
- **UNKNOWN**: The node can be contacted, but its status is not yet known. Usually, this means that the node has received a `START` or `RESTART` command from the management server, but has not yet acted on it.
- **NOT_STARTED**: The node has stopped, but remains in contact with the cluster. This is seen when restarting the node using the management client's `RESTART` command.
- **STARTING**: The node's `ndbd` process has started, but the node has not yet joined the cluster.
- **STARTED**: The node is operational, and has joined the cluster.
- **SHUTTING_DOWN**: The node is shutting down.
- **SINGLE USER MODE**: This is shown for all cluster data nodes when the cluster is in single user mode.

Usage:

```
ndb_waiter [-c connect_string]
```

Additional Options:

- `--no-contact, -n`

Instead of waiting for the `STARTED` state, `ndb_waiter` continues running until the cluster reaches `NO_CONTACT` status before exiting.

- `--not-started`

Instead of waiting for the `STARTED` state, `ndb_waiter` continues running until the cluster reaches `NOT_STARTED` status before exiting.

- `--timeout=seconds, -t seconds`

Time to wait. The program exits if the desired state is not achieved within this number of seconds. The default is 120 seconds (1200 reporting cycles).

Sample Output. Shown here is the output from `ndb_waiter` when run against a 4-node cluster in which two nodes have been shut down and then started again manually. Duplicate reports (indicated by “...”) are omitted.

```
shell> ./ndb_waiter -c localhost
Connecting to mgmsrv at (localhost)
State node 1 STARTED
State node 2 NO_CONTACT
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED
...
State node 1 STARTED
State node 2 UNKNOWN
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED
...
State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED
...
State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 UNKNOWN
Waiting for cluster enter state STARTED
...
State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED
...
State node 1 STARTED
State node 2 STARTED
State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED
...
State node 1 STARTED
State node 2 STARTED
State node 3 STARTED
State node 4 STARTED
Waiting for cluster enter state STARTED
NDBT_ProgramExit: 0 - OK
```

Note

If no connectstring is specified, then `ndb_waiter` tries to connect to a management on `localhost`, and reports `Connecting to mgmsrv at (null)`.

16.10. MySQL Cluster Replication

Previous to MySQL 5.1.6, *asynchronous replication*, more usually referred to simply as “replication”, was not available when using

MySQL Cluster. MySQL 5.1.6 introduces master-slave replication of this type for MySQL Cluster databases. This section explains how to set up and manage a configuration wherein one group of computers operating as a MySQL Cluster replicates to a second computer or group of computers. We assume some familiarity on the part of the reader with standard MySQL replication as discussed elsewhere in this Manual. (See [Chapter 15, Replication](#)).

Normal (non-clustered) replication involves a “master” server and a “slave” server, the master being the source of the operations and data to be replicated and the slave being the recipient of these. In MySQL Cluster, replication is conceptually very similar but can be more complex in practice, as it may be extended to cover a number of different configurations including replicating between two complete clusters. Although a MySQL Cluster itself depends on the [NDB Cluster](#) storage engine for clustering functionality, it is not necessary to use the Cluster storage engine on the slave. However, for maximum availability, it is possible to replicate from one MySQL Cluster to another, and it is this type of configuration that we discuss, as shown in the following figure:

In this scenario, the replication process is one in which successive states of a master cluster are logged and saved to a slave cluster. This process is accomplished by a special thread known as the NDB binlog injector thread, which runs on each MySQL server and produces a binary log ([binlog](#)). This thread ensures that all changes in the cluster producing the binary log — and not just those changes that are effected via the MySQL Server — are inserted into the binary log with the correct serialization order. We refer to the MySQL replication master and replication slave servers as replication servers or replication nodes, and the data flow or line of communication between them as a *replication channel*.

16.10.1. Abbreviations and Symbols

Throughout this section, we use the following abbreviations or symbols for referring to the master and slave clusters, and to processes and commands run on the clusters or cluster nodes:

Symbol or Abbreviation	Description (Refers to...)
<i>M</i>	The cluster serving as the (primary) replication master
<i>S</i>	The cluster acting as the (primary) replication slave
<code>shellM></code>	Shell command to be issued on the master cluster
<code>mysqlM></code>	MySQL client command issued on a single MySQL server running as an SQL node on the master cluster
<code>mysqlM*></code>	MySQL client command to be issued on all SQL nodes participating in the replication master cluster
<code>shellS></code>	Shell command to be issued on the slave cluster
<code>mysqlS></code>	MySQL client command issued on a single MySQL server running as an SQL node on the slave cluster

<code>mysqls*></code>	MySQL client command to be issued on all SQL nodes participating in the replication slave cluster
<code>C</code>	Primary replication channel
<code>C'</code>	Secondary replication channel
<code>M'</code>	Secondary replication master
<code>S'</code>	Secondary replication slave

16.10.2. Assumptions and General Requirements

A replication channel requires two MySQL servers acting as replication servers (one each for the master and slave). For example, this means that in the case of a replication setup with two replication channels (to provide an extra channel for redundancy), there will be a total of four replication nodes, two per cluster.

Replication of a MySQL Cluster as described in this section and those following is dependent on row-based replication. This means that the replication master MySQL server must be started with `--binlog-format=row`, as described in [Section 16.10.6, “Starting Replication \(Single Replication Channel\)”](#). For general information about row-based replication, see [Section 15.1.2, “Replication Formats”](#).

(It is possible to replicate a MySQL Cluster using statement-based replication. However, in this case, the following restrictions apply: All updates to data rows on the cluster acting as the master must be directed to a single MySQL server; It is not possible to replicate a cluster using several MySQL replication processes at the same time; Only changes made at the SQL level are replicated.)

Each MySQL server used for replication in either cluster must be uniquely identified among all the MySQL replication servers participating in either cluster (you cannot have replication servers on both the master and slave clusters sharing the same ID). This can be done by starting each SQL node using the `--server-id=id` option, where `id` is a unique integer. Although it is not strictly necessary, we will assume for purposes of this discussion that all MySQL installations are the same version.

In any event, both MySQL servers involved in replication must be compatible with one another with respect to both the version of the replication protocol used and the SQL feature sets which they support; the simplest and easiest way to assure that this is the case is to use the same MySQL version for all servers involved. Note that in many cases it is not possible to replicate to a slave running a version of MySQL with a lower version number than that of the master — see [Section 15.3.2, “Replication Compatibility Between MySQL Versions”](#), for details.

We assume that the slave server or cluster is dedicated to replication of the master, and that no other data is being stored on it.

16.10.3. Known Issues in MySQL Cluster Replication

The following are known problems or issues when using replication with MySQL Cluster in MySQL 5.1:

- **Loss of master-slave connection.** Prior to MySQL 5.1.18, a MySQL Cluster replication slave `mysqlsld` had no way of detecting that the connection from the master had been interrupted (due to, for instance, the master going down or a network failure). For this reason, it was possible for the slave to become inconsistent with the master.

Beginning with MySQL 5.1.18, the master issues a “gap” event when connecting to the cluster. When the slave encounters a gap in the replication log, it stops with an error message. This message is available in the output of `SHOW SLAVE STATUS`, and indicates that the SQL thread has stopped due to an incident registered in the replication stream, and that manual intervention is required. In order to restart the slave, it is necessary to issue the following commands:

```
SET GLOBAL SQL_SLAVE_SKIP_COUNTER = 1;
START SLAVE;
```

The slave then resumes reading the master binlog from the point where the gap was recorded.

(If high availability is a requirement for the slave server or cluster, then it is still advisable to set up multiple replication lines, to monitor the master `mysqlsld` on the primary replication line, and to fail over to a secondary line if and as necessary. For information about implementing this type of setup, see [Section 16.10.7, “Using Two Replication Channels”](#), and [Section 16.10.8, “Implementing Failover with MySQL Cluster”](#).)

- **Multi-byte character sets.** There are several known issues with regard to the use of multi-byte characters sets with MySQL Cluster Replication. See [Bug#27404](#) (fixed in MySQL 5.1.21), [Bug#29562](#), [Bug#29563](#), and [Bug#29564](#) for more information.
- **Circular replication.** Prior to MySQL 5.1.18, circular replication was not supported with MySQL Cluster replication, due to the fact that all log events created in a particular MySQL Cluster were wrongly tagged with the server ID of the MySQL server used as

master and not with the server ID of the originating server.

MySQL Cluster 5.1 Carrier Grade Edition

The following information does not apply to users of MySQL Cluster 5.1 Carrier Grade Edition. For more information about MySQL Cluster 5.1 Carrier Grade Edition, see Section 16.2, “MySQL Cluster 5.1 Carrier Grade Edition”.

Beginning with MySQL 5.1.18, this limitation is lifted, as discussed in the next few paragraphs, in which we consider the example of a replication setup involving three MySQL Clusters numbered 1, 2, and 3, in which Cluster 1 acts as the replication master for Cluster 2, Cluster 2 acts as the master for Cluster 3, and Cluster 3 acts as the master for Cluster 1. Each cluster has two SQL nodes, with SQL nodes A and B belonging to Cluster 1, SQL nodes C and D belonging to Cluster 2, and SQL nodes E and F belonging to Cluster 3.

Circular replication using these clusters is supported as long as:

- the SQL nodes on all masters and slaves are the same
- All SQL nodes acting as replication masters and slaves are started using the `--log-slave-updates` option

This type of circular replication setup is shown in the following diagram:

In this scenario, SQL node A in Cluster 1 replicates to SQL node C in Cluster 2; SQL node C replicates to SQL node E in Cluster 3; SQL node E replicates to SQL node A. In other words, the replication line (indicated by the red arrows in the diagram) directly connects all SQL nodes used as replication masters and slaves.

It should also be possible to set up circular replication in which not all master SQL nodes are also slaves, as shown here:

In this case, different SQL nodes in each cluster are used as replication masters and slaves. However, you must *not* start any of the SQL nodes using `--log-slave-updates` (see the [description of this option](#) for more information). This type of circular replication scheme for MySQL Cluster, in which the line of replication (again indicated by the red arrows in the diagram) is discontinuous, should be possible, but it should be noted that it has not yet been thoroughly tested and must therefore still be considered experimental.

The following information applies to all MySQL Cluster users.

- **DDL statements.** The use of data definition statements, such as `CREATE TABLE`, `DROP TABLE`, and `ALTER TABLE`, are recor-

ded in the binary log for only the MySQL server on which they are issued.

- **Explicit primary key required.** In MySQL 5.1.6, only those **NDB** tables having explicit primary keys could be replicated. This limitation was lifted in MySQL 5.1.7.
- **Restarting with `--initial`.** Restarting the cluster with the `--initial` option causes the sequence of GCI and epoch numbers to start over from 0. (This is generally true of MySQL Cluster and not limited to replication scenarios involving Cluster.) The MySQL servers involved in replication should in this case be restarted. After this, you should use the **RESET MASTER** and **RESET SLAVE** statements to clear the invalid `ndb_binlog_index` and `ndb_apply_status` tables, respectively.
- **`auto_increment_offset` and `auto_increment_increment` variables.** The use of the `auto_increment_offset` and `auto_increment_increment` server system variables is supported beginning with MySQL 5.1.20. Previously, these produced unpredictable results when used with **NDB** tables or MySQL Cluster replication.
- **Replication from **NDB** to other storage engines.** If you attempt to replicate from a MySQL Cluster to a slave that uses a storage engine that does not handle its own binary logging, the replication process aborts with the error **BINARY LOGGING NOT POSSIBLE ... STATEMENT CANNOT BE WRITTEN ATOMICALLY SINCE MORE THAN ONE ENGINE INVOLVED AND AT LEAST ONE ENGINE IS SELF-LOGGING** (Error 1595). It is possible to work around this issue in one of the following ways:
 - **Turn off binary logging on the slave.** This can be accomplished by setting `SQL_BIN_LOG = 0`.
 - **Change the storage engine used for the `mysql.ndb_apply_status` table.** Causing this table to use an engine that does not handle its own binary logging can also eliminate the conflict. This can be done by issuing a statement such as **ALTER TABLE `mysql.ndb_apply_status` ENGINE=MyISAM** on the slave. It is safe to do this when using a non-**NDB** storage engine on the slave, since you do not then need to worry about keeping multiple slave SQL nodes synchronized.
 - **Filter out changes to the `mysql.ndb_apply_status` table on the slave.** This can be done by starting the slave SQL node with the option `--replicate-ignore-table=mysql.ndb_apply_status`. If you need for other tables to be ignored by replication, you might wish to use an appropriate `--replicate-wild-ignore-table` option instead.

16.10.4. Cluster Replication Schema and Tables

Replication in MySQL Cluster makes use of a number of dedicated tables in the `mysql` database on each MySQL Server instance acting as an SQL node in both the cluster being replicated and the replication slave (whether the slave is a single server or a cluster). These tables are created during the MySQL installation process by the `mysql_install_db` script, and include a table for storing the binary log's indexing data. Since the `ndb_binlog_index` table is local to each MySQL server and does not participate in clustering, it uses the **MyISAM** storage engine. This means that it must be created separately on each `mysqld` participating in the master cluster. (However, the binlog itself contains updates from all MySQL servers in the cluster to be replicated.) This table is defined as follows:

```
CREATE TABLE `ndb_binlog_index` (
  `Position` BIGINT(20) UNSIGNED NOT NULL,
  `File` VARCHAR(255) NOT NULL,
  `epoch` BIGINT(20) UNSIGNED NOT NULL,
  `inserts` BIGINT(20) UNSIGNED NOT NULL,
  `updates` BIGINT(20) UNSIGNED NOT NULL,
  `deletes` BIGINT(20) UNSIGNED NOT NULL,
  `schemaops` BIGINT(20) UNSIGNED NOT NULL,
  PRIMARY KEY (`epoch`)
) ENGINE=MYISAM DEFAULT CHARSET=latin1;
```

Important

Prior to MySQL 5.1.14, the `ndb_binlog_index` table was known as `binlog_index`, and was kept in a separate `cluster` database, which in MySQL 5.1.7 and earlier was known as the `cluster_replication` database. Similarly, the `ndb_apply_status` and `ndb_schema` tables were known as `apply_status` and `schema`, and were also found in the `cluster` (earlier `cluster_replication`) database. However, beginning with MySQL 5.1.14, all MySQL Cluster replication tables reside in the `mysql` system database.

Information about how this change affects upgrades from MySQL Cluster 5.1.13 and earlier to 5.1.14 and later versions can be found in [Section C.1.15, “Changes in release 5.1.14 \(05 December 2006\)”](#).

The following figure shows the relationship of the MySQL Cluster replication master server, its binlog injector thread, and the `mysql.ndb_binlog_index` table.

[REDACTED]

However, it is advisable to check for the existence and integrity of these tables as an initial step in preparing a MySQL Cluster for replication. It is possible to view event data recorded in the binary log by querying the `mysql.binlog_index` table directly on the master. This can be also be accomplished using the `SHOW BINLOG EVENTS` statement on either the replication master or slave MySQL servers. (See [Section 12.6.1.4, “SHOW BINLOG EVENTS Syntax”](#).)

You can also obtain useful information from the output of `SHOW ENGINE NDB STATUS`.

Note

Beginning with MySQL 5.1.14, if the `apply_status` table does not exist on the slave, it is created by `ndb_restore`. ([Bug#14612](#))

16.10.5. Preparing the Cluster for Replication

Preparing the MySQL Cluster for replication consists of the following steps:

1. Check all MySQL servers for version compatibility (see [Section 16.10.2, “Assumptions and General Requirements”](#)).
2. Create a slave account on the master Cluster with the appropriate privileges:

```
mysqlM> GRANT REPLICATION SLAVE
-> ON *.* TO 'slave_user'@'slave_host'
-> IDENTIFIED BY 'slave_password';
```

In the previous statement, `slave_user` is the slave account username, `slave_host` is the hostname or IP address of the replication slave, and `slave_password` is the password to assign to this account.

For example, to create a slave user account with the name “`myslave`,” logging in from the host named “`rep-slave`,” and using the password “`53cr37`,” use the following `GRANT` statement:

```
mysqlM> GRANT REPLICATION SLAVE
-> ON *.* TO 'myslave'@'rep-slave'
-> IDENTIFIED BY '53cr37';
```

For security reasons, it is preferable to use a unique user account — not employed for any other purpose — for the replication slave account.

3. Configure the slave to use the master. Using the MySQL Monitor, this can be accomplished with the `CHANGE MASTER TO` statement:

```
mysqlS> CHANGE MASTER TO
-> MASTER_HOST='master_host',
-> MASTER_PORT=master_port,
-> MASTER_USER='slave_user',
-> MASTER_PASSWORD='slave_password';
```

In the previous statement, `master_host` is the hostname or IP address of the replication master, `master_port` is the port for the slave to use for connecting to the master, `slave_user` is the username set up for the slave on the master, and `slave_password` is the password set for that user account in the previous step.

For example, to tell the slave to replicate from the MySQL server whose hostname is “`rep-master`,” using the replication slave account created in the previous step, use the following statement:

```
mysqlS> CHANGE MASTER TO
-> MASTER_HOST='rep-master'
-> MASTER_PORT=3306,
-> MASTER_USER='myslave'
-> MASTER_PASSWORD='53cr37';
```

(For a complete list of clauses that can be used with this statement, see [Section 12.6.2.1, “CHANGE MASTER TO Syntax”](#).)

You can also configure the slave to use the master by setting the corresponding startup options in the slave server's `my.cnf` file. To configure the slave in the same way as the preceding example `CHANGE MASTER TO` statement, the following information would need to be included in the slave's `my.cnf` file:

```
[mysqld]
```

```
master-host=rep-master
master-port=3306
master-user=myslave
master-password=53cr37
```

See [Section 15.1.3, “Replication Options and Variables”](#), for additional options that can be set in `my.cnf` for replication slaves.

Note

To provide replication backup capability, you will also need to add an `ndb-connectstring` option to the slave's `my.cnf` file prior to starting the replication process. See [Section 16.10.9, “MySQL Cluster Backups With Replication”](#), for details.

4. If the master cluster is already in use, you can create a backup of the master and load this onto the slave to cut down on the amount of time required for the slave to synchronize itself with the master. If the slave is also running MySQL Cluster, this can be accomplished using the backup and restore procedure described in [Section 16.10.9, “MySQL Cluster Backups With Replication”](#).

```
ndb-connectstring=management_host[:port]
```

In the event that you are *not* using MySQL Cluster on the replication slave, you can create a backup with this command on the replication master:

```
shellM> mysqldump --master-data=1
```

Then import the resulting data dump onto the slave by copying the dump file over to the slave. After this, you can use the `mysql` client to import the data from the dumpfile into the slave database as shown here, where `dump_file` is the name of the file that was generated using `mysqldump` on the master, and `db_name` is the name of the database to be replicated:

```
shellS> mysql -u root -p db_name < dump_file
```

For a complete list of options to use with `mysqldump`, see [Section 7.13, “mysqldump — A Database Backup Program”](#).

Note

If you copy the data to the slave in this fashion, you should make sure that the slave is started with the `-skip-slave-start` option on the command line, or else include `skip-slave-start` in the slave's `my.cnf` file to keep it from trying to connect to the master to begin replicating before all the data has been loaded. Once the data load-in has completed, follow the additional steps outlined in the next two sections.

5. Ensure that each MySQL server acting as a replication master is configured with a unique server ID, and with binary logging enabled, using the row format. (See [Section 15.1.2, “Replication Formats”](#).) These options can be set either in the master server's `my.cnf` file, or on the command line when starting the master `mysqld` process. See [Section 16.10.6, “Starting Replication \(Single Replication Channel\)”](#), for information regarding the latter option.

16.10.6. Starting Replication (Single Replication Channel)

This section outlines the procedure for starting MySQL Cluster replication using a single replication channel.

1. Start the MySQL replication master server by issuing this command:

```
shellM> mysqld --ndbcluster --server-id=id \
--log-bin --binlog-format=row &
```

In the previous statement, `id` is this server's unique ID (see [Section 16.10.2, “Assumptions and General Requirements”](#)). This starts the server's `mysqld` process with binary logging enabled using the proper logging format.

2. Start the MySQL replication slave server as shown here:

```
shellS> mysqld --ndbcluster --server-id=id &
```

In the previous statement, `id` is the slave server's unique ID. It is not necessary to enable logging on the replication slave.

Note

You should use the `--skip-slave-start` option with this command or else you should include `skip-slave-start` in the slave server's `my.cnf` file, unless you want replication to begin immediately. With the use of this option, the start of replication is delayed until the appropriate `START SLAVE` statement has been issued, as explained in Step 4 below.

- It is necessary to synchronize the slave server with the master server's replication binlog. If binary logging has not previously been running on the master, run the following statement on the slave:

```
mysql> CHANGE MASTER TO
-> MASTER_LOG_FILE=' ',
-> MASTER_LOG_POS=4;
```

This instructs the slave to begin reading the master's binary log from the log's starting point. Otherwise — that is, if you are loading data from the master using a backup — see [Section 16.10.8, “Implementing Failover with MySQL Cluster”](#), for information on how to obtain the correct values to use for `MASTER_LOG_FILE` and `MASTER_LOG_POS` in such cases.

- Finally, you must instruct the slave to begin applying replication by issuing this command from the `mysql` client on the replication slave:

```
mysql> START SLAVE;
```

This also initiates the transmission of replication data from the master to the slave.

It is also possible to use two replication channels, in a manner similar to the procedure described in the next section; the differences between this and using a single replication channel are covered in [Section 16.10.7, “Using Two Replication Channels”](#).

MySQL Cluster 5.1 Carrier Grade Edition

The following information applies to users of MySQL Cluster 5.1 Carrier Grade Edition only. For more information about MySQL Cluster 5.1 Carrier Grade Edition, see [Section 16.2, “MySQL Cluster 5.1 Carrier Grade Edition”](#).

Beginning with MySQL 5.1.19-ndb-6.2.3, it is possible to improve cluster replication performance by enabling *batched updates*. This can be accomplished by starting slave `mysqld` processes with the `--slave-allow-batching` option. Normally, updates are applied as soon as they are received. However, the use of batching causes updates to be applied in 32 KB batches, which can result in higher throughput and less CPU usage, particularly where individual updates are relatively small.

Note

Slave batching works on a per-epoch basis; updates belonging to more than one transaction can be sent as part of the same batch.

All outstanding updates are applied when the end of an epoch is reached, even if the updates total less than 32 KB.

Batching can be turned on and off at runtime. To activate it at runtime, you can use either of these two statements:

```
SET GLOBAL slave_allow_batching = 1;
SET GLOBAL slave_allow_batching = ON;
```

If a particular batch causes problems (such as a statement whose effects do not appear to be replicated correctly), slave batching can be deactivated using either of the following statements:

```
SET GLOBAL slave_allow_batching = 0;
SET GLOBAL slave_allow_batching = OFF;
```

You can check whether slave batching is currently being used by means of an appropriate `SHOW VARIABLES` statement, like this one:

```
mysql> SHOW VARIABLES LIKE 'slave%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| slave_allow_batching | ON    |
| slave_compressed_protocol | OFF   |
| slave_load_tmpdir | /tmp  |
| slave_net_timeout | 3600  |
| slave_skip_errors | OFF   |
+-----+-----+
```

```
| slave_transaction_retries | 10 |
+-----+-----+
6 rows in set (0.00 sec)
```

The following information applies to all MySQL Cluster users.

16.10.7. Using Two Replication Channels

In a more complete example scenario, we envision two replication channels to provide redundancy and thereby guard against possible failure of a single replication channel. This requires a total of four replication servers, two masters for the master cluster and two slave servers for the slave cluster. For purposes of the discussion that follows, we assume that unique identifiers are assigned as shown here:

Server ID	Description
1	Master - primary replication channel (<i>M</i>)
2	Master - secondary replication channel (<i>M'</i>)
3	Slave - primary replication channel (<i>S</i>)
4	Slave - secondary replication channel (<i>S'</i>)

Setting up replication with two channels is not radically different from setting up a single replication channel. First, the `mysqld` processes for the primary and secondary replication masters must be started, followed by those for the primary and secondary slaves. Then the replication processes may be initiated by issuing the `START SLAVE` statement on each of the slaves. The commands and the order in which they need to be issued are shown here:

1. Start the primary replication master:

```
shellM> mysqld --ndbcluster --server-id=1 \
              --log-bin --binlog-format=row &
```

2. Start the secondary replication master:

```
shellM'> mysqld --ndbcluster --server-id=2 \
              --log-bin --binlog-format=row &
```

3. Start the primary replication slave server:

```
shellS> mysqld --ndbcluster --server-id=3 \
              --skip-slave-start &
```

4. Start the secondary replication slave:

```
shellS'> mysqld --ndbcluster --server-id=4 \
              --skip-slave-start &
```

5. Finally, initiate replication on the primary channel by executing the `START SLAVE` statement on the primary slave as shown here:

```
mysqlS> START SLAVE;
```

Warning

Only the primary channel is to be started at this point. The secondary replication channel is to be started only in the event that the primary replication channel fails, as described in [Section 16.10.8, “Implementing Failover with MySQL Cluster”](#). Running multiple replication channels simultaneously can result in unwanted duplicate records being created on the replication slaves.

As mentioned previously, it is not necessary to enable binary logging on replication slaves.

16.10.8. Implementing Failover with MySQL Cluster

In the event that the primary Cluster replication process fails, it is possible to switch over to the secondary replication channel. The fol-

lowing procedure describes the steps required to accomplish this.

1. Obtain the time of the most recent global checkpoint (GCP). That is, you need to determine the most recent epoch from the `ndb_apply_status` table on the slave cluster, which can be found using the following query:

```
mysqlS'> SELECT @latest:=MAX(epoch)
-> FROM mysql.ndb_apply_status;
```

2. Using the information obtained from the query shown in Step 1, obtain the corresponding records from the `ndb_binlog_index` table on the master cluster as shown here:

```
mysqlM'> SELECT
-> @file:=SUBSTRING_INDEX(File, '/', -1),
-> @pos:=Position
-> FROM mysql.ndb_binlog_index
-> WHERE epoch > @latest
-> ORDER BY epoch ASC LIMIT 1;
```

These are the records saved on the master since the failure of the primary replication channel. We have employed a user variable `@latest` here to represent the value obtained in Step 1. Of course, it is not possible for one `mysqld` instance to access user variables set on another server instance directly. These values must be “plugged in” to the second query manually or in application code.

3. Now it is possible to synchronize the secondary channel by running the following query on the secondary slave server:

```
mysqlS'> CHANGE MASTER TO
-> MASTER_LOG_FILE='@file',
-> MASTER_LOG_POS=@pos;
```

Again we have employed user variables (in this case `@file` and `@pos`) to represent the values obtained in Step 2 and applied in Step 3; in practice these values must be inserted manually or using application code that can access both of the servers involved.

Note

`@file` is a string value such as `'/var/log/mysql/replication-master-bin.00001'`, and so must be quoted when used in SQL or application code. However, the value represented by `@pos` must *not* be quoted. Although MySQL normally attempts to convert strings to numbers, this case is an exception.

4. You can now initiate replication on the secondary channel by issuing the appropriate command on the secondary slave `mysqld`:

```
mysqlS'> START SLAVE;
```

Once the secondary replication channel is active, you can investigate the failure of the primary and effect repairs. The precise actions required to do this will depend upon the reasons for which the primary channel failed.

Warning

The secondary replication channel is to be started only if and when the primary replication channel has failed. Running multiple replication channels simultaneously can result in unwanted duplicate records being created on the replication slaves.

If the failure is limited to a single server, it should (in theory) be possible to replicate from *M* to *S'*, or from *M'* to *S*; however, this has not yet been tested.

16.10.9. MySQL Cluster Backups With Replication

This section discusses making backups and restoring from them using MySQL Cluster replication. We assume that the replication servers have already been configured as covered previously (see [Section 16.10.5, “Preparing the Cluster for Replication”](#), and the sections immediately following). This having been done, the procedure for making a backup and then restoring from it is as follows:

1. There are two different methods by which the backup may be started.

- **Method A:**

This method requires that the cluster backup process was previously enabled on the master server, prior to starting the replication process. This can be done by including the line

```
ndb-connectstring=management_host[:port]
```

in a `[MYSQL_CLUSTER]` section in the `my.cnf` file, where *management_host* is the IP address or hostname of the NDB management server for the master cluster, and *port* is the management server's port number. Note that the port number needs to be specified only if the default port (1186) is not being used. (See [Section 16.3.3, “Multi-Computer Configuration”](#), for more information about ports and port allocation in MySQL Cluster.)

In this case, the backup can be started by executing this statement on the replication master:

```
shellM> ndb_mgm -e "START BACKUP"
```

- **Method B:**

If the `my.cnf` file does not specify where to find the management host, you can start the backup process by passing this information to the NDB management client as part of the `START BACKUP` command, like this:

```
shellM> ndb_mgm management_host:port -e "START BACKUP"
```

where *management_host* and *port* are the hostname and port number of the management server. In our scenario as outlined earlier (see [Section 16.10.5, “Preparing the Cluster for Replication”](#)), this would be executed as follows:

```
shellM> ndb_mgm rep-master:1186 -e "START BACKUP"
```

In either case, it is highly advisable to allow any pending transactions to be completed before beginning the backup, and then not to permit any new transactions to begin during the backup process.

2. Copy the cluster backup files to the slave that is being brought on line. Each system running an `ndbd` process for the master cluster will have cluster backup files located on it, and *all* of these files must be copied to the slave to ensure a successful restore. The backup files can be copied into any directory on the computer where the slave management host resides, so long as the MySQL and NDB binaries have read permissions in that directory. In this case, we will assume that these files have been copied into the directory `/var/BACKUPS/BACKUP-1`.

It is not necessary that the slave cluster have the same number of `ndbd` processes (data nodes) as the master; however, it is highly recommended this number be the same. It is necessary that the slave be started with the `--skip-slave-start` option, to prevent premature startup of the replication process.

3. Create any databases on the slave cluster that are present on the master cluster that are to be replicated to the slave.

Important

A `CREATE DATABASE` (or `CREATE SCHEMA`) statement corresponding to each database to be replicated must be executed on each SQL node in the slave cluster.

4. Reset the slave cluster using this statement in the MySQL Monitor:

```
mysqlS> RESET SLAVE;
```

It is important to make sure that the slave's `apply_status` table does not contain any records prior to running the restore process. You can accomplish this by running this SQL statement on the slave:

```
mysqlS> DELETE FROM mysql.ndb_apply_status;
```

5. You can now start the cluster restoration process on the replication slave using the `ndb_restore` command for each backup file in turn. For the first of these, it is necessary to include the `-m` option to restore the cluster metadata:

```
shellS> ndb_restore -c slave_host:port -n node-id \
-b backup-id -m -r dir
```

`dir` is the path to the directory where the backup files have been placed on the replication slave. For the `ndb_restore` commands corresponding to the remaining backup files, the `-m` option should *not* be used.

For restoring from a master cluster with four data nodes (as shown in the figure in [Section 16.10, “MySQL Cluster Replication”](#)) where the backup files have been copied to the directory `/var/BACKUPS/BACKUP-1`, the proper sequence of commands to be executed on the slave might look like this:

```
shellS> ndb_restore -c rep-slave:1186 -n 2 -b 1 -m \
-r ./var/BACKUPS/BACKUP-1
shellS> ndb_restore -c rep-slave:1186 -n 3 -b 1 \
-r ./var/BACKUPS/BACKUP-1
shellS> ndb_restore -c rep-slave:1186 -n 4 -b 1 \
-r ./var/BACKUPS/BACKUP-1
shellS> ndb_restore -c rep-slave:1186 -n 5 -b 1 -e \
-r ./var/BACKUPS/BACKUP-1
```

Important

The `-e` (or `--restore-epoch`) option in the final invocation of `ndb_restore` in this example is required in order that the epoch is written to the slave `mysql.ndb_apply_status`. Without this information, the slave will not be able to synchronize properly with the master. (See [Section 16.8.3, “ndb_restore — Restore a Cluster Backup”](#).)

- Now you need to obtain the most recent epoch from the `ndb_apply_status` table on the slave (as discussed in [Section 16.10.8, “Implementing Failover with MySQL Cluster”](#)):

```
mysqlS> SELECT @latest:=MAX(epoch)
FROM mysql.ndb_apply_status;
```

- Using `@latest` as the epoch value obtained in the previous step, you can obtain the correct starting position `@pos` in the correct binary log file `@file` from the master's `mysql.ndb_binlog_index` table using the query shown here:

```
mysqlM> SELECT
-> @file:=SUBSTRING_INDEX(File, '/', -1),
-> @pos:=Position
-> FROM mysql.ndb_binlog_index
-> WHERE epoch > @latest
-> ORDER BY epoch ASC LIMIT 1;
```

- Using the values obtained in the previous step, you can now issue the appropriate `CHANGE MASTER TO` statement in the slave's `mysql` client:

```
mysqlS> CHANGE MASTER TO
-> MASTER_LOG_FILE='@file',
-> MASTER_LOG_POS=@pos;
```

- Now that the slave “knows” from what point in which `binlog` file to start reading data from the master, you can cause the slave to begin replicating with this standard MySQL statement:

```
mysqlS> START SLAVE;
```

To perform a backup and restore on a second replication channel, it is necessary only to repeat these steps, substituting the hostnames and IDs of the secondary master and slave for those of the primary master and slave replication servers where appropriate, and running the preceding statements on them.

For additional information on performing Cluster backups and restoring Cluster from backups, see [Section 16.8, “On-line Backup of MySQL Cluster”](#).

16.10.9.1. Automating Synchronization of the Slave to the Master binlog

It is possible to automate much of the process described in the previous section (see [Section 16.10.9, “MySQL Cluster Backups With Replication”](#)). The following Perl script `reset-slave.pl` serves as an example of how you can do this.

```
#!/user/bin/perl -w
# file: reset-slave.pl

16.10.10. MySQL Cluster Replication Conflict Resolution

MySQL Cluster 5.1 Carrier Grade Edition

The information in this section applies to users of MySQL Cluster 5.1 Carrier Grade Edition only. For more information about MySQL Cluster 5.1 Carrier Grade Edition, see Section 16.2, “MySQL Cluster 5.1 Carrier Grade Edition”.

When using a replication setup involving multiple masters, it is possible that different masters may try to update the same row on the slave with different data. Conflict resolution in MySQL Cluster Replication provides a means of resolving such conflicts by allowing a user defined “timestamp” column to be used to determine whether or not an update to the row on a given master should be applied on the slave. Generally speaking, if the “timestamp” for a given row coming from the master is higher than that on the slave, it is applied it; otherwise it is not applied on the slave.

It is available in MySQL Cluster 5.1 Carrier Grade Edition releases beginning with MySQL 5.1.19-ndb-6.3.0.

This replication scheme, also known as “changed parameter only replication”, is configurable on a per-table basis.

- On the master, it must be determined which columns to send (all columns or only those that have been updated).
- On the slave, it must be determined which type of conflict resolution to apply (none or “latest timestamp wins”).

If only some but not all columns are sent, then the master and slave can diverge.

Note

We refer to the column used for determining updates as a “timestamp” column, but the data type of this column is never **TIMESTAMP**; rather, its data type can be either of **INT SIGNED** or **INT UNSIGNED**.

We can see update operations in terms of “before” and “after” images — that is, the states of the table before and after the update is applied. Normally, when updating a table with a primary key, the “before” image is not of great interest; however, when we need to determine on a per-update basis whether or not to use the updated values on a replication slave, we need to make sure that both images are written to the master's binary log. This is done with the **--ndb-log-update-as-write** startup option for **mysqld**, as described later in this section.

Whether logging of complete rows or of updated columns only is done is decided when the MySQL server is started, and cannot be changed online; you must either restart **mysqld**, or start a new **mysqld** instance with different logging options.

For purposes of conflict resolution, there are two basic methods of logging rows:

- Log complete rows
- Log only column data that has been updated — that is, column data whose value has been set, regardless of whether or not this value was actually changed.

Either of the above logging methods can be configured to be done with or without the “before” image.

mysqld startup options. The following **mysqld** startup options are available to control conflict resolution:

- **--ndb-log-update-as-write**. Because conflict resolution is done in the MySQL Server's update handler, it is necessary to control logging on the master such that updates are updates and not writes as in in mainline MySQL 5.1. This option is turned on by default; to turn it off, start the server with **--ndb-log-update-as-write=0** or **--ndb-log-update-as-write=OFF**.
- **--ndb-log-updated-only**. In general it is preferable to log full rows. However, depending on the application, it may be sufficient to log only the updates, and can be more efficient to do so. This can be done by setting **--ndb-log-updated-only** to **1** or **ON**.

To enable conflict resolution, it is necessary to create an **ndb_replication** table in the **mysql** system database on the master, the slave, or both, depending on the conflict resolution type and method to be employed. This table is used in order to control logging and conflict resolution function on a per-table basis, and has one row per table involved in replication. Each row in **mysql.ndb_replication** corresponding to a given table specifies how to log and resolve conflicts for that table. The definition of this table is shown here:

```
CREATE TABLE mysql.ndb_replication (
  db VARBINARY(63),
  table_name VARBINARY(63),
```

```

server_id INT UNSIGNED,
binlog_type INT UNSIGNED,
conflict_fn VARBINARY(128),
PRIMARY KEY USING HASH (db, table_name, server_id)
)
ENGINE=NDB
PARTITION BY KEY(db, table_name);

```

The columns in this table are described in the following list:

- **db**. The name of the database containing the table to be replicated.
- **table_name**. The name of the table to be replicated.
- **server_id**. The unique server ID of the MySQL instance (SQL node) where the table resides.
- **binlog_type**. The type of binary logging to be employed. This is determined as shown in the following table:

Value	Internal Value	Description
0	NBT_DEFAULT	Use server default
1	NBT_NO_LOGGING	Do not log this table in the binary log
2	NBT_UPDATED_ONLY	Only updated attributes are logged
3	NBT_FULL	Log full row, even if not updated (MySQL server default behavior)
4	NBT_USE_UPDATE	(For generating NBT_UPDATED_ONLY_USE_UPDATE and NBT_FULL_USE_UPDATE values only — not intended for separate use)
5	[Not used]	---
6	NBT_UPDATED_ONLY_USE_UPDATE (= NBT_UPDATED_ONLY NBT_USE_UPDATE)	Use updated attributes, even if values are unchanged
7	NBT_FULL_USE_UPDATE(= NBT_FULL NBT_USE_UPDATE)	Use full row, even if values are unchanged

- **conflict_fn**. The conflict resolution function to be applied. Currently this function must be specified as either `NDB$MAX(column_name)` or `NULL` (if conflict resolution is not to be used).

Important

The `mysql.ndb_replication` table is read when the table is set up for replication, so the row corresponding to a table to be replicated must be inserted into `mysql.ndb_replication` *before* creation of the table to be replicated takes place.

Example. Suppose you wish to enable conflict resolution on table `test.t1`, using column `mycol` as the “timestamp”. This can be done using the following two steps:

- On the master, perform this query:

```

INSERT INTO mysql.ndb_replication VALUES
("test", "t1", 0, NULL, "NDB$MAX(mycol)");

```

Inserting a 0 into the `server_id` indicates that all SQL nodes accessing this table should use the conflict resolution. If you want to use conflict resolution on a specific `mysqld` only, use the actual server ID.

Inserting `NULL` into the `binlog_type` column has the same effect as inserting 0 (`NBT_DEFAULT`); the server default is used.

- Create the `test.t1` table:

```

CREATE TABLE test.t1 (
  columns
  mycol INT UNSIGNED,
  columns

```

```
);
```

Now, when updates are done on this table, conflict resolution will be applied, and the version of the row having the greatest value for `mycol` will be written to the slave.

16.11. MySQL Cluster Disk Data Tables

Beginning with MySQL 5.1.6, it is possible to store the non-indexed columns of `NDB` tables on disk, rather than in RAM as with previous versions of MySQL Cluster.

As part of implementing Cluster Disk Data work, a number of improvements were made in MySQL Cluster for the efficient handling of very large amounts (terabytes) of data during node recovery and restart. These include a “no-steal” algorithm for synchronising a starting node with very large data sets. For more information, see the paper [Recovery Principles of MySQL Cluster 5.1](#), by MySQL Cluster developers Mikael Ronström and Jonas Öreland.

16.11.1. Disk Data Objects

This section discusses Disk Data objects — which include tables, log file groups, and tablespaces — as well as how to create and drop them.

Assuming that you have already set up a MySQL Cluster with all nodes (including management and SQL nodes) running MySQL 5.1.6 or newer, the basic steps for creating a Cluster table on disk are as follows:

1. Create a *log file group*, and assign one or more undo log files to it (an undo log file is also referred to as an *undofile*).

Note

In MySQL 5.1, undo log files are necessary only for Disk Data tables. They are no longer used for tables that are stored in memory.

2. Create a *tablespace*, and assign the log file group to it, as well as one or more data files.
3. Create a Disk Data table that uses this tablespace for data storage.

Each of these tasks can be accomplished using SQL statements, as shown in the following example.

1. We create a log file group named `lg_1` using `CREATE LOGFILE GROUP`. This log file group is to be made up of two undo log files, which we name `undo_1.dat` and `undo_2.dat`, whose initial sizes are 16 MB and 12 MB, respectively. (The default initial size for an undo log file is 128 MB.) Optionally, you can also specify a size for the log file group's `UNDO` buffer, or allow it to assume the default value of 8 MB. In this example, we set the `UNDO` buffer's size at 2 MB. A log file group must be created with an undo log file; so we add `undo_1.dat` to `lg_1` in this `CREATE LOGFILE GROUP` statement:

```
CREATE LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_1.dat'
  INITIAL_SIZE 16M
  UNDO_BUFFER_SIZE 2M
  ENGINE NDB;
```

To add `undo_2.dat` to the log file group, use the following `ALTER LOGFILE GROUP` statement:

```
ALTER LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_2.dat'
  INITIAL_SIZE 12M
  ENGINE NDB;
```

Some items of note:

- The `.dat` file extension used here is not required. We use it merely to make the log and data files easily recognisable.
- Every `CREATE LOGFILE GROUP` and `ALTER LOGFILE GROUP` statement must include an `ENGINE` clause. In MySQL 5.1, the permitted values for this clause are `NDB` and `NDBCLUSTER`.

Important

In MySQL 5.1.8 and later, there can exist only one log file group at any given time.

- When you add an undo log file to a log file group using `ADD UNDOFILE 'filename'`, a file with the name *filename* is created in the `ndb_nodeid_fs` directory within the `DataDirectory` of each data node in the cluster, where *nodeid* is the node ID of the data node.
- `UNDO_BUFFER_SIZE` is limited by the amount of system memory available.
- For more information about the `CREATE LOGFILE GROUP` statement, see [Section 12.1.8, “CREATE LOGFILE GROUP Syntax”](#). For more information about `ALTER LOGFILE GROUP`, see [Section 12.1.2, “ALTER LOGFILE GROUP Syntax”](#).

2.

Now we can create a tablespace, which contains files to be used by MySQL Cluster Disk Data tables for storing their data. A tablespace is also associated with a particular log file group. When creating a new tablespace, you must specify the log file group which it is to use for undo logging; you must also specify a data file. You can add more data files to the tablespace after the tablespace is created; it is also possible to drop data files from a tablespace (an example of dropping data files is provided later in this section).

Assume that we wish to create a tablespace named `ts_1` which uses `lg_1` as its log file group. This tablespace is to contain two data files named `data_1.dat` and `data_2.dat`, whose initial sizes are 32 MB and 48 MB, respectively. (The default value for `INITIAL_SIZE` is 128 MB.) We can do this using two SQL statements, as shown here:

```
CREATE TABLESPACE ts_1
  ADD DATAFILE 'data_1.dat'
  USE LOGFILE GROUP lg_1
  INITIAL_SIZE 32M
  ENGINE NDB;

ALTER TABLESPACE ts_1
  ADD DATAFILE 'data_2.dat'
  INITIAL_SIZE 48M
  ENGINE NDB;
```

The `CREATE TABLESPACE` statement creates a tablespace `ts_1` with the data file `data_1.dat`, and associates `ts_1` with log file group `lg_1`. The `ALTER TABLESPACE` adds the second data file (`data_2.dat`).

Some items of note:

- As is the case with the filenames used here for undo log files, there is no special significance for the `.dat` file extension; it is used merely for easy recognition.
- All `CREATE TABLESPACE` and `ALTER TABLESPACE` statements must contain an `ENGINE` clause; only tables using the same storage engine as the tablespace can be created in the tablespace. In MySQL 5.1, the only permitted values for this clause are `NDB` and `NDBCLUSTER`.

For more information about the `CREATE TABLESPACE` and `ALTER TABLESPACE` statements, see [Section 12.1.11, “CREATE TABLESPACE Syntax”](#), and [Section 12.1.5, “ALTER TABLESPACE Syntax”](#).

3.

Now it is possible to create a table whose non-indexed columns are stored on disk in the tablespace `ts_1`:

```
CREATE TABLE dt_1 (
  member_id INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
  last_name VARCHAR(50) NOT NULL,
  first_name VARCHAR(50) NOT NULL,
  dob DATE NOT NULL,
  joined DATE NOT NULL,
  INDEX(last_name, first_name)
)
TABLESPACE ts_1 STORAGE DISK
ENGINE NDB;
```

The `TABLESPACE ... STORAGE DISK` clause tells the `NDB Cluster` storage engine to use tablespace `ts_1` for disk data storage.

Note

MySQL Cluster 5.1 Carrier Grade Edition

The following information applies to users of MySQL Cluster 5.1 Carrier Grade Edition only. For more information about MySQL Cluster 5.1 Carrier Grade Edition, see Section 16.2, “MySQL Cluster 5.1 Carrier Grade Edition”.

Beginning with MySQL 5.1.19-ndb-6.2.5 and MySQL 5.1.20-ndb-6.3.2, it is also possible to specify whether an individual column is stored on disk or in memory by using a **STORAGE** clause as part of the column's definition in a **CREATE TABLE** or **ALTER TABLE** statement. **STORAGE DISK** causes the column to be stored on disk, and **STORAGE MEMORY** causes in-memory storage to be used. See Section 12.1.10, “**CREATE TABLE Syntax**”, for more information.

The following information applies to all MySQL Cluster users.

Once table `ts_1` has been created as shown, you can perform **INSERT**, **SELECT**, **UPDATE**, and **DELETE** statements on it just as you would with any other MySQL table.

For table `dt_1` as it has been defined here, only the `dob` and `joined` columns are stored on disk. This is because there are indexes on the `id`, `last_name`, and `first_name` columns, and so data belonging to these columns is stored in RAM. In MySQL 5.1, only non-indexed columns can be held on disk; indexes and indexed column data continue to be stored in memory. This trade-off between the use of indexes and conservation of RAM is something you must keep in mind as you design Disk Data tables.

Performance note. The performance of a cluster using Disk Data storage is greatly improved if Disk Data files are kept on a separate physical disk from the data node filesystem. This must be done for each data node in the cluster to derive any noticeable benefit.

You may use absolute and relative filesystem paths with **ADD UNDOFILE** and **ADD DATAFILE**. Relative paths are calculated relative to the data node's data directory.

A log file group, a tablespace, and any Disk Data tables using these must be created in a particular order. The same is true for dropping any of these objects:

- A log file group cannot be dropped, so long as any tablespaces are using it.
- A tablespace cannot be dropped as long as it contains any data files.
- You cannot drop any data files from a tablespace as long as there remain any tables which are using the tablespace.
- Beginning with MySQL 5.1.12, it is no longer possible to drop files created in association with a different tablespace than the one with which the files were created. ([Bug#20053](#))

For example, to drop all the objects created so far in this section, you would use the following statements:

```
mysql> DROP TABLE dt_1;

mysql> ALTER TABLESPACE ts_1
-> DROP DATAFILE 'data_2.dat'
-> ENGINE NDB;

mysql> ALTER TABLESPACE ts_1
-> DROP DATAFILE 'data_1.dat'
-> ENGINE NDB;

mysql> DROP TABLESPACE ts_1
-> ENGINE NDB;

mysql> DROP LOGFILE GROUP lg_1
-> ENGINE NDB;
```

These statements must be performed in the order shown, except that the two **ALTER TABLESPACE ... DROP DATAFILE** statements may be executed in either order.

You can obtain information about data files used by Disk Data tables by querying the **FILES** table in the **INFORMATION_SCHEMA** database. An extra “**NULL** row” was added to this table in MySQL 5.1.14 for providing additional information about undo log files. For more information and examples of use, see Section 23.21, “**The INFORMATION_SCHEMA FILES Table**”.

16.11.2. Disk Data Storage Requirements

The following items apply to Disk Data storage requirements:

- Variable-length columns of Disk Data tables take up a fixed amount of space. For each row, this is equal to the space required to store the largest possible value for that column.

For general information about calculating these values, see [Section 10.5, “Data Type Storage Requirements”](#).

- In a Disk Data table, the first 256 bytes of a [TEXT](#) or [BLOB](#) column are stored in memory; only the remainder is stored on disk.

Important

Starting the cluster with the `--initial` option does *not* remove Disk Data files. You must remove these manually prior to performing an initial restart of the cluster.

16.11.3. Disk Data Configuration Parameters

Configuration parameters affecting Disk Data behaviour include the following:

- [DiskPageBufferMemory](#)

This determines the amount of space used for caching pages on disk, and is set in the `[NDBD]` or `[NDBD DEFAULT]` section of the `config.ini` file. It is measured in bytes. Each page takes up 32 KB. This means that Cluster Disk Data storage always uses $N * 32$ KB memory where N is some non-negative integer.

- [SharedGlobalMemory](#)

This determines the amount of memory that is used for log buffers, disk operations (such as page requests and wait queues), and metadata for tablespaces, log file groups, [UNDO](#) files, and data files. It can be set in the `[NDBD]` or `[NDBD DEFAULT]` section of the `config.ini` configuration file, and is measured in bytes.

The default value is `20M`.

Note

The `OPTIMIZE TABLE` statement does not have any effect on Disk Data tables.

16.12. Using High-Speed Interconnects with MySQL Cluster

Even before design of [NDB Cluster](#) began in 1996, it was evident that one of the major problems to be encountered in building parallel databases would be communication between the nodes in the network. For this reason, [NDB Cluster](#) was designed from the very beginning to allow for the use of a number of different data transport mechanisms. In this Manual, we use the term *transporter* for these.

The MySQL Cluster codebase includes support for four different transporters:

- *TCP/IP using 100 Mbps or gigabit Ethernet*, as discussed in [Section 16.4.4.7, “Cluster TCP/IP Connections”](#).
- *Direct (machine-to-machine) TCP/IP*; although this transporter uses the same TCP/IP protocol as mentioned in the previous item, it requires setting up the hardware differently and is configured differently as well. For this reason, it is considered a separate transport mechanism for MySQL Cluster. See [Section 16.4.4.8, “TCP/IP Connections Using Direct Connections”](#), for details.
- *Shared memory (SHM)*. For more information about SHM, see [Section 16.4.4.9, “Shared-Memory Connections”](#).
- *Scalable Coherent Interface (SCI)*, as described in the next section of this chapter, [Section 16.4.4.10, “SCI Transport Connections”](#).

Most users today employ TCP/IP over Ethernet because it is ubiquitous. TCP/IP is also by far the best-tested transporter for use with MySQL Cluster.

We are working to make sure that communication with the `ndbd` process is made in “chunks” that are as large as possible because this benefits all types of data transmission.

For users who desire it, it is also possible to use cluster interconnects to enhance performance even further. There are two ways to achieve this: Either a custom transporter can be designed to handle this case, or you can use socket implementations that bypass the TCP/IP stack to one extent or another. We have experimented with both of these techniques using the SCI (Scalable Coherent Interface) technology developed by [Dolphin](#).

16.12.1. Configuring MySQL Cluster to use SCI Sockets

In this section, we show how to adapt a cluster configured for normal TCP/IP communication to use SCI Sockets instead. This documentation is based on SCI Sockets version 2.3.0 as of 01 October 2004.

Prerequisites. Any machines with which you wish to use SCI Sockets must be equipped with SCI cards.

No special builds (other than the `-max` builds) are needed for SCI Sockets because it uses normal TCP/IP socket calls which are already available in MySQL Cluster. However, SCI Sockets are currently supported only on the Linux 2.4 and 2.6 kernels. For other operating systems, you can use SCI Transporters, but this requires that the server be built using `--with-ndb-sci=/opt/DIS`.

Prior to MySQL 5.1.20, there were issues with building MySQL Cluster with SCI support (see [Bug#25470](#)), but these have been resolved due to work contributed by Dolphin International. SCI Sockets are now correctly supported for MySQL Cluster using the `-max` builds, and versions of MySQL Cluster with SCI Transporter support can be built using either of `compile-amd64-max-sci` or `compile-pentium64-max-sci`. Both of these build scripts can be found in the `BUILD` directory of the MySQL 5.1 source; it should not be difficult to adapt them for other platforms.

There are essentially four requirements for SCI Sockets:

- Building the SCI Socket libraries.
- Installation of the SCI Socket kernel libraries.
- Installation of one or two configuration files.
- The SCI Socket kernel library must be enabled either for the entire machine or for the shell where the MySQL Cluster processes are started.

This process needs to be repeated for each machine in the cluster where you plan to use SCI Sockets for inter-node communication.

Two packages need to be retrieved to get SCI Sockets working:

- The source code package containing the DIS support libraries for the SCI Sockets libraries.
- The source code package for the SCI Socket libraries themselves.

Currently, these are available only in source code format. The latest versions of these packages at the time of this writing were available as (respectively) `DIS_GPL_2_5_0_SEP_10_2004.tar.gz` and `SCI_SOCKET_2_3_0_OKT_01_2004.tar.gz`. You should be able to find these (or possibly newer versions) at <http://www.dolphinics.no/support/downloads.html>.

Package Installation. Once you have obtained the library packages, the next step is to unpack them into appropriate directories, with the SCI Sockets library unpacked into a directory below the DIS code. Next, you need to build the libraries. This example shows the commands used on Linux/x86 to perform this task:

```
shell> tar xzf DIS_GPL_2_5_0_SEP_10_2004.tar.gz
shell> cd DIS_GPL_2_5_0_SEP_10_2004/src/
shell> tar xzf ../../SCI_SOCKET_2_3_0_OKT_01_2004.tar.gz
shell> cd ../adm/bin/Linux_pkgs
shell> ./make_PSB_66_release
```

It is possible to build these libraries for some 64-bit processors. To build the libraries for Opteron CPUs using the 64-bit extensions, run `make_PSB_66_X86_64_release` rather than `make_PSB_66_release`. If the build is made on an Itanium machine, you should use `make_PSB_66_IA64_release`. The X86-64 variant should work for Intel EM64T architectures but this has not yet (to our knowledge) been tested.

Once the build process is complete, the compiled libraries will be found in a zipped tar file with a name along the lines of `DIS-<operating-system>-time-date`. It is now time to install the package in the proper place. In this example we will place the installation in `/opt/DIS`. You most likely need to run the following as the system `root` user.

```
shell> cp DIS_Linux_2.4.20-8_181004.tar.gz /opt/
shell> cd /opt
shell> tar xzf DIS_Linux_2.4.20-8_181004.tar.gz
shell> mv DIS_Linux_2.4.20-8_181004 DIS
```

Network configuration. Now that all the libraries and binaries are in their proper place, we need to ensure that the SCI cards have proper node IDs within the SCI address space.

It is also necessary to decide on the network structure before proceeding. There are three types of network structures which can be used in this context:

- A simple one-dimensional ring
- One or more SCI switches with one ring per switch port
- A two- or three-dimensional torus.

Each of these topologies has its own method for providing node IDs. We discuss each of them in brief.

A simple ring uses node IDs which are non-zero multiples of 4: 4, 8, 12,...

The next possibility uses SCI switches. An SCI switch has 8 ports, each of which can support a ring. It is necessary to make sure that different rings use different node ID spaces. In a typical configuration, the first port uses node IDs below 64 (4 – 60), the next 64 node IDs (68 – 124) are assigned to the next port, and so on, with node IDs 452 – 508 being assigned to the eighth port.

Two- and three-dimensional torus network structures take into account where each node is located in each dimension, incrementing by 4 for each node in the first dimension, by 64 in the second dimension, and (where applicable) by 1024 in the third dimension. See [Dolphin's Web site](#) for more thorough documentation.

In our testing we have used switches, although most large cluster installations use 2- or 3-dimensional torus structures. The advantage provided by switches is that, with dual SCI cards and dual switches, it is possible to build with relative ease a redundant network where the average failover time on the SCI network is on the order of 100 microseconds. This is supported by the SCI transporter in MySQL Cluster and is also under development for the SCI Socket implementation.

Failover for the 2D/3D torus is also possible but requires sending out new routing indexes to all nodes. However, this requires only 100 milliseconds or so to complete and should be acceptable for most high-availability cases.

By placing cluster data nodes properly within the switched architecture, it is possible to use 2 switches to build a structure whereby 16 computers can be interconnected and no single failure can hinder more than one of them. With 32 computers and 2 switches it is possible to configure the cluster in such a manner that no single failure can cause the loss of more than two nodes; in this case, it is also possible to know which pair of nodes is affected. Thus, by placing the two nodes in separate node groups, it is possible to build a “safe” MySQL Cluster installation.

To set the node ID for an SCI card use the following command in the `/opt/DIS/sbin` directory. In this example, `-c 1` refers to the number of the SCI card (this is always 1 if there is only 1 card in the machine); `-a 0` refers to adapter 0; and `68` is the node ID:

```
shell> ./sciconfig -c 1 -a 0 -n 68
```

If you have multiple SCI cards in the same machine, you can determine which card has which slot by issuing the following command (again we assume that the current working directory is `/opt/DIS/sbin`):

```
shell> ./sciconfig -c 1 -gsn
```

This will give you the SCI card's serial number. Then repeat this procedure with `-c 2`, and so on, for each card in the machine. Once you have matched each card with a slot, you can set node IDs for all cards.

After the necessary libraries and binaries are installed, and the SCI node IDs are set, the next step is to set up the mapping from host-names (or IP addresses) to SCI node IDs. This is done in the SCI sockets configuration file, which should be saved as `/etc/sci/scisock.conf`. In this file, each SCI node ID is mapped through the proper SCI card to the hostname or IP address that it

is to communicate with. Here is a very simple example of such a configuration file:

```
#host      #nodeId
alpha      8
beta       12
192.168.10.20 16
```

It is also possible to limit the configuration so that it applies only to a subset of the available ports for these hosts. An additional configuration file `/etc/sci/scisock_opt.conf` can be used to accomplish this, as shown here:

```
# -key          -type          -values
EnablePortsByDefault  yes
EnablePort            tcp          2200
DisablePort           tcp          2201
EnablePortRange       tcp          2202 2219
DisablePortRange      tcp          2220 2231
```

Driver installation. With the configuration files in place, the drivers can be installed.

First, the low-level drivers and then the SCI socket driver need to be installed:

```
shell> cd DIS/sbin/
shell> ./drv-install add PSB66
shell> ./scisocket-install add
```

If desired, the installation can be checked by invoking a script which verifies that all nodes in the SCI socket configuration files are accessible:

```
shell> cd /opt/DIS/sbin/
shell> ./status.sh
```

If you discover an error and need to change the SCI socket configuration, it is necessary to use `ksocketconfig` to accomplish this task:

```
shell> cd /opt/DIS/util
shell> ./ksocketconfig -f
```

Testing the setup. To ensure that SCI sockets are actually being used, you can employ the `latency_bench` test program. Using this utility's server component, clients can connect to the server to test the latency of the connection. Determining whether SCI is enabled should be fairly simple from observing the latency.

Note

Before using `latency_bench`, it is necessary to set the `LD_PRELOAD` environment variable as shown later in this section.

To set up a server, use the following:

```
shell> cd /opt/DIS/bin/socket
shell> ./latency_bench -server
```

To run a client, use `latency_bench` again, except this time with the `-client` option:

```
shell> cd /opt/DIS/bin/socket
shell> ./latency_bench -client server_hostname
```

SCI socket configuration should now be complete and MySQL Cluster ready to use both SCI Sockets and the SCI transporter (see [Section 16.4.4.10, “SCI Transport Connections”](#)).

Starting the cluster. The next step in the process is to start MySQL Cluster. To enable usage of SCI Sockets it is necessary to set the environment variable `LD_PRELOAD` before starting `ndbd`, `mysqld`, and `ndb_mgmd`. This variable should point to the kernel library for SCI Sockets.

To start `ndbd` in a bash shell, do the following:

```
bash-shell> export LD_PRELOAD=/opt/DIS/lib/libkscisock.so
bash-shell> ndbd
```

In a tcsh environment the same thing can be accomplished with:

```
tcsh-shell> setenv LD_PRELOAD=/opt/DIS/lib/libkscisock.so
tcsh-shell> ndbd
```

Note

MySQL Cluster can use only the kernel variant of SCI Sockets.

16.12.2. Understanding the Impact of Cluster Interconnects

The `ndbd` process has a number of simple constructs which are used to access the data in a MySQL Cluster. We have created a very simple benchmark to check the performance of each of these and the effects which various interconnects have on their performance.

There are four access methods:

- **Primary key access.** This is access of a record through its primary key. In the simplest case, only one record is accessed at a time, which means that the full cost of setting up a number of TCP/IP messages and a number of costs for context switching are borne by this single request. In the case where multiple primary key accesses are sent in one batch, those accesses share the cost of setting up the necessary TCP/IP messages and context switches. If the TCP/IP messages are for different destinations, additional TCP/IP messages need to be set up.
- **Unique key access.** Unique key accesses are similar to primary key accesses, except that a unique key access is executed as a read on an index table followed by a primary key access on the table. However, only one request is sent from the MySQL Server, and the read of the index table is handled by `ndbd`. Such requests also benefit from batching.
- **Full table scan.** When no indexes exist for a lookup on a table, a full table scan is performed. This is sent as a single request to the `ndbd` process, which then divides the table scan into a set of parallel scans on all cluster `ndbd` processes. In future versions of MySQL Cluster, an SQL node will be able to filter some of these scans.

- **Range scan using ordered index**

When an ordered index is used, it performs a scan in the same manner as the full table scan, except that it scans only those records which are in the range used by the query transmitted by the MySQL server (SQL node). All partitions are scanned in parallel when all bound index attributes include all attributes in the partitioning key.

To check the base performance of these access methods, we have developed a set of benchmarks. One such benchmark, `testReadPerf`, tests simple and batched primary and unique key accesses. This benchmark also measures the setup cost of range scans by issuing scans returning a single record. There is also a variant of this benchmark which uses a range scan to fetch a batch of records.

In this way, we can determine the cost of both a single key access and a single record scan access, as well as measure the impact of the communication media used, on base access methods.

In our tests, we ran the base benchmarks for both a normal transporter using TCP/IP sockets and a similar setup using SCI sockets. The figures reported in the following table are for small accesses of 20 records per access. The difference between serial and batched access decreases by a factor of 3 to 4 when using 2KB records instead. SCI Sockets were not tested with 2KB records. Tests were performed on a cluster with 2 data nodes running on 2 dual-CPU machines equipped with AMD MP1900+ processors.

Access Type	TCP/IP Sockets	SCI Socket
Serial pk access	400 microseconds	160 microseconds
Batched pk access	28 microseconds	22 microseconds
Serial uk access	500 microseconds	250 microseconds
Batched uk access	70 microseconds	36 microseconds
Indexed eq-bound	1250 microseconds	750 microseconds
Index range	24 microseconds	12 microseconds

We also performed another set of tests to check the performance of SCI Sockets *vis-à-vis* that of the SCI transporter, and both of these as compared with the TCP/IP transporter. All these tests used primary key accesses either serially and multi-threaded, or multi-threaded and batched.

The tests showed that SCI sockets were about 100% faster than TCP/IP. The SCI transporter was faster in most cases compared to SCI sockets. One notable case occurred with many threads in the test program, which showed that the SCI transporter did not perform very well when used for the `mysqld` process.

Our overall conclusion was that, for most benchmarks, using SCI sockets improves performance by approximately 100% over TCP/IP, except in rare instances when communication performance is not an issue. This can occur when scan filters make up most of processing time or when very large batches of primary key accesses are achieved. In that case, the CPU processing in the `ndbd` processes becomes a fairly large part of the overhead.

Using the SCI transporter instead of SCI Sockets is only of interest in communicating between `ndbd` processes. Using the SCI transporter is also only of interest if a CPU can be dedicated to the `ndbd` process because the SCI transporter ensures that this process will never go to sleep. It is also important to ensure that the `ndbd` process priority is set in such a way that the process does not lose priority due to running for an extended period of time, as can be done by locking processes to CPUs in Linux 2.6. If such a configuration is possible, the `ndbd` process will benefit by 10–70% as compared with using SCI sockets. (The larger figures will be seen when performing updates and probably on parallel scan operations as well.)

There are several other optimized socket implementations for computer clusters, including Myrinet, Gigabit Ethernet, Infiniband and the VIA interface. We have tested MySQL Cluster so far only with SCI sockets. See [Section 16.12.1, “Configuring MySQL Cluster to use SCI Sockets”](#) for information on how to set up SCI sockets using ordinary TCP/IP for MySQL Cluster.

16.13. Known Limitations of MySQL Cluster

In the sections that follow, we discuss known limitations in MySQL 5.1 Cluster and MySQL Cluster 5.1 Carrier Grade Edition releases as compared with the features available when using the `MyISAM` and `InnoDB` storage engines. Currently, there are no plans to address these in coming releases of MySQL 5.1 or MySQL Cluster 5.1 Carrier Grade Edition; however, we will attempt to supply fixes for these issues in subsequent release series. If you check the “Cluster” category in the MySQL bugs database at <http://bugs.mysql.com>, you can find known bugs which (if marked “5.1”) we intend to correct in upcoming releases of MySQL 5.1. Some of these issues may be addressed in MySQL Cluster 5.1 Carrier Grade Edition and the fixes included in a future mainline MySQL Cluster version.

This information is intended to be complete with respect to the conditions just set forth. You can report any discrepancies that you encounter to the MySQL bugs database using the instructions given in [Section 1.8, “How to Report Bugs or Problems”](#). If we do not plan to fix the problem in MySQL 5.1, we will add it to the list.

See [Section 16.13.11, “Previous MySQL Cluster Issues Resolved in MySQL 5.1”](#) for a list of issues in MySQL Cluster in MySQL 5.0 that have been resolved in the current version.

Note

Limitations and other issues specific to MySQL Cluster Replication are described in [Section 16.10.3, “Known Issues in MySQL Cluster Replication”](#).

16.13.1. Non-Compliance In SQL Syntax

Some SQL statements relating to certain MySQL features produce errors when used with `NDB` tables, as described in the following list:

- **Temporary tables.** Temporary tables are not supported. Trying either to create a temporary table that uses the `NDB` storage engine or to alter an existing temporary table to use `NDB` fails with the error `TABLE STORAGE ENGINE 'NDBCLUSTER' DOES NOT SUPPORT THE CREATE OPTION 'TEMPORARY'`.
- **Indexes and keys in `NDB` tables.** Keys and indexes on MySQL Cluster tables are subject to the following limitations:
 - **TEXT and BLOB columns.** You cannot create indexes on `NDB` table columns that use any of the `TEXT` or `BLOB` data types.
 - **FULLTEXT indexes.** The `NDB` storage engine does not support `FULLTEXT` indexes, which are possible for `MyISAM` tables only.

However, you can create indexes on `VARCHAR` columns of `NDB` tables.

- **BIT columns.** A `BIT` column cannot be a primary key, unique key, or index, nor can it be part of a composite primary key, unique key, or index.
- **AUTO_INCREMENT columns.** Like other MySQL storage engines, the `NDB` storage engine can handle a maximum of one `AUTO_INCREMENT` column per table. However, in the case of a Cluster table with no explicit primary key, an

`AUTO_INCREMENT` column is automatically defined and used as a “hidden” primary key. For this reason, you cannot define a table that has an explicit `AUTO_INCREMENT` column unless that column is also declared using the `PRIMARY KEY` option. Attempting to create a table with an `AUTO_INCREMENT` column that is not the table's primary key, and using the `NDB` storage engine, fails with an error.

- **MySQL Cluster and geometry data types.** Geometry datatypes (`WKT` and `WKB`) are supported in `NDB` tables in MySQL 5.1. However, spatial indexes are not supported.
- **Creating `NDB` tables with user-defined partitioning.** Support for user-defined partitioning for MySQL Cluster in MySQL 5.1 is restricted to `[LINEAR] KEY` partitioning. Beginning with MySQL 5.1.12, using any other partitioning type with `ENGINE=NDB` or `ENGINE=NDBCLUSTER` in a `CREATE TABLE` statement results in an error.
- **Default partitioning scheme.** As of MySQL 5.1.6, all Cluster tables are by default partitioned by `KEY` using the table's primary key as the partitioning key. If no primary key is explicitly set for the table, the “hidden” primary key automatically created by the `NDB` storage engine is used instead. For additional discussion of these and related issues, see [Section 17.2.4, “KEY Partitioning”](#).
- **`DROP PARTITION` not supported.** It is not possible to drop partitions from `NDB` tables using `ALTER TABLE ... DROP PARTITION`. The other partitioning extensions to `ALTER TABLE` — `ADD PARTITION`, `REORGANIZE PARTITION`, and `COALESCE PARTITION` — are supported for Cluster tables, but use copying and so are not optimised. See [Section 17.3.1, “Management of RANGE and LIST Partitions”](#) and [Section 12.1.4, “ALTER TABLE Syntax”](#).
- **Row-based replication.** When using row-based replication with MySQL Cluster, binary logging cannot be disabled. That is, the `NDB` storage engine ignores the value of `SQL_LOG_BIN`. (Bug#16680)

16.13.2. Limits and Differences from Standard MySQL Limits

In this section, we list limits found in MySQL Cluster that either differ from limits found in, or that are not found in, standard MySQL.

- **Memory usage and recovery.** Memory consumed when data is inserted into an `NDB` table is not automatically recovered when deleted, as it is with other storage engines. Instead, the following rules hold true:
 - A `DELETE` statement on an `NDB` table makes the memory formerly used by the deleted rows available for re-use by inserts on the same table only. This memory cannot be used by other `NDB` tables.
 - A `DROP TABLE` or `TRUNCATE` operation on an `NDB` table frees the memory that was used by this table for re-use by any `NDB` table, either by the same table or by another `NDB` table.

Note

Recall that `TRUNCATE` drops and re-creates the table. See [Section 12.2.9, “TRUNCATE Syntax”](#).

Memory freed by `DELETE` operations but still allocated to a specific table can also be made available for general re-use by performing a rolling restart of the cluster. See [Section 16.5.1, “Performing a Rolling Restart of the Cluster”](#).

- **Limits imposed by the cluster's configuration.** A number of hard limits exist which are configurable, but available main memory in the cluster sets limits. See the complete list of configuration parameters in [Section 16.4.4, “Configuration File”](#). Most configuration parameters can be upgraded online. These hard limits include:
 - Database memory size and index memory size (`DataMemory` and `IndexMemory`, respectively).

`DataMemory` is allocated as 32KB pages. As each `DataMemory` page is used, it is assigned to a specific table; once allocated, this memory cannot be freed except by dropping the table.

See [Section 16.4.4.5, “Defining Data Nodes”](#), for further information about `DataMemory` and `IndexMemory`.
 - The maximum number of operations that can be performed per transaction is set using the configuration parameters `MaxNoOfConcurrentOperations` and `MaxNoOfLocalOperations`.

Note

Bulk loading, `TRUNCATE TABLE`, and `ALTER TABLE` are handled as special cases by running multiple transactions, and so are not subject to this limitation.

- Different limits related to tables and indexes. For example, the maximum number of ordered indexes per table is determined by `MaxNoOfOrderedIndexes`.
- **Node and data object maximums.** The following limits apply to numbers of cluster nodes and metadata objects:
 - The maximum number of data nodes is 48.
A data node cannot have a node ID greater than 49.
 - The total maximum number of nodes in a MySQL Cluster is 63. This number includes all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers.
 - The maximum number of metadata objects in MySQL 5.1 Cluster and MySQL Cluster 5.1 Carrier Grade Edition is 20320. This limit is hard-coded.

Note

MySQL Cluster 5.1 Carrier Grade Edition users should see Section 16.13.11, “Previous MySQL Cluster Issues Resolved in MySQL 5.1”, for more information.

16.13.3. Limits Relating to Transaction Handling

A number of limitations exist in MySQL Cluster with regard to the handling of transactions. These include the following:

- **Transaction isolation level.** The `NDBCLUSTER` storage engine supports only the `READ COMMITTED` transaction isolation level. (`InnoDB`, for example, supports `READ COMMITTED`, `READ UNCOMMITTED`, `REPEATABLE READ`, and `SERIALIZABLE`.) See Section 16.8.5, “Backup Troubleshooting”, for information on how this can affect backing up and restoring Cluster databases.)

Important

If a `SELECT` from a Cluster table includes a `BLOB` or `TEXT` column, the `READ COMMITTED` transaction isolation level is converted to a read with read lock. This is done to guarantee consistency, due to the fact that parts of the values stored in columns of these types are actually read from a separate table.

- **Rollbacks.** There is no partial rollback of transactions. A duplicate key or similar error rolls back the entire transaction.
- **Transactions and memory usage.** As noted elsewhere in this chapter, MySQL Cluster does not handle large transactions well; it is better to perform a number of small transactions with a few operations each than to attempt a single large transaction containing a great many operations. Among other considerations, large transactions require very large amounts of memory. Because of this, the transactional behaviour of a number of MySQL statements is effected as described in the following list:
 - `TRUNCATE` is not transactional when used on `NDB` tables. If a `TRUNCATE` fails to empty the table, then it must be re-run until it is successful.
 - `DELETE FROM` (even with no `WHERE` clause) is transactional. For tables containing a great many rows, you may find that performance is improved by using several `DELETE FROM ... LIMIT ...` statements to “chunk” the delete operation. If your objective is to empty the table, then you may wish to use `TRUNCATE` instead.
 - **`LOAD DATA` statements.** `LOAD DATA INFILE` is not transactional when used on `NDB` tables.

Important

When executing a `LOAD DATA INFILE` statement, the `NDB` engine performs commits at irregular intervals that enable better utilization of the communication network. It is not possible to know ahead of time when such commits take place. `LOAD DATA FROM MASTER` is not supported in MySQL Cluster.

- **`ALTER TABLE` and transactions.** When copying an `NDB` table as part of an `ALTER TABLE`, the creation of the copy is non-

transactional. (In any case, this operation is rolled back when the copy is deleted.)

16.13.4. Error Handling

Starting, stopping, or restarting a node may give rise to temporary errors causing some transactions to fail. These include the following cases:

- **Temporary errors.** When first starting a node, it is possible that you may see Error 1204 `TEMPORARY FAILURE, DISTRIBUTION CHANGED` and similar temporary errors.
- **Errors due to node failure.** The stopping or failure of any data node can result in a number of different node failure errors. (However, there should be no aborted transactions when performing a planned shutdown of the cluster.)

In either of these cases, any errors that are generated must be handled within the application. This should be done by retrying the transaction.

See also [Section 16.13.2, “Limits and Differences from Standard MySQL Limits”](#).

16.13.5. Limits Associated with Database Objects

Some database objects such as tables and indexes have different limitations when using the `NDBCLUSTER` storage engine:

- **Identifiers.** Database names, table names and attribute names cannot be as long in `NDB` tables as when using other table handlers. Attribute names are truncated to 31 characters, and if not unique after truncation give rise to errors. Database names and table names can total a maximum of 122 characters. In other words, the maximum length for an `NDB` table name is 122 characters, less the number of characters in the name of the database of which that table is a part.
- **Number of tables.** The maximum number of `NDB` tables is limited to 20320.
- **Attributes per table.** The maximum number of attributes (that is, columns and indexes) per table is limited to 128.
- **Attributes per key.** The maximum number of attributes per key is 32.
- **Row size.** The maximum permitted size of any one row is 8KB. Note that each `BLOB` or `TEXT` column contributes $256 + 8 = 264$ bytes towards this total.

16.13.6. Unsupported Or Missing Features

A number of features supported by other storage engines are not supported for `NDB` tables. Trying to use any of these features in MySQL Cluster does not cause errors in or of itself; however, errors may occur in applications that expects the features to be supported or enforced:

- **Foreign key constraints.** The foreign key construct is ignored, just as it is in `MyISAM` tables.
- **OPTIMIZE operations.** `OPTIMIZE` operations are not supported.
- **LOAD TABLE ... FROM MASTER.** `LOAD TABLE ... FROM MASTER` is not supported.
- **Savepoints and rollbacks.** Savepoints and rollbacks to savepoints are ignored as in `MyISAM`.
- **Durability of commits.** There are no durable commits on disk. Commits are replicated, but there is no guarantee that logs are flushed to disk on commit.
- **Replication.** Statement-based replication is not supported. Use `--binlog-format=ROW` (or `--binlog-format=MIXED`) when setting up cluster replication. See [Section 16.10, “MySQL Cluster Replication”](#), for more information.

■ Note

See [Section 16.13.3, “Limits Relating to Transaction Handling”](#), for more information relating to limitations on transaction handling in [NDB](#).

16.13.7. Limitations Relating to Performance

The following performance issues are specific to or especially pronounced in MySQL Cluster:

- **Range scans.** There are query performance issues due to sequential access to the [NDB](#) storage engine; it is also relatively more expensive to do many range scans than it is with either [MyISAM](#) or [InnoDB](#).
- **Reliability of [Records in range](#).** The [Records in range](#) statistic is available but is not completely tested or officially supported. This may result in non-optimal query plans in some cases. If necessary, you can employ [USE INDEX](#) or [FORCE INDEX](#) to alter the execution plan. See [Section 12.2.7.2, “Index Hint Syntax”](#), for more information on how to do this.
- **Unique hash indexes.** Unique hash indexes created with [USING HASH](#) cannot be used for accessing a table if [NULL](#) is given as part of the key.

16.13.8. Issues Exclusive to MySQL Cluster

The following are limitations specific to the [NDBCLUSTER](#) storage engine:

- **Machine architecture.** All machines used in the cluster must have the same architecture. That is, all machines hosting nodes must be either big-endian or little-endian, and you cannot use a mixture of both. For example, you cannot have a management node running on a PowerPC which directs a data node that is running on an x86 machine. This restriction does not apply to machines simply running [mysql](#) or other clients that may be accessing the cluster's SQL nodes.
- **Adding and dropping of data nodes.** Online adding or dropping of data nodes is not currently possible. In such cases, the entire cluster must be restarted.
- **Binary logging.** MySQL Cluster has the following limitations or restrictions with regard to binary logging:
 - [SQL_LOG_BIN](#) has no effect on data operations; however, it is supported for schema operations.
 - MySQL Cluster cannot produce a binlog for tables having [BLOB](#) columns but no primary key.
 - Only the following schema operations are logged in a cluster binlog which is *not* on the [mysqld](#) executing the statement:
 - [CREATE TABLE](#)
 - [ALTER TABLE](#)
 - [DROP TABLE](#)
 - [CREATE DATABASE / CREATE SCHEMA](#)
 - [DROP DATABASE / DROP SCHEMA](#)
 - [CREATE TABLESPACE](#)
 - [ALTER TABLESPACE](#)
 - [DROP TABLESPACE](#)
 - [CREATE LOGFILE GROUP](#)
 - [ALTER LOGFILE GROUP](#)
 - [DROP LOGFILE GROUP](#)

See also [Section 16.13.10, “Limitations Relating to Multiple Cluster Nodes”](#).

16.13.9. Limitations Relating to Disk Data Storage

- Disk data objects are subject to the following maximums:
 - Maximum number of tablespaces: 2^{32} (4294967296)
 - Maximum number of data files per tablespace: 2^{16} (65535)
 - The theoretical maximum number of extents per tablespace data file is 2^{16} (65525); however, for practical purposes, the recommended maximum number of extents per data file is 2^8 (32768).
 - Maximum data file size: The theoretical limit is 64G; however, in MySQL 5.1, the practical upper limit is 32G. This is equivalent to 32768 extents of 1M each.

The minimum and maximum possible sizes of extents for tablespace data files are 32K and 2G, respectively. See [Section 12.1.11, “CREATE TABLESPACE Syntax”](#), for more information.
- Use of Disk Data tables is not supported when running the cluster in diskless mode. Beginning with MySQL 5.1.12, it is disallowed altogether. ([Bug#20008](#))

16.13.10. Limitations Relating to Multiple Cluster Nodes

Multiple SQL nodes. The following are issues relating to the use of multiple MySQL servers as MySQL Cluster SQL nodes, and are specific to the [NDBCLUSTER](#) storage engine:

- **ALTER TABLE operations.** [ALTER TABLE](#) is not fully locking when running multiple MySQL servers (no distributed table lock).
- **DDL operations.** DDL operations (such as [CREATE TABLE](#) or [ALTER TABLE](#)) are not safe from data node failures. If a data node fails while trying to perform one of these, the data dictionary is locked and no further DDL statements can be executed without restarting the cluster.

Multiple management nodes. When using multiple management servers:

- You must give nodes explicit IDs in connectstrings because automatic allocation of node IDs does not work across multiple management servers.
- You must take extreme care to have the same configurations for all management servers. No special checks for this are performed by the cluster.

Multiple data node processes. While it is possible to run multiple cluster processes concurrently on a single host, it is not always advisable to do so for reasons of performance and high availability, as well as other considerations. In particular, in MySQL 5.1 or MySQL Cluster 5.1 Carrier Grade Edition, we do not support for production use any MySQL Cluster deployment in which more than one [ndbd](#) process is run on a single physical machine.

Note

We may support multiple data nodes per host in a future MySQL release, following additional testing. However, in MySQL 5.1 and MySQL Cluster 5.1 Carrier Grade Edition, such configurations can be considered experimental only.

Multiple network addresses. Multiple network addresses per data node are not supported. Use of these is liable to cause problems: In the event of a data node failure, an SQL node waits for confirmation that the data node went down but never receives it because another route to that data node remains open. This can effectively make the cluster inoperable.

Note

It is possible to use multiple network hardware *interfaces* (such as Ethernet cards) for a single data node, but these must be bound to the same address. This also means that it not possible to use more than one [\[TCP\]](#) section per connection in the [config.ini](#) file. See [Section 16.4.4.7, “Cluster TCP/IP Connections”](#), for more information.

16.13.11. Previous MySQL Cluster Issues Resolved in MySQL 5.1

A number of limitations and related issues existing in earlier versions of MySQL Cluster have been resolved over the course of development of MySQL 5.1 or MySQL Cluster 5.1 Carrier Grade Edition:

- **Variable-length column support.** The **NDB Cluster** storage engine now supports variable-length column types for in-memory tables.

Previously, for example, any Cluster table having one or more **VARCHAR** fields which contained only relatively small values, much more memory and disk space were required when using the **NDBCLUSTER** storage engine than would have been the case for the same table and data using the **MyISAM** engine. In other words, in the case of a **VARCHAR** column, such a column required the same amount of storage as a **CHAR** column of the same size. In MySQL 5.1, this is no longer the case for in-memory tables, where storage requirements for variable-length column types such as **VARCHAR** and **BINARY** are comparable to those for these column types when used in **MyISAM** tables (see [Section 10.5, “Data Type Storage Requirements”](#)).

Important

For MySQL Cluster Disk Data tables, the fixed-width limitation continues to apply. See [Section 16.11, “MySQL Cluster Disk Data Tables”](#).

- **Replication with MySQL Cluster.** It is now possible to use MySQL replication with Cluster databases. For details, see [Section 16.10, “MySQL Cluster Replication”](#).
Circular Replication. Circular replication is supported for MySQL Cluster beginning with MySQL 5.1.18. See [Section 16.10.3, “Known Issues in MySQL Cluster Replication”](#).
- **auto_increment_increment and auto_increment_offset.** The **auto_increment_increment** and **auto_increment_offset** server system variables are supported for Cluster replication beginning with MySQL 5.1.20.
- **Database autodiscovery and online schema changes.** Autodiscovery of databases is now supported for multiple MySQL servers accessing the same MySQL Cluster, provided that a given **mysqld** is already running and is connected to the cluster at the time that the database is created on a different **mysqld**.

What this means is that if a **mysqld** process first connects to the cluster after a database named **db_name** has been created, you should issue a **CREATE SCHEMA db_name** statement on the “new” MySQL server when it first accesses that MySQL Cluster. Once this has been done, the “new” **mysqld** should be able to detect any tables in that database tables without errors.

This also means that online schema changes in **NDB** tables are now possible. That is, the result of operations such as **ALTER TABLE** and **CREATE INDEX** performed on one SQL node in the cluster are now visible to the cluster's other SQL nodes without any additional action being taken.

- **Backup and restore between architectures.** Beginning with MySQL 5.1.10, it is possible to perform a Cluster backup and restore between different architectures. Previously — for example — you could not back up a cluster running on a big-endian platform and then restore from that backup to a cluster running on a little-endian system. ([Bug#19255](#))
- **Character set directory.** Beginning with MySQL 5.1.10, it is possible to install MySQL with Cluster support to a non-default location and change the search path for font description files using either the **--basedir** or **--character-sets-dir** options. (Previously, **ndbd** in MySQL 5.1 searched only the default path — typically **/usr/local/mysql/share/mysql/charsets** — for character sets.)
- In MySQL 5.1, it is no longer necessary, when running multiple management servers, to restart all the cluster's data nodes to enable the management nodes to see one another.
- **Length of CREATE TABLE statements.** **CREATE TABLE** statements may be no more than 4096 characters in length. *This limitation affects MySQL 5.1.6, 5.1.7, and 5.1.8 only.* (See [Bug#17813](#))
- **IGNORE and REPLACE functionality.** In MySQL 5.1.7 and earlier, **INSERT IGNORE**, **UPDATE IGNORE**, and **REPLACE** were supported only for primary keys, but not for unique keys. It was possible to work around this issue by removing the constraint, then dropping the unique index, performing any inserts, and then adding the unique index again.

This limitation was removed for **INSERT IGNORE** and **REPLACE** in MySQL 5.1.8. (See [Bug#17431](#).)

- **AUTO_INCREMENT columns.** In MySQL 5.1.10 and earlier versions, the maximum number of tables having **AUTO_INCREMENT** columns — including those belonging to hidden primary keys — was 2048.

This limitation was lifted in MySQL 5.1.11.

MySQL Cluster 5.1 Carrier Grade Edition

The following information applies to users of MySQL Cluster 5.1 Carrier Grade Edition only. For more information about MySQL Cluster 5.1 Carrier Grade Edition, see Section 16.2, “MySQL Cluster 5.1 Carrier Grade Edition”.

Maximum number of cluster nodes. Prior to MySQL 5.1.15-ndb-6.1.1, the total maximum number of nodes in a MySQL Cluster was 63, including all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers.

Starting with MySQL 5.1.15-ndb-6.1.1, up to 255 API nodes (including MySQL servers acting as cluster SQL nodes) are supported by a single cluster. The total number of data nodes and management nodes beginning with this version is 63, of which up to 48 can be data nodes.

The limitation that a data node cannot have a node ID greater than 49 continues to apply in MySQL Cluster 5.1 Carrier Grade Edition.

The following information applies to all MySQL Cluster users.

16.14. MySQL Cluster Development Roadmap

In this section, we discuss changes in the implementation of MySQL Cluster in MySQL 5.1 and MySQL Cluster 5.1 Carrier Grade Edition as compared to MySQL 5.0.

There are a number of significant changes in the implementation of the **NDB Cluster** storage engine in MySQL 5.1 as compared to that in MySQL 5.0. For an overview of these changes, see [Section 16.14.1, “MySQL Cluster Changes in MySQL 5.1”](#)

16.14.1. MySQL Cluster Changes in MySQL 5.1

A number of new features for MySQL Cluster have been implemented in MySQL 5.1:

- **Integration of MySQL Cluster into MySQL Replication.** This makes it possible to update from any MySQL Server in the cluster and still have the MySQL Replication handled by one of the MySQL Servers in the cluster, with the state of the slave side remaining consistent with the cluster acting as the master.

See [Section 16.10, “MySQL Cluster Replication”](#).

- **Support for disk-based records.** Records on disk are now supported. Indexed columns, including the primary key hash index, must still be stored in RAM; however, all other columns can be stored on disk.

See [Section 16.11, “MySQL Cluster Disk Data Tables”](#).

- **Variable-sized records.** A column defined as **VARCHAR(255)** currently uses 260 bytes of storage independent of what is stored in any particular record. In MySQL 5.1 Cluster tables, only the portion of the column actually taken up by the record will be stored. This will make possible a reduction in space requirements for such columns by a factor of 5 in many cases.
- **User-defined partitioning.** Users can define partitions based on columns that are part of the primary key. It is possible to partition **NDB** tables based on **KEY** and **LINEAR KEY** schemes. This feature is also available for many other MySQL storage engines, which support additional partitioning types that are not available with **NDB Cluster** tables.

For additional general information about user-defined partitioning in MySQL 5.1, see [Chapter 17, Partitioning](#). Specifics of partitioning types are discussed in [Section 17.2, “Partition Types”](#).

The MySQL Server can also determine whether it is possible to “prune away” some of the partitions from the **WHERE** clause. See [Section 17.4, “Partition Pruning”](#).

- **Autodiscovery of table schema changes.** In MySQL 5.1, you no longer need to issue **FLUSH TABLES** or a “dummy” **SELECT** in order for new **NDB** tables or changes made to schemas of existing **NDB** tables on one SQL node to be visible on the cluster's other SQL nodes.

Note

When creating a new database, it is still necessary to issue a `CREATE DATABASE` or `CREATE SCHEMA` statement on each SQL node in the cluster.

See [Section 16.13.11, “Previous MySQL Cluster Issues Resolved in MySQL 5.1”](#), for more information.

16.15. MySQL Cluster Glossary

The following terms are useful to an understanding of MySQL Cluster or have specialized meanings when used in relation to it.

- **Cluster.** In its generic sense, a cluster is a set of computers functioning as a unit and working together to accomplish a single task.
NDB Cluster. This is the storage engine used in MySQL to implement data storage, retrieval, and management distributed among several computers.
MySQL Cluster. This refers to a group of computers working together using the **NDB** storage engine to support a distributed MySQL database in a *shared-nothing architecture* using *in-memory storage*.
- **Configuration files.** Text files containing directives and information regarding the cluster, its hosts, and its nodes. These are read by the cluster's management nodes when the cluster is started. See [Section 16.4.4, “Configuration File”](#), for details.
- **Backup.** A complete copy of all cluster data, transactions and logs, saved to disk or other long-term storage.
- **Restore.** Returning the cluster to a previous state, as stored in a backup.
- **Checkpoint.** Generally speaking, when data is saved to disk, it is said that a checkpoint has been reached. More specific to Cluster, it is a point in time where all committed transactions are stored on disk. With regard to the **NDB** storage engine, there are two types of checkpoints which work together to ensure that a consistent view of the cluster's data is maintained:
 - **Local Checkpoint (LCP).** This is a checkpoint that is specific to a single node; however, LCP's take place for all nodes in the cluster more or less concurrently. An LCP involves saving all of a node's data to disk, and so usually occurs every few minutes. The precise interval varies, and depends upon the amount of data stored by the node, the level of cluster activity, and other factors.
 - **Global Checkpoint (GCP).** A GCP occurs every few seconds, when transactions for all nodes are synchronized and the redo-log is flushed to disk.
- **Cluster host.** A computer making up part of a MySQL Cluster. A cluster has both a *physical* structure and a *logical* structure. Physically, the cluster consists of a number of computers, known as *cluster hosts* (or more simply as *hosts*. See also **Node** and **Node group** below.
- **Node.** This refers to a logical or functional unit of MySQL Cluster, and is sometimes also referred to as a *cluster node*. In the context of MySQL Cluster, we use the term “node” to indicate a *process* rather than a physical component of the cluster. There are three node types required to implement a working MySQL Cluster:
 - **Management nodes.** Manages the other nodes within the MySQL Cluster. It provides configuration data to the other nodes; starts and stops nodes; handles network partitioning; creates backups and restores from them, and so forth.
 - **SQL nodes.** Instances of MySQL Server which serve as front ends to data kept in the cluster's **data nodes**. Clients desiring to store, retrieve, or update data can access an SQL node just as they would any other MySQL Server, employing the usual MySQL authentication methods and APIs; the underlying distribution of data between node groups is transparent to users and applications. SQL nodes access the cluster's databases as a whole without regard to the data's distribution across different data nodes or cluster hosts.
 - **Data nodes.** These nodes store the actual data. Table data fragments are stored in a set of node groups; each node group stores a different subset of the table data. Each of the nodes making up a node group stores a replica of the fragment for which that node group is responsible. Currently, a single cluster can support up to 48 data nodes total.

It is possible for more than one node to co-exist on a single machine. (In fact, it is even possible to set up a complete cluster on one machine, although one would almost certainly *not* want to do this in a production environment.) It may be helpful to remember that, when working with MySQL Cluster, the term *host* refers to a physical component of the cluster whereas a *node* is a logical or func-

tional component (that is, a process).

Note Regarding Terms. In volder versions of the MySQL Cluster documentation, data nodes were sometimes referred to as “database nodes”. The term “storage nodes” has also been used. In addition, SQL nodes were sometimes known as “client nodes”. This older terminology has been deprecated to minimize confusion, and for this reason should be avoided. They are also often referred to as “API nodes” — an SQL node is actually an API node that provides an SQL interface to the cluster.

- **Node group.** A set of data nodes. All data nodes in a node group contain the same data (fragments), and all nodes in a single group should reside on different hosts. It is possible to control which nodes belong to which node groups.

For more information, see [Section 16.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”](#).

- **Node failure.** MySQL Cluster is not solely dependent upon the functioning of any single node making up the cluster; the cluster can continue to run if one or more nodes fail. The precise number of node failures that a given cluster can tolerate depends upon the number of nodes and the cluster's configuration.
- **Node restart.** The process of restarting a failed cluster node.
- **Initial node restart.** The process of starting a cluster node with its filesystem removed. This is sometimes used in the course of software upgrades and in other special circumstances.
- **System crash (or system failure).** This can occur when so many cluster nodes have failed that the cluster's state can no longer be guaranteed.
- **System restart.** The process of restarting the cluster and reinitializing its state from disk logs and checkpoints. This is required after either a planned or an unplanned shutdown of the cluster.
- **Fragment.** A portion of a database table; in the [NDB](#) storage engine, a table is broken up into and stored as a number of fragments. A fragment is sometimes also called a “partition”; however, “fragment” is the preferred term. Tables are fragmented in MySQL Cluster in order to facilitate load balancing between machines and nodes.
- **Replica.** Under the [NDB](#) storage engine, each table fragment has number of replicas stored on other data nodes in order to provide redundancy. Currently, there may be up four replicas per fragment.
- **Transporter.** A protocol providing data transfer between nodes. MySQL Cluster currently supports four different types of transporter connections:
 - **TCP/IP.** This is, of course, the familiar network protocol that underlies HTTP, FTP (and so on) on the Internet. TCP/IP can be used for both local and remote connections.
 - **SCI.** Scalable Coherent Interface is a high-speed protocol used in building multiprocessor systems and parallel-processing applications. Use of SCI with MySQL Cluster requires specialized hardware, as discussed in [Section 16.12.1, “Configuring MySQL Cluster to use SCI Sockets”](#). For a basic introduction to SCI, see [this essay at dolphinics.com](#).
 - **SHM.** Unix-style shared memory segments. Where supported, SHM is used automatically to connect nodes running on the same host. The [Unix man page for shmop\(2\)](#) is a good place to begin obtaining additional information about this topic.

Note

The cluster transporter is internal to the cluster. Applications using MySQL Cluster communicate with SQL nodes just as they do with any other version of MySQL Server (via TCP/IP, or through the use of Unix socket files or Windows named pipes). Queries can be sent and results retrieved using the standard MySQL client APIs.

- **NDB.** This stands for Network Database, and refers to the storage engine used to enable MySQL Cluster. The [NDB](#) storage engine supports all the usual MySQL data types and SQL statements, and is ACID-compliant. This engine also provides full support for transactions (commits and rollbacks).
- **Shared-nothing architecture.** The ideal architecture for a MySQL Cluster. In a true shared-nothing setup, each node runs on a separate host. The advantage such an arrangement is that there no single host or node can act as single point of failure or as a performance bottle neck for the system as a whole.
- **In-memory storage.** All data stored in each data node is kept in memory on the node's host computer. For each data node in the cluster, you must have available an amount of RAM equal to the size of the database times the number of replicas, divided by the number of data nodes. Thus, if the database takes up 1GB of memory, and you want to set up the cluster with four replicas and eight data nodes, a minimum of 500MB memory will be required per node. Note that this is in addition to any requirements for the operating system and any other applications that might be running on the host.

In MySQL 5.1, it is also possible to create *Disk Data* tables where non-indexed columns are stored on disk, thus reducing the memory footprint required by the cluster. Note that indexes and indexed column data are still stored in RAM. See [Section 16.11, “MySQL Cluster Disk Data Tables”](#).

- **Table.** As is usual in the context of a relational database, the term “table” denotes a set of identically structured records. In MySQL Cluster, a database table is stored in a data node as a set of fragments, each of which is replicated on additional data nodes. The set of data nodes replicating the same fragment or set of fragments is referred to as a *node group*.
- **Cluster programs.** These are command-line programs used in running, configuring, and administering MySQL Cluster. They include both server daemons:

- `ndbd`:

The data node daemon (runs a data node process)

- `ndb_mgmd`:

The management server daemon (runs a management server process)

and client programs:

- `ndb_mgm`:

The management client (provides an interface for executing management commands)

- `ndb_waiter`:

Used to verify status of all nodes in a cluster

- `ndb_restore`:

Restores cluster data from backup

For more about these programs and their uses, see [Section 16.6, “Process Management in MySQL Cluster”](#).

- **Event log.** MySQL Cluster logs events by category (startup, shutdown, errors, checkpoints, and so on), priority, and severity. A complete listing of all reportable events may be found in [Section 16.7.3, “Event Reports Generated in MySQL Cluster”](#). Event logs are of two types:
 - **Cluster log.** Keeps a record of all desired reportable events for the cluster as a whole.
 - **Node log.** A separate log which is also kept for each individual node.

Under normal circumstances, it is necessary and sufficient to keep and examine only the cluster log. The node logs need be consulted only for application development and debugging purposes.

Chapter 17. Partitioning

This chapter discusses *user-defined partitioning*, as implemented in MySQL 5.1.

An introduction to partitioning and partitioning concepts may be found in [Section 17.1, “Overview of Partitioning in MySQL”](#).

MySQL supports several types of partitioning, which are discussed in [Section 17.2, “Partition Types”](#), as well as subpartitioning, which is described in [Section 17.2.5, “Subpartitioning”](#).

Methods of adding, removing, and altering partitions in existing partitioned tables are covered in [Section 17.3, “Partition Management”](#).

Table maintenance commands for use with partitioned tables are discussed in [Section 17.3.3, “Maintenance of Partitions”](#).

Important

Partitioned tables created with MySQL versions prior to 5.1.6 cannot be read by a 5.1.6 or later MySQL Server. In addition, the `INFORMATION_SCHEMA.TABLES` table cannot be used if such tables are present on a 5.1.6 server. Beginning with MySQL 5.1.7, a suitable warning message is generated instead, to alert the user that incompatible partitioned tables have been found by the server.

If you are using partitioned tables which were created in MySQL 5.1.5 or earlier, be sure to see [Section C.1.24, “Changes in release 5.1.6 \(01 February 2006\)”](#) for more information and suggested workarounds *before* upgrading to MySQL 5.1.6 or later.

The partitioning implementation in MySQL 5.1 is still undergoing development. For known issues with MySQL partitioning, see [Section 17.5, “Restrictions and Limitations on Partitioning”](#), where we have noted these.

You may also find the following resources to be useful when working with partitioned tables.

Additional Resources. Other sources of information about user-defined partitioning in MySQL include the following:

- [MySQL Partitioning Forum](#)

This is the official discussion forum for those interested in or experimenting with MySQL Partitioning technology. It features announcements and updates from MySQL developers and others. It is monitored by members of the Partitioning Development and Documentation Teams.

- [Mikael Ronström's Blog](#)

MySQL Partitioning Architect and Lead Developer Mikael Ronström frequently posts articles here concerning his work with MySQL Partitioning and MySQL Cluster.

- [PlanetMySQL](#)

A MySQL news site featuring MySQL-related blogs, which should be of interest to anyone using my MySQL. We encourage you to check here for links to blogs kept by those working with MySQL Partitioning, or to have your own blog added to those covered.

MySQL 5.1 binaries are now available from <http://dev.mysql.com/downloads/mysql/5.1.html>. However, for the latest partitioning bug-fixes and feature additions, you can obtain the source from our BitKeeper repository. To enable partitioning, you need to compile the server using the `--with-partition` option. For more information about building MySQL, see [Section 2.9, “MySQL Installation Using a Source Distribution”](#). If you have problems compiling a partitioning-enabled MySQL 5.1 build, check the [MySQL Partitioning Forum](#) and ask for assistance there if you don't find a solution to your problem already posted.

17.1. Overview of Partitioning in MySQL

This section provides a conceptual overview of partitioning in MySQL 5.1.

For information on partitioning restrictions and feature limitations, see [Section 17.5, “Restrictions and Limitations on Partitioning”](#).

The SQL standard does not provide much in the way of guidance regarding the physical aspects of data storage. The SQL language itself is intended to work independently of any data structures or media underlying the schemas, tables, rows, or columns with which it works. Nonetheless, most advanced database management systems have evolved some means of determining the physical location to be

used for storing specific pieces of data in terms of the filesystem, hardware or even both. In MySQL, the **InnoDB** storage engine has long supported the notion of a tablespace, and the MySQL Server, even prior to the introduction of partitioning, could be configured to employ different physical directories for storing different databases (see [Section 6.6.1, “Using Symbolic Links”](#), for an explanation of how this is done).

Partitioning takes this notion a step further, by allowing you to distribute portions of individual tables across a filesystem according to rules which you can set largely as needed. In effect, different portions of a table are stored as separate tables in different locations. The user-selected rule by which the division of data is accomplished is known as a *partitioning function*, which in MySQL can be the modulus, simple matching against a set of ranges or value lists, an internal hashing function, or a linear hashing function. The function is selected according to the partitioning type specified by the user, and takes as its parameter the value of a user-supplied expression. This expression can be either an integer column value, or a function acting on one or more column values and returning an integer. The value of this expression is passed to the partitioning function, which returns an integer value representing the number of the partition in which that particular record should be stored. This function must be non-constant and non-random. It may not contain any queries, but may use an SQL expression that is valid in MySQL, as long as that expression returns either **NULL** or an integer *interval* such that

```
-MAXVALUE < interval < MAXVALUE
```

(**MAXVALUE** is used to represent the greatest possible positive integer.) There are some additional restrictions on partitioning functions; see [Section 17.5, “Restrictions and Limitations on Partitioning”](#), for more information about these.

Examples of partitioning functions can be found in the discussions of partitioning types later in this chapter (see [Section 17.2, “Partition Types”](#)), as well as in the partitioning syntax descriptions given in [Section 12.1.10, “CREATE TABLE Syntax”](#).

This is known as *horizontal partitioning* — that is, different rows of a table may be assigned to different physical partitions. MySQL 5.1 does not support *vertical partitioning*, in which different columns of a table are assigned to different physical partitions. There are not at this time any plans to introduce vertical partitioning into MySQL 5.1.

Partitioning support is included in the **-max** releases of MySQL 5.1 (that is, 5.1 **-max** binaries are built using **--with-partition**). If the MySQL binary is built with partitioning support, nothing further needs to be done in order to enable it (for example, no special entries are required in your **my.cnf** file). You can determine whether your MySQL server supports partitioning by means of a **SHOW VARIABLES** command such as this one:

```
mysql> SHOW VARIABLES LIKE '%partition%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| have_partitioning | YES   |
+-----+-----+
1 row in set (0.00 sec)
```

If you do not see the **have_partitioning** variable with the value **YES** listed as shown above in the output of an appropriate **SHOW VARIABLES**, then your version of MySQL does not support partitioning.

Prior to MySQL 5.1.6, this variable was named **have_partition_engine**. ([Bug#16718](#))

For creating partitioned tables, you can use most storage engines that are supported by your MySQL server; the MySQL partitioning engine runs in a separate layer and can interact with any of these. In MySQL 5.1, all partitions of the same partitioned table must use the same storage engine; for example, you cannot use **MyISAM** for one partition and **InnoDB** for another. However, there is nothing preventing you from using different storage engines for different partitioned tables on the same MySQL server or even in the same database.

Note

MySQL partitioning cannot be used with the **MERGE** or **CSV** storage engines. Beginning with MySQL 5.1.15, **FEDERATED** tables also cannot be partitioned ([Bug#22451](#)). Prior to MySQL 5.1.6, it was also not feasible to create a partitioned table using the **BLACKHOLE** storage engine ([Bug#14524](#)). Partitioning by **KEY** is supported for use with the **NDB-Cluster** storage engine, but other types of user-defined partitioning are not supported for Cluster tables in MySQL 5.1.

To employ a particular storage engine for a partitioned table, it is necessary only to use the **[STORAGE] ENGINE** option just as you would for a non-partitioned table. However, you should keep in mind that **[STORAGE] ENGINE** (and other table options) need to be listed *before* any partitioning options are used in a **CREATE TABLE** statement. This example shows how to create a table that is partitioned by hash into 6 partitions and which uses the **InnoDB** storage engine:

```
CREATE TABLE ti (id INT, amount DECIMAL(7,2), tr_date DATE)
ENGINE=INNODB
PARTITION BY HASH( MONTH(tr_date) )
PARTITIONS 6;
```

(Note that each **PARTITION** clause can include a **[STORAGE] ENGINE** option, but in MySQL 5.1 this has no effect.)

Important

Partitioning applies to all data and indexes of a table; you cannot partition only the data and not the indexes, or *vice versa*, nor can you partition only a portion of the table.

Data and indexes for each partition can be assigned to a specific directory using the **DATA DIRECTORY** and **INDEX DIRECTORY** options for the **PARTITION** clause of the **CREATE TABLE** statement used to create the partitioned table.

Note

Prior to MySQL 5.1.18, these options were permitted even when the **NO_DIR_IN_CREATE** server SQL mode was in effect. ([Bug#24633](#))

Important

On Windows, you must use the **/** character and not the **** character when specifying paths for **DATA DIRECTORY** and **INDEX DIRECTORY**, as shown in this example:

```
CREATE TABLE sales1 (
  id INT(11) NOT NULL AUTO_INCREMENT PRIMARY KEY,
  sales_date DATE NOT NULL DEFAULT '0000-00-00'
) ENGINE=InnoDB DEFAULT CHARSET=latin1
PARTITION BY RANGE(id)
(
  PARTITION p0 VALUES LESS THAN (5000)
    DATA DIRECTORY='d:/s1/data/'
    INDEX DIRECTORY = 'd:/s1/idx/',

  PARTITION p1 VALUES LESS THAN (10000)
    DATA DIRECTORY='e:/s1/data/'
    INDEX DIRECTORY = 'e:/s1/idx/',

  PARTITION p1 VALUES LESS THAN MAXVALUE
    DATA DIRECTORY='f:/s1/data/'
    INDEX DIRECTORY = 'f:/s1/idx/'
);
```

In addition, **MAX_ROWS** and **MIN_ROWS** can be used to determine the maximum and minimum numbers of rows, respectively, that can be stored in each partition. See [Section 17.3, “Partition Management”](#), for more information on these options.

Some of the advantages of partitioning include:

- Being able to store more data in one table than can be held on a single disk or filesystem partition.
- Data that loses its usefulness can often be easily removed from the table by dropping the partition containing only that data. Conversely, the process of adding new data can in some cases be greatly facilitated by adding a new partition specifically for that data.
- Some queries can be greatly optimized in virtue of the fact that data satisfying a given **WHERE** clause can be stored only on one or more partitions, thereby excluding any remaining partitions from the search. Because partitions can be altered after a partitioned table has been created, you can reorganize your data to enhance frequent queries that may not have been so when the partitioning scheme was first set up. This capability, sometimes referred to as *partition pruning*, was implemented in MySQL 5.1.6. For additional information, see [Section 17.4, “Partition Pruning”](#).

Other benefits usually associated with partitioning include those in the following list. These features are not currently implemented in MySQL Partitioning, but are high on our list of priorities.

- Queries involving aggregate functions such as **SUM()** and **COUNT()** can easily be parallelized. A simple example of such a query might be **SELECT salesperson_id, COUNT(orders) as order_total FROM sales GROUP BY salesperson_id;**. By “parallelized,” we mean that the query can be run simultaneously on each partition, and the final result obtained merely by summing the results obtained for all partitions.
- Achieving greater query throughput in virtue of spreading data seeks over multiple disks.

Be sure to check this section and chapter frequently for updates as Partitioning development continues.

17.2. Partition Types

This section discusses the types of partitioning which are available in MySQL 5.1. These include:

- **RANGE partitioning:** Assigns rows to partitions based on column values falling within a given range. See [Section 17.2.1, “RANGE Partitioning”](#).
- **LIST partitioning:** Similar to partitioning by range, except that the partition is selected based on columns matching one of a set of discrete values. See [Section 17.2.2, “LIST Partitioning”](#).
- **HASH partitioning:** A partition is selected based on the value returned by a user-defined expression that operates on column values in rows to be inserted into the table. The function may consist of any expression valid in MySQL that yields a non-negative integer value. See [Section 17.2.3, “HASH Partitioning”](#).
- **KEY partitioning:** Similar to partitioning by hash, except that only one or more columns to be evaluated are supplied, and the MySQL server provides its own hashing function. These columns can contain other than integer values, since the hashing function supplied by MySQL guarantees an integer result regardless of the column data type. See [Section 17.2.4, “KEY Partitioning”](#).

A very common use of database partitioning is to segregate data by date. Some database systems support explicit date partitioning, which MySQL does not implement in 5.1. However, it is not difficult in MySQL to create partitioning schemes based on [DATE](#), [TIME](#), or [DATETIME](#) columns, or based on expressions making use of such columns.

When partitioning by [KEY](#) or [LINEAR KEY](#), you can use a [DATE](#), [TIME](#), or [DATETIME](#) column as the partitioning column without performing any modification of the column value. For example, this table creation statement is perfectly valid in MySQL:

```
CREATE TABLE members (
  firstname VARCHAR(25) NOT NULL,
  lastname VARCHAR(25) NOT NULL,
  username VARCHAR(16) NOT NULL,
  email VARCHAR(35),
  joined DATE NOT NULL
)
PARTITION BY KEY(joined)
PARTITIONS 6;
```

MySQL's other partitioning types, however, require a partitioning expression that yields an integer value or [NULL](#). If you wish to use date-based partitioning by [RANGE](#), [LIST](#), [HASH](#), or [LINEAR HASH](#), you can simply employ a function that operates on a [DATE](#), [TIME](#), or [DATETIME](#) column and returns such a value, as shown here:

```
CREATE TABLE members (
  firstname VARCHAR(25) NOT NULL,
  lastname VARCHAR(25) NOT NULL,
  username VARCHAR(16) NOT NULL,
  email VARCHAR(35),
  joined DATE NOT NULL
)
PARTITION BY RANGE( YEAR(joined) ) (
  PARTITION p0 VALUES LESS THAN (1960),
  PARTITION p1 VALUES LESS THAN (1970),
  PARTITION p2 VALUES LESS THAN (1980),
  PARTITION p3 VALUES LESS THAN (1990),
  PARTITION p4 VALUES LESS THAN MAXVALUE
);
```

Additional examples of partitioning using dates may be found here:

- [Section 17.2.1, “RANGE Partitioning”](#)
- [Section 17.2.3, “HASH Partitioning”](#)
- [Section 17.2.3.1, “LINEAR HASH Partitioning”](#)

For more complex examples of date-based partitioning, see:

- [Section 17.4, “Partition Pruning”](#)

- [Section 17.2.5, “Subpartitioning”](#)

MySQL partitioning is optimized for use with the `TO_DAYS()` and `YEAR()` functions. However, you can use other date and time functions that return an integer or `NULL`, such as `WEEKDAY()`, `DAYOFYEAR()`, or `MONTH()`. See [Section 11.6, “Date and Time Functions”](#), for more information about such functions.

It is important to remember — regardless of the type of partitioning that you use — that partitions are always numbered automatically and in sequence when created, starting with `0`. When a new row is inserted into a partitioned table, it is these partition numbers that are used in identifying the correct partition. For example, if your table uses 4 partitions, these partitions are numbered `0`, `1`, `2`, and `3`. For the `RANGE` and `LIST` partitioning types, it is necessary to ensure that there is a partition defined for each partition number. For `HASH` partitioning, the user function employed must return an integer value greater than `0`. For `KEY` partitioning, this issue is taken care of automatically by the hashing function which the MySQL server employs internally.

Names of partitions generally follow the rules governing other MySQL identifiers, such as those for tables and databases. However, you should note that partition names are not case-sensitive. For example, the following `CREATE TABLE` statement fails as shown:

```
mysql> CREATE TABLE t2 (val INT)
-> PARTITION BY LIST(val)(
->     PARTITION mypart VALUES IN (1,3,5),
->     PARTITION MyPart VALUES IN (2,4,6)
-> );
ERROR 1488 (HY000): Duplicate partition name mypart
```

Failure occurs because MySQL sees no difference between the partition names `mypart` and `MyPart`.

When you specify the number of partitions for the table, this must be expressed as a positive, non-zero integer literal with no leading zeroes, and may not be an expression such as `0.8E+01` or `6-2`, even if it evaluates as an integer. (Beginning with MySQL 5.1.12, decimal fractions are no longer truncated, but instead are disallowed entirely.)

In the sections that follow, we do not necessarily provide all possible forms for the syntax that can be used for creating each partition type; this information may be found in [Section 12.1.10, “CREATE TABLE Syntax”](#).

17.2.1. RANGE Partitioning

A table that is partitioned by range is partitioned in such a way that each partition contains rows for which the partitioning expression value lies within a given range. Ranges should be contiguous but not overlapping, and are defined using the `VALUES LESS THAN` operator. For the next few examples, suppose that you are creating a table such as the following to hold personnel records for a chain of 20 video stores, numbered 1 through 20:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
);
```

This table can be partitioned by range in a number of ways, depending on your needs. One way would be to use the `store_id` column. For instance, you might decide to partition the table 4 ways by adding a `PARTITION BY RANGE` clause as shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
  PARTITION p0 VALUES LESS THAN (6),
  PARTITION p1 VALUES LESS THAN (11),
  PARTITION p2 VALUES LESS THAN (16),
  PARTITION p3 VALUES LESS THAN (21)
);
```

In this partitioning scheme, all rows corresponding to employees working at stores 1 through 5 are stored in partition `p0`, to those employed at stores 6 through 10 are stored in partition `p1`, and so on. Note that each partition is defined in order, from lowest to highest.

This is a requirement of the **PARTITION BY RANGE** syntax; you can think of it as being analogous to a **switch ... case** in C or Java in this regard.

It is easy to determine that a new row containing the data (72, 'Michael', 'Widenius', '1998-06-25', NULL, 13) is inserted into partition **p2**, but what happens when your chain adds a 21st store? Under this scheme, there is no rule that covers a row whose **store_id** is greater than 20, so an error results because the server does not know where to place it. You can keep this from occurring by using a “catchall” **VALUES LESS THAN** clause in the **CREATE TABLE** statement that provides for all values greater than highest value explicitly named:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
  PARTITION p0 VALUES LESS THAN (6),
  PARTITION p1 VALUES LESS THAN (11),
  PARTITION p2 VALUES LESS THAN (16),
  PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

MAXVALUE represents the greatest possible integer value. Now, any rows whose **store_id** column value is greater than or equal to 16 (the highest value defined) are stored in partition **p3**. At some point in the future — when the number of stores has increased to 25, 30, or more — you can use an **ALTER TABLE** statement to add new partitions for stores 21-25, 26-30, and so on (see [Section 17.3, “Partition Management”](#), for details of how to do this).

In much the same fashion, you could partition the table based on employee job codes — that is, based on ranges of **job_code** column values. For example — assuming that two-digit job codes are used for regular (in-store) workers, three-digit codes are used for office and support personnel, and four-digit codes are used for management positions — you could create the partitioned table using the following:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
)
PARTITION BY RANGE (job_code) (
  PARTITION p0 VALUES LESS THAN (100),
  PARTITION p1 VALUES LESS THAN (1000),
  PARTITION p2 VALUES LESS THAN (10000)
);
```

In this instance, all rows relating to in-store workers would be stored in partition **p0**, those relating to office and support staff in **p1**, and those relating to managers in partition **p2**.

It is also possible to use an expression in **VALUES LESS THAN** clauses. However, MySQL must be able to evaluate the expression's return value as part of a **LESS THAN (<)** comparison.

Rather than splitting up the table data according to store number, you can use an expression based on one of the two **DATE** columns instead. For example, let us suppose that you wish to partition based on the year that each employee left the company; that is, the value of **YEAR(separated)**. An example of a **CREATE TABLE** statement that implements such a partitioning scheme is shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY RANGE ( YEAR(separated) ) (
  PARTITION p0 VALUES LESS THAN (1991),
  PARTITION p1 VALUES LESS THAN (1996),
  PARTITION p2 VALUES LESS THAN (2001),
  PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

In this scheme, for all employees who left before 1991, the rows are stored in partition `p0`; for those who left in the years 1991 through 1995, in `p1`; for those who left in the years 1996 through 2000, in `p2`; and for any workers who left after the year 2000, in `p3`.

Range partitioning is particularly useful when:

- You want or need to delete “old” data. If you are using the partitioning scheme shown immediately above, you can simply use `ALTER TABLE employees DROP PARTITION p0`; to delete all rows relating to employees who stopped working for the firm prior to 1991. (See [Section 12.1.4, “ALTER TABLE Syntax”](#), and [Section 17.3, “Partition Management”](#), for more information.) For a table with a great many rows, this can be much more efficient than running a `DELETE` query such as `DELETE FROM employees WHERE YEAR(separated) <= 1990`;
- You want to use a column containing date or time values, or containing values arising from some other series.
- You frequently run queries that depend directly on the column used for partitioning the table. For example, when executing a query such as `SELECT COUNT(*) FROM employees WHERE YEAR(separated) = 2000 GROUP BY store_id`;, MySQL can quickly determine that only partition `p2` needs to be scanned because the remaining partitions cannot contain any records satisfying the `WHERE` clause. See [Section 17.4, “Partition Pruning”](#), for more information about how this is accomplished.

17.2.2. LIST Partitioning

List partitioning in MySQL is similar to range partitioning in many ways. As in partitioning by `RANGE`, each partition must be explicitly defined. The chief difference is that, in list partitioning, each partition is defined and selected based on the membership of a column value in one of a set of value lists, rather than in one of a set of contiguous ranges of values. This is done by using `PARTITION BY LIST(expr)` where `expr` is a column value or an expression based on a column value and returning an integer value, and then defining each partition by means of a `VALUES IN (value_list)`, where `value_list` is a comma-separated list of integers.

Note

In MySQL 5.1, it is possible to match against only a list of integers (and possibly `NULL` — see [Section 17.2.6, “How MySQL Partitioning Handles NULL Values”](#)) when partitioning by `LIST`.

Unlike the case with partitions defined by range, list partitions do not need to be declared in any particular order. For more detailed syntactical information, see [Section 12.1.10, “CREATE TABLE Syntax”](#).

For the examples that follow, we assume that the basic definition of the table to be partitioned is provided by the `CREATE TABLE` statement shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
);
```

(This is the same table used as a basis for the examples in [Section 17.2.1, “RANGE Partitioning”](#).)

Suppose that there are 20 video stores distributed among 4 franchises as shown in the following table:

Region	Store ID Numbers
North	3, 5, 6, 9, 17
East	1, 2, 10, 11, 19, 20
West	4, 12, 13, 14, 18
Central	7, 8, 15, 16

To partition this table in such a way that rows for stores belonging to the same region are stored in the same partition, you could use the `CREATE TABLE` statement shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
```

```

    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)
PARTITION BY LIST(store_id) (
    PARTITION pNorth VALUES IN (3,5,6,9,17),
    PARTITION pEast VALUES IN (1,2,10,11,19,20),
    PARTITION pWest VALUES IN (4,12,13,14,18),
    PARTITION pCentral VALUES IN (7,8,15,16)
);

```

This makes it easy to add or drop employee records relating to specific regions to or from the table. For instance, suppose that all stores in the West region are sold to another company. All rows relating to employees working at stores in that region can be deleted with the query `ALTER TABLE employees DROP PARTITION pWest;`, which can be executed much more efficiently than the equivalent `DELETE` statement `DELETE FROM employees WHERE store_id IN (4,12,13,14,18);`.

As with [RANGE](#) partitioning, it is possible to combine [LIST](#) partitioning with partitioning by hash or key to produce a composite partitioning (subpartitioning). See [Section 17.2.5, “Subpartitioning”](#).

17.2.3. HASH Partitioning

Partitioning by [HASH](#) is used primarily to ensure an even distribution of data among a predetermined number of partitions. With range or list partitioning, you must specify explicitly into which partition a given column value or set of column values is to be stored; with hash partitioning, MySQL takes care of this for you, and you need only specify a column value or expression based on a column value to be hashed and the number of partitions into which the partitioned table is to be divided.

To partition a table using [HASH](#) partitioning, it is necessary to append to the `CREATE TABLE` statement a `PARTITION BY HASH (expr)` clause, where *expr* is an expression that returns an integer. This can simply be the name of a column whose type is one of MySQL's integer types. In addition, you will most likely want to follow this with a `PARTITIONS num` clause, where *num* is a non-negative integer representing the number of partitions into which the table is to be divided.

For example, the following statement creates a table that uses hashing on the `store_id` column and is divided into 4 partitions:

```

CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)
PARTITION BY HASH(store_id)
PARTITIONS 4;

```

If you do not include a `PARTITIONS` clause, the number of partitions defaults to `1`.

Using the `PARTITIONS` keyword without a number following it results in a syntax error.

You can also use an SQL expression that returns an integer for *expr*. For instance, you might want to partition based on the year in which an employee was hired. This can be done as shown here:

```

CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)
PARTITION BY HASH( YEAR(hired) )
PARTITIONS 4;

```

You may use any function or other expression for *expr* that is valid in MySQL, so long as it returns a non-constant, non-random integer value. (In other words, it should be varying but deterministic.) However, you should keep in mind that this expression is evaluated each time a row is inserted or updated (or possibly deleted); this means that very complex expressions may give rise to performance issues, particularly when performing operations (such as batch inserts) that affect a great many rows at one time.

The most efficient hashing function is one which operates upon a single table column and whose value increases or decreases consistently with the column value, as this allows for “pruning” on ranges of partitions. That is, the more closely that the expression varies with the value of the column on which it is based, the more efficiently MySQL can use the expression for hash partitioning.

For example, where `date_col` is a column of type `DATE`, then the expression `TO_DAYS(date_col)` is said to vary directly with the value of `date_col`, because for every change in the value of `date_col`, the value of the expression changes in a consistent manner. The variance of the expression `YEAR(date_col)` with respect to `date_col` is not quite as direct as that of `TO_DAYS(date_col)`, because not every possible change in `date_col` produces an equivalent change in `YEAR(date_col)`. Even so, `YEAR(date_col)` is a good candidate for a hashing function, because it varies directly with a portion of `date_col` and there is no possible change in `date_col` that produces a disproportionate change in `YEAR(date_col)`.

By way of contrast, suppose that you have a column named `int_col` whose type is `INT`. Now consider the expression `POW(5-int_col,3) + 6`. This would be a poor choice for a hashing function because a change in the value of `int_col` is not guaranteed to produce a proportional change in the value of the expression. Changing the value of `int_col` by a given amount can produce widely different changes in the value of the expression. For example, changing `int_col` from 5 to 6 produces a change of -1 in the value of the expression, but changing the value of `int_col` from 6 to 7 produces a change of -7 in the expression value.

In other words, the more closely the graph of the column value *versus* the value of the expression follows a straight line as traced by the equation $y=nx$ where n is some nonzero constant, the better the expression is suited to hashing. This has to do with the fact that the more nonlinear an expression is, the more uneven the distribution of data among the partitions it tends to produce.

In theory, pruning is also possible for expressions involving more than one column value, but determining which of such expressions are suitable can be quite difficult and time-consuming. For this reason, the use of hashing expressions involving multiple columns is not particularly recommended.

When `PARTITION BY HASH` is used, MySQL determines which partition of `num` partitions to use based on the modulus of the result of the user function. In other words, for an expression `expr`, the partition in which the record is stored is partition number N , where $N = \text{MOD}(\text{expr}, \text{num})$. For example, suppose table `t1` is defined as follows, so that it has 4 partitions:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY HASH( YEAR(col3) )
PARTITIONS 4;
```

If you insert a record into `t1` whose `col3` value is `'2005-09-15'`, then the partition in which it is stored is determined as follows:

```
MOD(YEAR('2005-09-01'),4)
= MOD(2005,4)
= 1
```

MySQL 5.1 also supports a variant of `HASH` partitioning known as *linear hashing* which employs a more complex algorithm for determining the placement of new rows inserted into the partitioned table. See [Section 17.2.3.1, “LINEAR HASH Partitioning”](#), for a description of this algorithm.

The user function is evaluated each time a record is inserted or updated. It may also — depending on the circumstances — be evaluated when records are deleted.

Note

If a table to be partitioned has a `UNIQUE` key, then any columns supplied as arguments to the `HASH` user function or to the `KEY's column_list` must be part of that key.

17.2.3.1. LINEAR HASH Partitioning

MySQL also supports linear hashing, which differs from regular hashing in that linear hashing utilizes a linear powers-of-two algorithm whereas regular hashing employs the modulus of the hashing function's value.

Syntactically, the only difference between linear-hash partitioning and regular hashing is the addition of the `LINEAR` keyword in the `PARTITION BY` clause, as shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
```

```
PARTITION BY LINEAR HASH( YEAR(hired) )
PARTITIONS 4;
```

Given an expression *expr*, the partition in which the record is stored when linear hashing is used is partition number *N* from among *num* partitions, where *N* is derived according to the following algorithm:

1. Find the next power of 2 greater than *num*. We call this value *V*; it can be calculated as:

```
V = POWER(2, CEILING(LOG(2, num)))
```

(For example, suppose that *num* is 13. Then $\text{LOG}(2, 13)$ is 3.7004397181411. $\text{CEILING}(3.7004397181411)$ is 4, and $V = \text{POWER}(2, 4)$, which is 16.)

2. Set $N = F(\text{column\_list}) \& (V - 1)$.
3. While $N \geq \text{num}$:
 - Set $V = \text{CEIL}(V / 2)$
 - Set $N = N \& (V - 1)$

For example, suppose that the table *t1*, using linear hash partitioning and having 6 partitions, is created using this statement:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY LINEAR HASH( YEAR(col3) )
PARTITIONS 6;
```

Now assume that you want to insert two records into *t1* having the *col3* column values '2003-04-14' and '1998-10-19'. The partition number for the first of these is determined as follows:

```
V = POWER(2, CEILING( LOG(2, 7) )) = 8
N = YEAR('2003-04-14') & (8 - 1)
  = 2003 & 7
  = 3
(3 >= 6 is FALSE: record stored in partition #3)
```

The number of the partition where the second record is stored is calculated as shown here:

```
V = 8
N = YEAR('1998-10-19') & (8-1)
  = 1998 & 7
  = 6
(6 >= 6 is TRUE: additional step required)
N = 6 & CEILING(5 / 2)
  = 6 & 3
  = 2
(2 >= 6 is FALSE: record stored in partition #2)
```

The advantage in partitioning by linear hash is that the adding, dropping, merging, and splitting of partitions is made much faster, which can be beneficial when dealing with tables containing extremely large amounts (terabytes) of data. The disadvantage is that data is less likely to be evenly distributed between partitions as compared with the distribution obtained using regular hash partitioning.

17.2.4. KEY Partitioning

Partitioning by key is similar to partitioning by hash, except that where hash partitioning employs a user-defined expression, the hashing function for key partitioning is supplied by the MySQL server. MySQL Cluster uses `MD5()` for this purpose; for tables using other storage engines, the server employs its own internal hashing function which is based on the same algorithm as `PASSWORD()`.

The syntax rules for `CREATE TABLE ... PARTITION BY KEY` are similar to those for creating a table that is partitioned by hash. The major differences are that:

- **KEY** is used rather than **HASH**.
- **KEY** takes only a list of one or more column names. Beginning with MySQL 5.1.5, the column or columns used as the partitioning key must comprise part or all of the table's primary key, if the table has one.

Beginning with MySQL 5.1.6, **KEY** takes a list of zero or more column names. Where no column name is specified as the partitioning key, the table's primary key is used, if there is one. For example, the following **CREATE TABLE** statement is valid in MySQL 5.1.6 or later:

```
CREATE TABLE k1 (
  id INT NOT NULL PRIMARY KEY,
  name VARCHAR(20)
)
PARTITION BY KEY()
PARTITIONS 2;
```

If there is no primary key but there is a unique key, then the unique key is used for the partitioning key:

```
CREATE TABLE k1 (
  id INT NOT NULL,
  name VARCHAR(20),
  UNIQUE KEY (id)
)
PARTITION BY KEY()
PARTITIONS 2;
```

However, if the unique key column were not defined as **NOT NULL**, then the previous statement would fail.

In both of these cases, the partitioning key is the **id** column, even though it is not shown in the output of **SHOW CREATE TABLE** or in the **PARTITION_EXPRESSION** column of the **INFORMATION_SCHEMA.PARTITIONS** table.

Unlike the case with other partitioning types, columns used for partitioning by **KEY** are not restricted to integer or **NULL** values. For example, the following **CREATE TABLE** statement is valid:

```
CREATE TABLE tm1 (
  s1 CHAR(32) PRIMARY KEY
)
PARTITION BY KEY(s1)
PARTITIONS 10;
```

The preceding statement would *not* be valid, were a different partitioning type to be specified.

Note

In this case, simply using **PARTITION BY KEY()** would also be valid and have the same effect as **PARTITION BY KEY(s1)**, since **s1** is the table's primary key.

For additional information about this issue, see [Section 17.5, “Restrictions and Limitations on Partitioning”](#).

Note

Also beginning with MySQL 5.1.6, tables using the **NDB Cluster** storage engine are implicitly partitioned by **KEY**, again using the table's primary key as the partitioning key. In the event that the Cluster table has no explicit primary key, the “hidden” primary key generated by the **NDB** storage engine for each Cluster table is used as the partitioning key.

Important

For a key-partitioned table using any MySQL storage engine other than **NDB Cluster**, you cannot execute an **ALTER TABLE DROP PRIMARY KEY**, as doing so generates the error **ERROR 1466 (HY000): FIELD IN LIST OF FIELDS FOR PARTITION FUNCTION NOT FOUND IN TABLE**. This is not an issue for MySQL Cluster tables which are partitioned by **KEY**; in such cases, the table is reorganized using the “hidden” primary key as the table's new partitioning key. See [Chapter 16, MySQL Cluster](#).

It is also possible to partition a table by linear key. Here is a simple example:

```
CREATE TABLE tk (
  col1 INT NOT NULL,
  col2 CHAR(5),
```

```
col3 DATE
)
PARTITION BY LINEAR KEY (col1)
PARTITIONS 3;
```

Using **LINEAR** has the same effect on **KEY** partitioning as it does on **HASH** partitioning, with the partition number being derived using a powers-of-two algorithm rather than modulo arithmetic. See [Section 17.2.3.1, “LINEAR HASH Partitioning”](#), for a description of this algorithm and its implications.

17.2.5. Subpartitioning

Subpartitioning — also known as *composite partitioning* — is the further division of each partition in a partitioned table. For example, consider the following **CREATE TABLE** statement:

```
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE( YEAR(purchased) )
SUBPARTITION BY HASH( TO_DAYS(purchased) )
SUBPARTITIONS 2 (
    PARTITION p0 VALUES LESS THAN (1990),
    PARTITION p1 VALUES LESS THAN (2000),
    PARTITION p2 VALUES LESS THAN MAXVALUE
);
```

Table **ts** has 3 **RANGE** partitions. Each of these partitions — **p0**, **p1**, and **p2** — is further divided into 2 subpartitions. In effect, the entire table is divided into $3 * 2 = 6$ partitions. However, due to the action of the **PARTITION BY RANGE** clause, the first 2 of these store only those records with a value less than 1990 in the **purchased** column.

In MySQL 5.1, it is possible to subpartition tables that are partitioned by **RANGE** or **LIST**. Subpartitions may use either **HASH** or **KEY** partitioning. This is also known as *composite partitioning*.

It is also possible to define subpartitions explicitly using **SUBPARTITION** clauses to specify options for individual subpartitions. For example, a more verbose fashion of creating the same table **ts** as shown in the previous example would be:

```
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE( YEAR(purchased) )
SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
    PARTITION p0 VALUES LESS THAN (1990) (
        SUBPARTITION s0,
        SUBPARTITION s1
    ),
    PARTITION p1 VALUES LESS THAN (2000) (
        SUBPARTITION s2,
        SUBPARTITION s3
    ),
    PARTITION p2 VALUES LESS THAN MAXVALUE (
        SUBPARTITION s4,
        SUBPARTITION s5
    )
);
```

Some syntactical items of note:

- Each partition must have the same number of subpartitions.
- If you explicitly define any subpartitions using **SUBPARTITION** on any partition of a partitioned table, you must define them all. In other words, the following statement will fail:

```
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE( YEAR(purchased) )
SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
    PARTITION p0 VALUES LESS THAN (1990) (
        SUBPARTITION s0,
        SUBPARTITION s1
    ),
    PARTITION p1 VALUES LESS THAN (2000),
    PARTITION p2 VALUES LESS THAN MAXVALUE (
        SUBPARTITION s2,
        SUBPARTITION s3
    )
);
```

This statement would still fail even if it included a **SUBPARTITIONS 2** clause.

- Each **SUBPARTITION** clause must include (at a minimum) a name for the subpartition. Otherwise, you may set any desired option for the subpartition or allow it to assume its default setting for that option.
- In MySQL 5.1.7 and earlier, names of subpartitions must be unique within each partition, but do not have to be unique within the table as a whole. Beginning with MySQL 5.1.8, subpartition names must be unique across the entire table. For example, the following **CREATE TABLE** statement is valid in MySQL 5.1.8 and later:

```
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE( YEAR(purchased) )
SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
  PARTITION p0 VALUES LESS THAN (1990) (
    SUBPARTITION s0,
    SUBPARTITION s1
  ),
  PARTITION p1 VALUES LESS THAN (2000) (
    SUBPARTITION s2,
    SUBPARTITION s3
  ),
  PARTITION p2 VALUES LESS THAN MAXVALUE (
    SUBPARTITION s4,
    SUBPARTITION s5
  )
);
```

(The previous statement is also valid for versions of MySQL prior to 5.1.8.)

Subpartitions can be used with especially large tables to distribute data and indexes across many disks. Suppose that you have 6 disks mounted as **/disk0**, **/disk1**, **/disk2**, and so on. Now consider the following example:

```
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE( YEAR(purchased) )
SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
  PARTITION p0 VALUES LESS THAN (1990) (
    SUBPARTITION s0
      DATA DIRECTORY = '/disk0/data'
      INDEX DIRECTORY = '/disk0/idx',
    SUBPARTITION s1
      DATA DIRECTORY = '/disk1/data'
      INDEX DIRECTORY = '/disk1/idx'
  ),
  PARTITION p1 VALUES LESS THAN (2000) (
    SUBPARTITION s2
      DATA DIRECTORY = '/disk2/data'
      INDEX DIRECTORY = '/disk2/idx',
    SUBPARTITION s3
      DATA DIRECTORY = '/disk3/data'
      INDEX DIRECTORY = '/disk3/idx'
  ),
  PARTITION p2 VALUES LESS THAN MAXVALUE (
    SUBPARTITION s4
      DATA DIRECTORY = '/disk4/data'
      INDEX DIRECTORY = '/disk4/idx',
    SUBPARTITION s5
      DATA DIRECTORY = '/disk5/data'
      INDEX DIRECTORY = '/disk5/idx'
  )
);
```

In this case, a separate disk is used for the data and for the indexes of each **RANGE**. Many other variations are possible; another example might be:

```
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE(YEAR(purchased))
SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
  PARTITION p0 VALUES LESS THAN (1990) (
    SUBPARTITION s0a
      DATA DIRECTORY = '/disk0'
      INDEX DIRECTORY = '/disk1',
    SUBPARTITION s0b
      DATA DIRECTORY = '/disk2'
      INDEX DIRECTORY = '/disk3'
  ),
  PARTITION p1 VALUES LESS THAN (2000) (
    SUBPARTITION s1a
      DATA DIRECTORY = '/disk4/data'
      INDEX DIRECTORY = '/disk4/idx',
    SUBPARTITION s1b
      DATA DIRECTORY = '/disk5/data'
      INDEX DIRECTORY = '/disk5/idx'
  ),
  PARTITION p2 VALUES LESS THAN MAXVALUE (
    SUBPARTITION s2a,
```

```

        SUBPARTITION s2b
    );

```

Here, the storage is as follows:

- Rows with **purchased** dates from before 1990 take up a vast amount of space, so are split up 4 ways, with a separate disk dedicated to the data and to the indexes for each of the two subpartitions (**s0a** and **s0b**) making up partition **p0**. In other words:
 - The data for subpartition **s0a** is stored on **/disk0**.
 - The indexes for subpartition **s0a** are stored on **/disk1**.
 - The data for subpartition **s0b** is stored on **/disk2**.
 - The indexes for subpartition **s0b** are stored on **/disk3**.
- Rows containing dates ranging from 1990 to 1999 (partition **p1**) do not require as much room as those from before 1990. These are split between 2 disks (**/disk4** and **/disk5**) rather than 4 disks as with the legacy records stored in **p0**:
 - Data and indexes belonging to **p1**'s first subpartition (**s1a**) are stored on **/disk4** — the data in **/disk4/data**, and the indexes in **/disk4/idx**.
 - Data and indexes belonging to **p1**'s second subpartition (**s1b**) are stored on **/disk5** — the data in **/disk5/data**, and the indexes in **/disk5/idx**.
- Rows reflecting dates from the year 2000 to the present (partition **p2**) do not take up as much space as required by either of the two previous ranges. Currently, it is sufficient to store all of these in the default location.

In future, when the number of purchases for the decade beginning with the year 2000 grows to a point where the default location no longer provides sufficient space, the corresponding rows can be moved using an **ALTER TABLE ... REORGANIZE PARTITION** statement. See [Section 17.3, “Partition Management”](#), for an explanation of how this can be done.

Beginning with MySQL 5.1.18, the **DATA DIRECTORY** and **INDEX DIRECTORY** options are disallowed when the **NO_DIR_IN_CREATE** server SQL mode is in effect. This is true for partitions and subpartitions.

17.2.6. How MySQL Partitioning Handles **NULL** Values

Partitioning in MySQL does nothing to disallow **NULL** as the value of a partitioning expression, whether it is a column value or the value of a user-supplied expression. Even though it is permitted to use **NULL** as the value of an expression that must otherwise yield an integer, it is important to keep in mind that **NULL** is not a number. Beginning version 5.1.8, MySQL Partitioning treats **NULL** as being less than any non-**NULL** value, just as **ORDER BY** does.

Because of this, this treatment of **NULL** varies between partitioning of different types, and may produce behavior which you do not expect if you are not prepared for it. This being the case, we discuss in this section how each MySQL partitioning types handles **NULL** values when determining the partition in which a row should be stored, and provide examples for each.

If you insert a row into a table partitioned by **RANGE** such that the column value used to determine the partition is **NULL**, the row is inserted into the lowest partition. For example, consider these two tables, created and populated as follows:

```

mysql> CREATE TABLE t1 (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY RANGE(c1) (
->   PARTITION p0 VALUES LESS THAN (0),
->   PARTITION p1 VALUES LESS THAN (10),
->   PARTITION p2 VALUES LESS THAN MAXVALUE
-> );
Query OK, 0 rows affected (0.09 sec)

mysql> CREATE TABLE t1 (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY RANGE(c1) (
->   PARTITION p0 VALUES LESS THAN (-5),
->   PARTITION p1 VALUES LESS THAN (0),
->   PARTITION p1 VALUES LESS THAN (10),

```

```

-> PARTITION p2 VALUES LESS THAN MAXVALUE
-> );
Query OK, 0 rows affected (0.09 sec)

mysql> INSERT INTO t1 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM t1;
+-----+-----+
| id    | name  |
+-----+-----+
| NULL  | mothra |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT * FROM t2;
+-----+-----+
| id    | name  |
+-----+-----+
| NULL  | mothra |
+-----+-----+
1 row in set (0.00 sec)

```

You can see which partitions the rows are stored in by inspecting the filesystem and comparing the sizes of the `.MYD` files corresponding to the partitions:

```

/var/lib/mysql/test> ls -l *.MYD
-rw-rw---- 1 mysql mysql 20 2006-03-10 03:27 t1#P#p0.MYD
-rw-rw---- 1 mysql mysql 0 2006-03-10 03:17 t1#P#p1.MYD
-rw-rw---- 1 mysql mysql 0 2006-03-10 03:17 t1#P#p2.MYD
-rw-rw---- 1 mysql mysql 20 2006-03-10 03:27 t2#P#p0.MYD
-rw-rw---- 1 mysql mysql 0 2006-03-10 03:17 t2#P#p1.MYD
-rw-rw---- 1 mysql mysql 0 2006-03-10 03:17 t2#P#p2.MYD
-rw-rw---- 1 mysql mysql 0 2006-03-10 03:17 t2#P#p3.MYD

```

Partition files are named according to the format `table_name#P#partition_name.extension`, so that `t1#P#p0.MYD` is the file in which data belonging to partition `p0` of table `t1` is stored.

Note

Prior to MySQL 5.1.5, these files would have been named `t1_p0.MYD` and `t2_p0.MYD`, respectively. See [Section C.1.24, “Changes in release 5.1.6 \(01 February 2006\)”](#) and [Bug#13437](#) for information regarding how this change impacts upgrades.

You can also demonstrate that these rows were stored in the lowest partition of the each table by dropping these partitions, and then re-running the `SELECT` statements:

```

mysql> ALTER TABLE t1 DROP PARTITION p0;
Query OK, 0 rows affected (0.16 sec)

mysql> ALTER TABLE t2 DROP PARTITION p0;
Query OK, 0 rows affected (0.16 sec)

mysql> SELECT * FROM t1;
Empty set (0.00 sec)

mysql> SELECT * FROM t2;
Empty set (0.00 sec)

```

(For more information on `ALTER TABLE ... DROP PARTITION`, see [Section 12.1.4, “ALTER TABLE Syntax”](#).)

Such treatment also holds true for partitioning expressions that use SQL functions. Suppose that we have a table such as this one:

```

CREATE TABLE tndate (
  id INT,
  dt DATE
)
PARTITION BY RANGE( YEAR(dt) ) (
  PARTITION p0 VALUES LESS THAN (1990),
  PARTITION p1 VALUES LESS THAN (2000),
  PARTITION p2 VALUES LESS THAN MAXVALUE
);

```

As with other MySQL functions, `YEAR(NULL)` returns `NULL`. A row with a `dt` column value of `NULL` is treated as though the partitioning expression evaluated to a value less than any other value, and so is inserted into partition `p0`.

A table that is partitioned by **LIST** admits **NULL** values if and only if one of its partitions is defined using that value-list that contains **NULL**. The converse of this is that a table partitioned by **LIST** which does not explicitly use **NULL** in a value list rejects rows resulting in a **NULL** value for the partitioning expression, as shown in this example:

```
mysql> CREATE TABLE ts1 (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY LIST(c1) (
->   PARTITION p0 VALUES IN (0, 3, 6),
->   PARTITION p1 VALUES IN (1, 4, 7),
->   PARTITION p2 VALUES IN (2, 5, 8)
-> );
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO ts1 VALUES (9, 'mothra');
ERROR 1504 (HY000): TABLE HAS NO PARTITION FOR VALUE 9

mysql> INSERT INTO ts1 VALUES (NULL, 'mothra');
ERROR 1504 (HY000): TABLE HAS NO PARTITION FOR VALUE NULL
```

Only rows having a **c1** value between 0 and 8 inclusive can be inserted into **ts1**. **NULL** falls outside this range, just like the number 9. We can create tables **ts2** and **ts3** having value lists containing **NULL**, as shown here:

```
mysql> CREATE TABLE ts2 (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY LIST(c1) (
->   PARTITION p0 VALUES IN (0, 3, 6),
->   PARTITION p1 VALUES IN (1, 4, 7),
->   PARTITION p2 VALUES IN (2, 5, 8),
->   PARTITION p3 VALUES IN (NULL)
-> );
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE ts3 (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY LIST(c1) (
->   PARTITION p0 VALUES IN (0, 3, 6),
->   PARTITION p1 VALUES IN (1, 4, 7, NULL),
->   PARTITION p2 VALUES IN (2, 5, 8)
-> );
Query OK, 0 rows affected (0.01 sec)
```

When defining value lists for partitioning, you can treat **NULL** just as you would any other value, and so **VALUES IN (NULL)** and **VALUES IN (1, 4, 7, NULL)** are both valid (as are **VALUES IN (1, NULL, 4, 7)**, **VALUES IN (NULL, 1, 4, 7)**, and so on). You can insert a row having **NULL** for column **c1** into each of the tables **ts2** and **ts3**:

```
mysql> INSERT INTO ts2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO ts3 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)
```

By inspecting the filesystem, you can verify that the first of these statements inserted a new row into partition **p3** of table **ts2**, and that the second statement inserted a new row into partition **p1** of table **ts3**:

```
/var/lib/mysql/test> ls -l ts2*.MYD
-rw-rw---- 1 mysql mysql 0 2006-03-10 10:35 ts2#P#p0.MYD
-rw-rw---- 1 mysql mysql 0 2006-03-10 10:35 ts2#P#p1.MYD
-rw-rw---- 1 mysql mysql 0 2006-03-10 10:35 ts2#P#p2.MYD
-rw-rw---- 1 mysql mysql 20 2006-03-10 10:35 ts2#P#p3.MYD

/var/lib/mysql/test> ls -l ts3*.MYD
-rw-rw---- 1 mysql mysql 0 2006-03-10 10:36 ts3#P#p0.MYD
-rw-rw---- 1 mysql mysql 20 2006-03-10 10:36 ts3#P#p1.MYD
-rw-rw---- 1 mysql mysql 0 2006-03-10 10:36 ts3#P#p2.MYD
```

As in earlier examples, we assume the use of the **bash** shell on a Unix operating system for listing files; use whatever your platform provides in this regard. For example, if you are using a DOS shell on a Windows operating system, the equivalent for the last listing might be obtained by running the command **dir ts3*.MYD** in the directory **C:\Program Files\MySQL\MySQL Server 5.1\data\test**.

As shown earlier in this section, you can also verify which partitions were used for storing the values by deleting them and then per-

forming a `SELECT`.

`NULL` is handled somewhat differently for tables partitioned by `HASH` or `KEY`. In these cases, any partition expression that yields a `NULL` value is treated as though its return value were zero. We can verify this behavior by examining the effects on the filesystem of creating a table partitioned by `HASH` and populating it with a record containing appropriate values. Suppose that you have a table `th`, created in the `test` database, using this statement:

```
mysql> CREATE TABLE th (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY HASH(c1)
-> PARTITIONS 2;
Query OK, 0 rows affected (0.00 sec)
```

Assuming an RPM installation of MySQL on Linux, this statement creates two `.MYD` files in `/var/lib/mysql/test`, which can be viewed in the `bash` shell as follows:

```
/var/lib/mysql/test> ls th*.MYD -l
-rw-rw---- 1 mysql mysql 0 2005-11-04 18:41 th#P#p0.MYD
-rw-rw---- 1 mysql mysql 0 2005-11-04 18:41 th#P#p1.MYD
```

Note that the size of each file is 0 bytes. Now insert a row into `th` whose `c1` column value is `NULL`, and verify that this row was inserted:

```
mysql> INSERT INTO th VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM th;
+-----+-----+
| c1    | c2    |
+-----+-----+
| NULL  | mothra |
+-----+-----+
1 row in set (0.01 sec)
```

Recall that for any integer `N`, the value of `NULL MOD N` is always `NULL`. For tables that are partitioned by `HASH` or `KEY`, this result is treated for determining the correct partition as `0`. Returning to the system shell (still assuming `bash` for this purpose), we can see that the value was inserted into the first partition (named `p0` by default) by listing the data files once again:

```
var/lib/mysql/test> ls *.MYD -l
-rw-rw---- 1 mysql mysql 20 2005-11-04 18:44 th#P#p0.MYD
-rw-rw---- 1 mysql mysql 0 2005-11-04 18:41 th#P#p1.MYD
```

You can see that the `INSERT` statement modified only the file `th#P#p0.MYD` (increasing its size on disk), without affecting the other data file.

Important

Prior to MySQL 5.1.8, `RANGE` partitioning treated a partitioning expression value of `NULL` as a zero with respect to determining placement (the only way to circumvent this was to design tables so as not to allow nulls, usually by declaring columns `NOT NULL`). If you have a `RANGE` partitioning scheme that depends on this earlier behavior, you will need to re-implement it when upgrading to MySQL 5.1.8 or later.

17.3. Partition Management

MySQL 5.1 provides a number of ways to modify partitioned tables. It is possible to add, drop, redefine, merge, or split existing partitions. All of these actions can be carried out using the partitioning extensions to the `ALTER TABLE` command (see [Section 12.1.4, “ALTER TABLE Syntax”](#), for syntax definitions). There are also ways to obtain information about partitioned tables and partitions. We discuss these topics in the sections that follow.

- For information about partition management in tables partitioned by `RANGE` or `LIST`, see [Section 17.3.1, “Management of RANGE and LIST Partitions”](#).
- For a discussion of managing `HASH` and `KEY` partitions, see [Section 17.3.2, “Management of HASH and KEY Partitions”](#).
- See [Section 17.3.4, “Obtaining Information About Partitions”](#), for a discussion of mechanisms provided in MySQL 5.1 for obtaining

information about partitioned tables and partitions.

- For a discussion of performing maintenance operations on partitions, see [Section 17.3.3, “Maintenance of Partitions”](#).

Note

In MySQL 5.1, all partitions of a partitioned table must have the same number of subpartitions, and it is not possible to change the subpartitioning once the table has been created.

The statement `ALTER TABLE ... PARTITION BY ...` is available and is functional beginning with MySQL 5.1.6; previously in MySQL 5.1, this was accepted as valid syntax, but the statement did nothing.

To change a table's partitioning scheme, it is necessary only to use the `ALTER TABLE` command with a *partition_options* clause. This clause has the same syntax as that as used with `CREATE TABLE` for creating a partitioned table, and always begins with the keywords `PARTITION BY`. For example, suppose that you have a table partitioned by range using the following `CREATE TABLE` statement:

```
CREATE TABLE trb3 (id INT, name VARCHAR(50), purchased DATE)
PARTITION BY RANGE( YEAR(purchased) ) (
    PARTITION p0 VALUES LESS THAN (1990),
    PARTITION p1 VALUES LESS THAN (1995),
    PARTITION p2 VALUES LESS THAN (2000),
    PARTITION p3 VALUES LESS THAN (2005)
);
```

To repartition this table so that it is partitioned by key into two partitions using the `id` column value as the basis for the key, you can use this statement:

```
ALTER TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;
```

This has the same effect on the structure of the table as dropping the table and re-creating it using `CREATE TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;`.

Important

In MySQL 5.1.7 and earlier MySQL 5.1 releases, `ALTER TABLE ... ENGINE = ...` removed all partitioning from the affected table. Beginning with MySQL 5.1.8, this statement changes only the storage engine used by the table, and leaves the table's partitioning scheme intact. As of MySQL 5.1.8, use `ALTER TABLE ... REMOVE PARTITIONING` to remove a table's partitioning. See [Section 12.1.4, “ALTER TABLE Syntax”](#).

17.3.1. Management of RANGE and LIST Partitions

Range and list partitions are very similar with regard to how the adding and dropping of partitions are handled. For this reason we discuss the management of both sorts of partitioning in this section. For information about working with tables that are partitioned by hash or key, see [Section 17.3.2, “Management of HASH and KEY Partitions”](#). Dropping a `RANGE` or `LIST` partition is more straightforward than adding one, so we discuss this first.

Dropping a partition from a table that is partitioned by either `RANGE` or by `LIST` can be accomplished using the `ALTER TABLE` statement with a `DROP PARTITION` clause. Here is a very basic example, which supposes that you have already created a table which is partitioned by range and then populated with 10 records using the following `CREATE TABLE` and `INSERT` statements:

```
mysql> CREATE TABLE tr (id INT, name VARCHAR(50), purchased DATE)
-> PARTITION BY RANGE( YEAR(purchased) ) (
-> PARTITION p0 VALUES LESS THAN (1990),
-> PARTITION p1 VALUES LESS THAN (1995),
-> PARTITION p2 VALUES LESS THAN (2000),
-> PARTITION p3 VALUES LESS THAN (2005)
-> );
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO tr VALUES
-> (1, 'desk organiser', '2003-10-15'),
-> (2, 'CD player', '1993-11-05'),
-> (3, 'TV set', '1996-03-10'),
-> (4, 'bookcase', '1982-01-10'),
-> (5, 'exercise bike', '2004-05-09'),
-> (6, 'sofa', '1987-06-05'),
-> (7, 'popcorn maker', '2001-11-22'),
-> (8, 'aquarium', '1992-08-04'),
-> (9, 'study desk', '1984-09-16'),
```

```
-> (10, 'lava lamp', '1998-12-25');
Query OK, 10 rows affected (0.01 sec)
```

You can see which items should have been inserted into partition `p2` as shown here:

```
mysql> SELECT * FROM tr
-> WHERE purchased BETWEEN '1995-01-01' AND '1999-12-31';
+-----+-----+-----+
| id | name | purchased |
+-----+-----+-----+
| 3 | TV set | 1996-03-10 |
| 10 | lava lamp | 1998-12-25 |
+-----+-----+-----+
2 rows in set (0.00 sec)
```

To drop the partition named `p2`, execute the following command:

```
mysql> ALTER TABLE tr DROP PARTITION p2;
Query OK, 0 rows affected (0.03 sec)
```

Note: In MySQL 5.1, the `NDBCLUSTER` storage engine does not support `ALTER TABLE ... DROP PARTITION`. It does, however, support the other partitioning-related extensions to `ALTER TABLE` that are described in this chapter.

It is very important to remember that, *when you drop a partition, you also delete all the data that was stored in that partition*. You can see that this is the case by re-running the previous `SELECT` query:

```
mysql> SELECT * FROM tr WHERE purchased
-> BETWEEN '1995-01-01' AND '1999-12-31';
Empty set (0.00 sec)
```

Because of this, the requirement was added in MySQL 5.1.10 that you have the `DROP` privilege for a table before you can execute `ALTER TABLE ... DROP PARTITION` on that table.

If you wish to drop all data from all partitions while preserving the table definition and its partitioning scheme, use the `TRUNCATE TABLE` command. (See [Section 12.2.9, “TRUNCATE Syntax”](#).)

If you intend to change the partitioning of a table *without* losing data, use `ALTER TABLE ... REORGANIZE PARTITION` instead. See below or in [Section 12.1.4, “ALTER TABLE Syntax”](#), for information about `REORGANIZE PARTITION`.

If you now execute a `SHOW CREATE TABLE` command, you can see how the partitioning makeup of the table has been changed:

```
mysql> SHOW CREATE TABLE tr\G
***** 1. row *****
Table: tr
Create Table: CREATE TABLE `tr` (
  `id` int(11) default NULL,
  `name` varchar(50) default NULL,
  `purchased` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE ( YEAR(purchased) ) (
  PARTITION p0 VALUES LESS THAN (1990) ENGINE = MyISAM,
  PARTITION p1 VALUES LESS THAN (1995) ENGINE = MyISAM,
  PARTITION p3 VALUES LESS THAN (2005) ENGINE = MyISAM
)
1 row in set (0.01 sec)
```

When you insert new rows into the changed table with `purchased` column values between `'1995-01-01'` and `'2004-12-31'` inclusive, those rows will be stored in partition `p3`. You can verify this as follows:

```
mysql> INSERT INTO tr VALUES (11, 'pencil holder', '1995-07-12');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM tr WHERE purchased
-> BETWEEN '1995-01-01' AND '2004-12-31';
+-----+-----+-----+
| id | name | purchased |
+-----+-----+-----+
| 11 | pencil holder | 1995-07-12 |
| 1 | desk organiser | 2003-10-15 |
| 5 | exercise bike | 2004-05-09 |
| 7 | popcorn maker | 2001-11-22 |
+-----+-----+-----+
4 rows in set (0.00 sec)

mysql> ALTER TABLE tr DROP PARTITION p3;
Query OK, 0 rows affected (0.03 sec)
```

```
mysql> SELECT * FROM tr WHERE purchased
-> BETWEEN '1995-01-01' AND '2004-12-31';
Empty set (0.00 sec)
```

Note that the number of rows dropped from the table as a result of `ALTER TABLE ... DROP PARTITION` is not reported by the server as it would be by the equivalent `DELETE` query.

Dropping `LIST` partitions uses exactly the same `ALTER TABLE ... DROP PARTITION` syntax as used for dropping `RANGE` partitions. However, there is one important difference in the effect this has on your use of the table afterward: You can no longer insert into the table any rows having any of the values that were included in the value list defining the deleted partition. (See [Section 17.2.2](#), “`LIST` Partitioning”, for an example.)

To add a new range or list partition to a previously partitioned table, use the `ALTER TABLE ... ADD PARTITION` statement. For tables which are partitioned by `RANGE`, this can be used to add a new range to the end of the list of existing partitions. For example, suppose that you have a partitioned table containing membership data for your organisation, which is defined as follows:

```
CREATE TABLE members (
  id INT,
  fname VARCHAR(25),
  lname VARCHAR(25),
  dob DATE
)
PARTITION BY RANGE( YEAR(dob) ) (
  PARTITION p0 VALUES LESS THAN (1970),
  PARTITION p1 VALUES LESS THAN (1980),
  PARTITION p2 VALUES LESS THAN (1990)
);
```

Suppose further that the minimum age for members is 16. As the calendar approaches the end of 2005, you realize that you will soon be admitting members who were born in 1990 (and later in years to come). You can modify the `members` table to accommodate new members born in the years 1990-1999 as shown here:

```
ALTER TABLE ADD PARTITION (PARTITION p3 VALUES LESS THAN (2000));
```

Important

With tables that are partitioned by range, you can use `ADD PARTITION` to add new partitions to the high end of the partitions list only. Trying to add a new partition in this manner between or before existing partitions will result in an error as shown here:

```
mysql> ALTER TABLE members
> ADD PARTITION (
> PARTITION p3 VALUES LESS THAN (1960));
ERROR 1463 (HY000): VALUES LESS THAN value must be strictly »
increasing for each partition
```

In a similar fashion, you can add new partitions to a table that is partitioned by `LIST`. For example, given a table defined like so:

```
CREATE TABLE tt (
  id INT,
  data INT
)
PARTITION BY LIST(data) (
  PARTITION p0 VALUES IN (5, 10, 15),
  PARTITION p1 VALUES IN (6, 12, 18)
);
```

You can add a new partition in which to store rows having the `data` column values `7`, `14`, and `21` as shown:

```
ALTER TABLE tt ADD PARTITION (PARTITION p2 VALUES IN (7, 14, 21));
```

Note that you *cannot* add a new `LIST` partition encompassing any values that are already included in the value list of an existing partition. If you attempt to do so, an error will result:

```
mysql> ALTER TABLE tt ADD PARTITION
> (PARTITION np VALUES IN (4, 8, 12));
ERROR 1465 (HY000): Multiple definition of same constant »
in list partitioning
```

Because any rows with the `data` column value `12` have already been assigned to partition `p1`, you cannot create a new partition on table `tt` that includes `12` in its value list. To accomplish this, you could drop `p1`, and add `np` and then a new `p1` with a modified definition. However, as discussed earlier, this would result in the loss of all data stored in `p1` — and it is often the case that this is not what you really want to do. Another solution might appear to be to make a copy of the table with the new partitioning and to copy the data into it using `CREATE TABLE ... SELECT ...`, then drop the old table and rename the new one, but this could be very time-consuming when dealing with a large amounts of data. This also might not be feasible in situations where high availability is a requirement.

Beginning with MySQL 5.1.6, you can add multiple partitions in a single `ALTER TABLE ... ADD PARTITION` statement as shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  hired DATE NOT NULL
)
PARTITION BY RANGE( YEAR(hired) ) (
  PARTITION p1 VALUES LESS THAN (1991),
  PARTITION p2 VALUES LESS THAN (1996),
  PARTITION p3 VALUES LESS THAN (2001),
  PARTITION p4 VALUES LESS THAN (2005)
);

ALTER TABLE employees ADD PARTITION (
  PARTITION p5 VALUES LESS THAN (2010),
  PARTITION p6 VALUES LESS THAN MAXVALUE
);
```

Fortunately, MySQL's partitioning implementation provides ways to redefine partitions without losing data. Let us look first at a couple of simple examples involving `RANGE` partitioning. Recall the `members` table which is now defined as shown here:

```
mysql> SHOW CREATE TABLE members\G
***** 1. row *****
Table: members
Create Table: CREATE TABLE `members` (
  `id` int(11) default NULL,
  `fname` varchar(25) default NULL,
  `lname` varchar(25) default NULL,
  `dob` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE ( YEAR(dob) ) (
  PARTITION p0 VALUES LESS THAN (1970) ENGINE = MyISAM,
  PARTITION p1 VALUES LESS THAN (1980) ENGINE = MyISAM,
  PARTITION p2 VALUES LESS THAN (1990) ENGINE = MyISAM,
  PARTITION p3 VALUES LESS THAN (2000) ENGINE = MyISAM
)
```

Suppose that you would like to move all rows representing members born before 1960 into a separate partition. As we have already seen, this cannot be done using `ALTER TABLE ... ADD PARTITION`. However, you can use another partition-related extension to `ALTER TABLE` in order to accomplish this:

```
ALTER TABLE members REORGANIZE PARTITION p0 INTO (
  PARTITION s0 VALUES LESS THAN (1960),
  PARTITION s1 VALUES LESS THAN (1970)
);
```

In effect, this command splits partition `p0` into two new partitions `s0` and `s1`. It also moves the data that was stored in `p0` into the new partitions according to the rules embodied in the two `PARTITION ... VALUES ...` clauses, so that `s0` contains only those records for which `YEAR(dob)` is less than 1960 and `s1` contains those rows in which `YEAR(dob)` is greater than or equal to 1960 but less than 1970.

A `REORGANIZE PARTITION` clause may also be used for merging adjacent partitions. You can return the `members` table to its previous partitioning as shown here:

```
ALTER TABLE members REORGANIZE PARTITION s0,s1 INTO (
  PARTITION p0 VALUES LESS THAN (1970)
);
```

No data is lost in splitting or merging partitions using `REORGANIZE PARTITION`. In executing the above statement, MySQL moves all of the records that were stored in partitions `s0` and `s1` into partition `p0`.

The general syntax for `REORGANIZE PARTITION` is:

```
ALTER TABLE tbl_name
  REORGANIZE PARTITION partition_list
  INTO (partition_definitions);
```

Here, *tbl_name* is the name of the partitioned table, and *partition_list* is a comma-separated list of names of one or more existing partitions to be changed. *partition_definitions* is a comma-separated list of new partition definitions, which follow the same rules as for the *partition_definitions* list used in [CREATE TABLE](#) (see [Section 12.1.10, “CREATE TABLE Syntax”](#)). It should be noted that you are not limited to merging several partitions into one, or to splitting one partition into many, when using [REORGANIZE PARTITION](#). For example, you can reorganize all four partitions of the `members` table into two, as follows:

```
ALTER TABLE members REORGANIZE PARTITION p0,p1,p2,p3 INTO (
  PARTITION m0 VALUES LESS THAN (1980),
  PARTITION m1 VALUES LESS THAN (2000)
);
```

You can also use [REORGANIZE PARTITION](#) with tables that are partitioned by [LIST](#). Let us return to the problem of adding a new partition to the list-partitioned `tt` table and failing because the new partition had a value that was already present in the value-list of one of the existing partitions. We can handle this by adding a partition that contains only non-conflicting values, and then reorganizing the new partition and the existing one so that the value which was stored in the existing one is now moved to the new one:

```
ALTER TABLE tt ADD PARTITION (PARTITION np VALUES IN (4, 8));
ALTER TABLE tt REORGANIZE PARTITION p1,np INTO (
  PARTITION p1 VALUES IN (6, 18),
  PARTITION np VALUES in (4, 8, 12)
);
```

Here are some key points to keep in mind when using [ALTER TABLE ... REORGANIZE PARTITION](#) to repartition tables that are partitioned by [RANGE](#) or [LIST](#):

- The [PARTITION](#) clauses used to determine the new partitioning scheme are subject to the same rules as those used with a [CREATE TABLE](#) statement.

Most importantly, you should remember that the new partitioning scheme cannot have any overlapping ranges (applies to tables partitioned by [RANGE](#)) or sets of values (when reorganizing tables partitioned by [LIST](#)).

Note

Prior to MySQL 5.1.4, you could not reuse the names of existing partitions in the `INTO` clause, even when those partitions were being dropped or redefined. See [Section C.1.26, “Changes in release 5.1.4 \(21 December 2005\)”](#), for more information.

- The combination of partitions in the *partition_definitions* list should account for the same range or set of values overall as the combined partitions named in the *partition_list*.

For instance, in the `members` table used as an example in this section, partitions `p1` and `p2` together cover the years 1980 through 1999. Therefore, any reorganization of these two partitions should cover the same range of years overall.

- For tables partitioned by [RANGE](#), you can reorganize only adjacent partitions; you cannot skip over range partitions.

For instance, you could not reorganize the `members` table used as an example in this section using a statement beginning with `ALTER TABLE members REORGANIZE PARTITION p0,p2 INTO ...` because `p0` covers the years prior to 1970 and `p2` the years from 1990 through 1999 inclusive, and thus the two are not adjacent partitions.

- You cannot use [REORGANIZE PARTITION](#) to change the table's partitioning type; that is, you cannot (for example) change [RANGE](#) partitions to [HASH](#) partitions or *vice versa*. You also cannot use this command to change the partitioning expression or column. To accomplish either of these tasks without dropping and re-creating the table, you can use [ALTER TABLE ... PARTITION BY ...](#). For example:

```
ALTER TABLE members
  PARTITION BY HASH( YEAR(dob) )
  PARTITIONS 8;
```

17.3.2. Management of [HASH](#) and [KEY](#) Partitions

Tables which are partitioned by hash or by key are very similar to one another with regard to making changes in a partitioning setup, and both differ in a number of ways from tables which have been partitioned by range or list. For that reason, this section addresses the modification of tables partitioned by hash or by key only. For a discussion of adding and dropping of partitions of tables that are partitioned by range or list, see [Section 17.3.1, “Management of RANGE and LIST Partitions”](#).

You cannot drop partitions from tables that are partitioned by [HASH](#) or [KEY](#) in the same way that you can from tables that are partitioned by [RANGE](#) or [LIST](#). However, you can merge [HASH](#) or [KEY](#) partitions using the [ALTER TABLE ... COALESCE PARTITION](#) command. For example, suppose that you have a table containing data about clients, which is divided into twelve partitions. The `clients` table is defined as shown here:

```
CREATE TABLE clients (
  id INT,
  fname VARCHAR(30),
  lname VARCHAR(30),
  signed DATE
)
PARTITION BY HASH( MONTH(signed) )
PARTITIONS 12;
```

To reduce the number of partitions from twelve to eight, execute the following [ALTER TABLE](#) command:

```
mysql> ALTER TABLE clients COALESCE PARTITION 4;
Query OK, 0 rows affected (0.02 sec)
```

[COALESCE](#) works equally well with tables that are partitioned by [HASH](#), [KEY](#), [LINEAR HASH](#), or [LINEAR KEY](#). Here is an example similar to the previous one, differing only in that the table is partitioned by [LINEAR KEY](#):

```
mysql> CREATE TABLE clients_lk (
->   id INT,
->   fname VARCHAR(30),
->   lname VARCHAR(30),
->   signed DATE
-> )
-> PARTITION BY LINEAR KEY(signed)
-> PARTITIONS 12;
Query OK, 0 rows affected (0.03 sec)

mysql> ALTER TABLE clients_lk COALESCE PARTITION 4;
Query OK, 0 rows affected (0.06 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

Note that the number following [COALESCE PARTITION](#) is the number of partitions to merge into the remainder — in other words, it is the number of partitions to remove from the table.

If you attempt to remove more partitions than the table has, the result is an error like the one shown:

```
mysql> ALTER TABLE clients COALESCE PARTITION 18;
ERROR 1478 (HY000): Cannot remove all partitions, use DROP TABLE instead
```

To increase the number of partitions for the `clients` table from 12 to 18, use [ALTER TABLE ... ADD PARTITION](#) as shown here:

```
ALTER TABLE clients ADD PARTITION PARTITIONS 6;
```

17.3.3. Maintenance of Partitions

A number of partitioning maintenance tasks can be carried out in MySQL 5.1. MySQL does not support the commands [CHECK TABLE](#), [OPTIMIZE TABLE](#), [ANALYZE TABLE](#), or [REPAIR TABLE](#) for partitioned tables. Instead, you can use a number of extensions to [ALTER TABLE](#) which were implemented in MySQL 5.1.5. These can be used for performing operations of this type on one or more partitions directly, as described in the following list:

- **Rebuilding partitions.** Rebuilds the partition; this has the same effect as dropping all records stored in the partition, then reinserting them. This can be useful for purposes of defragmentation.

Example:

```
ALTER TABLE t1 REBUILD PARTITION p0, p1;
```

- **Optimizing partitions.** If you have deleted a large number of rows from a partition or if you have made many changes to a partitioned table with variable-length rows (that is, having [VARCHAR](#), [BLOB](#), or [TEXT](#) columns), you can use [ALTER TABLE ... OPTIMIZE PARTITION](#) to reclaim any unused space and to defragment the partition data file.

Example:

```
ALTER TABLE t1 OPTIMIZE PARTITION p0, p1;
```

Using [OPTIMIZE PARTITION](#) on a given partition is equivalent to running [CHECK PARTITION](#), [ANALYZE PARTITION](#), and [REPAIR PARTITION](#) on that partition.

- **Analyzing partitions.** This reads and stores the key distributions for partitions.

Example:

```
ALTER TABLE t1 ANALYZE PARTITION p3;
```

- **Repairing partitions.** This repairs corrupted partitions.

Example:

```
ALTER TABLE t1 REPAIR PARTITION p0,p1;
```

- **Checking partitions.** You can check partitions for errors in much the same way that you can use [CHECK TABLE](#) with non-partitioned tables.

Example:

```
ALTER TABLE trb3 CHECK PARTITION p1;
```

This command will tell you if the data or indexes in partition [p1](#) of table [t1](#) are corrupted. If this is the case, use [ALTER TABLE ... REPAIR PARTITION](#) to repair the partition.

You can also use the [mysqlcheck](#) or [myisamchk](#) utility to accomplish these tasks, operating on the separate [.MYI](#) files generated by partitioning a table. See [Section 7.12, “mysqlcheck — A Table Maintenance and Repair Program”](#).

17.3.4. Obtaining Information About Partitions

This section discusses obtaining information about existing partitions, which can be done in a number of ways. These include:

- Using the [SHOW CREATE TABLE](#) statement to view the partitioning clauses used in creating a partitioned table.
- Using the [SHOW TABLE STATUS](#) statement to determine whether a table is partitioned.
- Querying the [INFORMATION_SCHEMA.PARTITIONS](#) table.
- Using the statement [EXPLAIN PARTITIONS SELECT](#) to see which partitions are used by a given [SELECT](#).

As discussed elsewhere in this chapter, [SHOW CREATE TABLE](#) includes in its output the [PARTITION BY](#) clause used to create a partitioned table. For example:

```
mysql> SHOW CREATE TABLE trb3\G
***** 1. row *****
      Table: trb3
Create Table: CREATE TABLE `trb3` (
  `id` int(11) default NULL,
  `name` varchar(50) default NULL,
  `purchased` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE (YEAR(purchased)) (
  PARTITION p0 VALUES LESS THAN (1990) ENGINE = MyISAM,
  PARTITION p1 VALUES LESS THAN (1995) ENGINE = MyISAM,
  PARTITION p2 VALUES LESS THAN (2000) ENGINE = MyISAM,
  PARTITION p3 VALUES LESS THAN (2005) ENGINE = MyISAM
)
```

1 row in set (0.00 sec)

Note

In early MySQL 5.1 releases, the `PARTITIONS` clause was not shown for tables partitioned by `HASH` or `KEY`. This issue was fixed in MySQL 5.1.6.

`SHOW TABLE STATUS` works with partitioned tables. Beginning with MySQL 5.1.9, its output is the same as that for non-partitioned tables, except that the `Create_options` column contains the string `partitioned`. In MySQL 5.1.8 and earlier, the `Engine` column always contained the value `PARTITION`; beginning with MySQL 5.1.9, this column contains the name of the storage engine used by all partitions of the table. (See [Section 12.5.4.28, “SHOW TABLE STATUS Syntax”](#), for more information about this command.)

You can also obtain information about partitions from `INFORMATION_SCHEMA`, which contains a `PARTITIONS` table. See [Section 23.19, “The INFORMATION_SCHEMA PARTITIONS Table”](#).

Beginning with MySQL 5.1.5, it is possible to determine which partitions of a partitioned table are involved in a given `SELECT` query using `EXPLAIN PARTITIONS`. The `PARTITIONS` keyword adds a `partitions` column to the output of `EXPLAIN` listing the partitions from which records would be matched by the query.

Suppose that you have a table `trb1` defined and populated as follows:

```
CREATE TABLE trb1 (id INT, name VARCHAR(50), purchased DATE)
PARTITION BY RANGE(id)
(
    PARTITION p0 VALUES LESS THAN (3),
    PARTITION p1 VALUES LESS THAN (7),
    PARTITION p2 VALUES LESS THAN (9),
    PARTITION p3 VALUES LESS THAN (11)
);

INSERT INTO trb1 VALUES
(1, 'desk organiser', '2003-10-15'),
(2, 'CD player', '1993-11-05'),
(3, 'TV set', '1996-03-10'),
(4, 'bookcase', '1982-01-10'),
(5, 'exercise bike', '2004-05-09'),
(6, 'sofa', '1987-06-05'),
(7, 'popcorn maker', '2001-11-22'),
(8, 'aquarium', '1992-08-04'),
(9, 'study desk', '1984-09-16'),
(10, 'lava lamp', '1998-12-25');
```

You can see which partitions are used in a query such as `SELECT * FROM trb1;`, as shown here:

```
mysql> EXPLAIN PARTITIONS SELECT * FROM trb1\G
***** 1. row *****
      id: 1
    select_type: SIMPLE
        table: trb1
    partitions: p0,p1,p2,p3
         type: ALL
possible_keys: NULL
         key: NULL
      key_len: NULL
         ref: NULL
        rows: 10
      Extra: Using filesort
```

In this case, all four partitions are searched. However, when a limiting condition making use of the partitioning key is added to the query, you can see that only those partitions containing matching values are scanned, as shown here:

```
mysql> EXPLAIN PARTITIONS SELECT * FROM trb1 WHERE id < 5\G
***** 1. row *****
      id: 1
    select_type: SIMPLE
        table: trb1
    partitions: p0,p1
         type: ALL
possible_keys: NULL
         key: NULL
      key_len: NULL
         ref: NULL
        rows: 10
      Extra: Using where
```

EXPLAIN PARTITIONS provides information about keys used and possible keys, just as with the standard **EXPLAIN SELECT** statement:

```
mysql> ALTER TABLE trb1 ADD PRIMARY KEY (id);
Query OK, 10 rows affected (0.03 sec)
Records: 10 Duplicates: 0 Warnings: 0

mysql> EXPLAIN PARTITIONS SELECT * FROM trb1 WHERE id < 5\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: trb1
   partitions: p0,p1
         type: range
possible_keys: PRIMARY
          key: PRIMARY
      key_len: 4
         ref: NULL
        rows: 7
      Extra: Using where
```

You should take note of the following restrictions and limitations on **EXPLAIN PARTITIONS**:

- You cannot use the **PARTITIONS** and **EXTENDED** keywords together in the same **EXPLAIN . . . SELECT** statement. Attempting to do so produces a syntax error.
- If **EXPLAIN PARTITIONS** is used to examine a query against a non-partitioned table, no error is produced, but the value of the **partitions** column is always **NULL**.

See also [Section 6.2.1, “Optimizing Queries with EXPLAIN”](#).

17.4. Partition Pruning

This section discusses *partition pruning*, an optimisation which was implemented for partitioned tables in MySQL 5.1.6. The core concept behind partition pruning is relatively simple, and can be described as “Do not scan partitions where there can be no matching values”. For example, suppose you have a partitioned table **t1** defined by this statement:

```
CREATE TABLE t1 (
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  region_code TINYINT UNSIGNED NOT NULL,
  dob DATE NOT NULL
)
PARTITION BY RANGE( region_code ) (
  PARTITION p0 VALUES LESS THAN (64),
  PARTITION p1 VALUES LESS THAN (128),
  PARTITION p2 VALUES LESS THAN (192),
  PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

Consider the case where you wish to obtain results from a query such as this one:

```
SELECT fname, lname, postcode, dob
FROM t1
WHERE region_code > 125 AND region_code < 130;
```

It is easy to see that none of the rows which ought to be returned will be in either of the partitions **p0** or **p3**; that is, we need to search only in partitions **p1** and **p2** to find matching rows. By doing so, it is possible to expend much more time and effort in finding matching rows than it is to scan all partitions in the table. This “cutting away” of unneeded partitions is known as *pruning*. When the optimizer can make use of partition pruning in performing a query, execution of the query can be an order of magnitude faster than the same query against a non-partitioned table containing the same column definitions and data.

The query optimizer can perform pruning whenever a **WHERE** condition can be reduced to either one of the following:

- *partition_column = constant*
- *partition_column IN (constant1, constant2, ..., constantN)*

In the first case, the optimizer simply evaluates the partitioning expression for the value given, determines which partition contains that value, and scans only this partition. In many cases, the equals sign can be replaced with another arithmetic comparison, including `<`, `>`, `<=`, `>=`, and `<>`. Some queries using `BETWEEN` in the `WHERE` clause can also take advantage of partition pruning. See the examples later in this section.

In the second case, the optimizer evaluates the partitioning expression for each value in the list, creates a list of matching partitions, and then scans only the partitions in this partition list.

Pruning can also be applied to short ranges, which the optimizer can convert into equivalent lists of values. For instance, in the previous example, the `WHERE` clause can be converted to `WHERE region_code IN (125, 126, 127, 128, 129, 130)`. Then the optimizer can determine that the first three values in the list are found in partition `p1`, the remaining three values in partition `p2`, and that the other partitions contain no relevant values and so do not need to be searched for matching rows.

This type of optimization can be applied whenever the partitioning expression consists of an equality or a range which can be reduced to a set of equalities, or when the partitioning expression represents an increasing or decreasing relationship. Pruning can also be applied for tables partitioned on a `DATE` or `DATETIME` column when the partitioning expression uses the `YEAR()` or `TO_DAYS()` function.

Note

We plan to add pruning support in a future MySQL release for additional functions that act on a `DATE` or `DATETIME` value, return an integer, and are increasing or decreasing.

For example, suppose that table `t2`, defined as shown here, is partitioned on a `DATE` column:

```
CREATE TABLE t2 (
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  region_code TINYINT UNSIGNED NOT NULL,
  dob DATE NOT NULL
)
PARTITION BY RANGE( YEAR(dob) ) (
  PARTITION d0 VALUES LESS THAN (1970),
  PARTITION d1 VALUES LESS THAN (1975),
  PARTITION d2 VALUES LESS THAN (1980),
  PARTITION d3 VALUES LESS THAN (1985),
  PARTITION d4 VALUES LESS THAN (1990),
  PARTITION d5 VALUES LESS THAN (2000),
  PARTITION d6 VALUES LESS THAN (2005),
  PARTITION d7 VALUES LESS THAN MAXVALUE
);
```

The following queries on `t2` can make use of partition pruning:

```
SELECT * FROM t2 WHERE dob = '1982-06-23';
SELECT * FROM t2 WHERE dob BETWEEN '1991-02-15' AND '1997-04-25';
SELECT * FROM t2 WHERE YEAR(dob)
  IN (1979, 1980, 1983, 1985, 1986, 1988);
SELECT * FROM t2 WHERE dob >= '1984-06-21' AND dob <= '1999-06-21'
```

In the case of the last query, the optimizer can also act as follows:

1. Find the partition containing the low end of the range.
`YEAR( '1984-06-21' )` yields the value `1984`, which is found in partition `d3`.
2. Find the partition containing the high end of the range.
`YEAR( '1999-06-21' )` evaluates to `1999`, which is found in partition `d5`.
3. Scan only these two partitions and any partitions that may lie between them.

In this case, this means that only partitions `d3`, `d4`, and `d5` are scanned. The remaining partitions may be safely ignored (and are ignored).

So far, we have looked only at examples using `RANGE` partitioning, but pruning can be applied with other partitioning types as well.

Consider a table that is partitioned by `LIST`, where the partitioning expression is increasing or decreasing, such as the table `t3` shown

here. (In this example, we assume for the sake of brevity that the `region_code` column is limited to values between 1 and 10 inclusive.)

```
CREATE TABLE t3 (
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  region_code TINYINT UNSIGNED NOT NULL,
  dob DATE NOT NULL
)
PARTITION BY LIST(region_code) (
  PARTITION r0 VALUES IN (1, 3),
  PARTITION r1 VALUES IN (2, 5, 8),
  PARTITION r2 VALUES IN (4, 9),
  PARTITION r3 VALUES IN (6, 7, 10)
);
```

For a query such as `SELECT * FROM t3 WHERE region_code BETWEEN 1 AND 3`, the optimizer determines in which partitions the values 1, 2, and 3 are found (`r0` and `r1`) and skips the remaining ones (`r2` and `r3`).

For tables that are partitioned by `HASH` or `KEY`, partition pruning is also possible in cases in which the `WHERE` clause uses a simple `=` relation against a column used in the partitioning expression. Consider a table created like this:

```
CREATE TABLE t4 (
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  region_code TINYINT UNSIGNED NOT NULL,
  dob DATE NOT NULL
)
PARTITION BY KEY(region_code)
PARTITIONS 8;
```

Any query such as this one can be pruned:

```
SELECT * FROM t4 WHERE region_code = 7;
```

Pruning can also be employed for short ranges, because the optimizer can turn such conditions into `IN` relations. For example, using the same table `t4` as defined previously, queries such as these can be pruned:

```
SELECT * FROM t4 WHERE region_code > 2 AND region_code < 6;
SELECT * FROM t4 WHERE region_code BETWEEN 3 AND 5;
```

In both these cases, the `WHERE` clause is transformed by the optimizer into `WHERE region_code IN (3, 4, 5)`.

Important

This optimization is used only if the range size is smaller than the number of partitions. Consider this query:

```
SELECT * FROM t4 WHERE region_code BETWEEN 4 AND 8;
```

The range in the `WHERE` clause covers 5 values (4, 5, 6, 7, 8), but `t4` has only 4 partitions. This means that the previous query cannot be pruned.

Pruning can be used only on integer columns of tables partitioned by `HASH` or `KEY`. For example, this query on table `t4` cannot use pruning because `dob` is a `DATE` column:

```
SELECT * FROM t4 WHERE dob >= '2001-04-14' AND dob <= '2005-10-15';
```

However, if the table stores year values in an `INT` column, then a query having `WHERE year_col >= 2001 AND year_col <= 2005` can be pruned.

17.5. Restrictions and Limitations on Partitioning

This section discusses current restrictions and limitations on MySQL partitioning support, as listed here:

- **Prohibited constructs.** Beginning with MySQL 5.1.12, the following constructs are not permitted in partitioning expressions:
 - Stored functions, stored procedures, UDFs, or plugins.

- Declared variables or user variables.

For SQL functions which are not permitted in partitioning expressions, see [Section 17.5.3.2, “Functions Not Permitted in Partitioning Expressions”](#).

- **Arithmetic and logical operators.** Use of the arithmetic operators `+`, `-`, `*`, and `/` is permitted in partitioning expressions. However, the result must be an integer value or `NULL` (except in the case of `[LINEAR] KEY` partitioning, as discussed elsewhere in this chapter — see [Section 17.2, “Partition Types”](#), for more information).

Beginning with MySQL 5.1.12, the bit operators `|`, `&`, `^`, `<<`, `>>`, and `~` are not permitted in partitioning expressions.

- **Server SQL mode.** Tables employing user-defined partitioning do not preserve the SQL mode in effect at the time that they were created. As discussed in [Section 5.2.6, “SQL Modes”](#), the results of many MySQL functions and operators may change according to the server SQL mode. Therefore, a change in the SQL mode at any time after the creation of partitioned tables may lead to major changes in the behavior of such tables, and could easily lead to corruption or loss of data. For these reasons, *it is strongly recommended that you never change the server SQL mode after creating partitioned tables*.

- **Maximum number of partitions.** The maximum number of partitions possible for a given table is 1024. This includes subpartitions.

If, when creating tables with a very large number of partitions (but which is less than the maximum stated previously), you encounter an error message such as `GOT ERROR 24 FROM STORAGE ENGINE`, this means that you may need to increase the value of the `open_files_limit` system variable. See [Section B.1.2.17, “‘FILE’ NOT FOUND and Similar Errors”](#).

- **Foreign keys.** Partitioned tables do not support foreign keys. This includes partitioned tables employing the `InnoDB` storage engine.
- **FULLTEXT indexes.** Partitioned tables do not support `FULLTEXT` indexes. This includes partitioned tables employing the `MyISAM` storage engine.
- **GEOMETRY columns.** Partitioned tables do not support `GEOMETRY` columns.
- **Temporary tables.** As of MySQL 5.1.8, temporary tables cannot be partitioned. ([Bug#17497](#))
- **Log tables.** Beginning with MySQL 5.1.20, it is no longer possible to partition the log tables; beginning with that version, an `ALTER TABLE ... PARTITION BY ...` statement on such a table fails with an error. ([Bug#27816](#))
- **Data type of partitioning key.** A partitioning key must be either an integer column or an expression that resolves to an integer. The column or expression value may also be `NULL`. (See [Section 17.2.6, “How MySQL Partitioning Handles NULL Values”](#).)

The lone exception to this restriction occurs when partitioning by `[LINEAR] KEY` — where it is possible to use columns of other types as partitioning keys — because MySQL’s internal key-hashing functions produce the correct data type from these types. For example, the following `CREATE TABLE` statement is valid:

```
CREATE TABLE tkc (c1 CHAR)
PARTITION BY KEY(c1)
PARTITIONS 4;
```

This exception does *not* apply to `BLOB` or `TEXT` column types.

- **Subqueries.** A partitioning key may not be a subquery, even if that subquery resolves to an integer value or `NULL`.
- **Subpartitions.** Subpartitions are limited to `HASH` or `KEY` partitioning. `HASH` and `KEY` partitions cannot be subpartitioned.
- **LOAD INDEX INTO CACHE.** The `LOAD INDEX INTO CACHE` statement is not supported for partitioned tables. Attempting to load an index from a partitioned table into a key cache results in the error `THE STORAGE ENGINE FOR THE TABLE DOESN'T SUPPORT PRELOAD_KEYS`.

17.5.1. Partitioning Keys, Primary Keys, and Unique Keys

This section discusses the relationship of partitioning keys with primary keys and unique keys. The rule governing this relationship can be expressed as follows: All columns used in the partitioning expression for a partitioned table must be part of every unique key that the table may have.

In other words, *every unique key on the table must use every column in the table's partitioning expression*. (This also includes the table's primary key, since it is by definition a unique key. This particular case is discussed later in this section.) For example, each of the following table creation statements is invalid:

```
CREATE TABLE t1 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  UNIQUE KEY (col1, col2)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t2 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  UNIQUE KEY (col1),
  UNIQUE KEY (col3)
)
PARTITION BY HASH(col1 + col3)
PARTITIONS 4;
```

In each case, the proposed table would have at least one unique key that does not include all columns used in the partitioning expression.

Each of the following statements is valid, and represents one way in which the corresponding invalid table creation statement could be made to work:

```
CREATE TABLE t1 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  UNIQUE KEY (col1, col2, col3)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t2 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  UNIQUE KEY (col1, col3)
)
PARTITION BY HASH(col1 + col3)
PARTITIONS 4;
```

This example shows the error produced in such cases:

```
mysql> CREATE TABLE t3 (
->   col1 INT NOT NULL,
->   col2 DATE NOT NULL,
->   col3 INT NOT NULL,
->   col4 INT NOT NULL,
->   UNIQUE KEY (col1, col2),
->   UNIQUE KEY (col3)
-> )
-> PARTITION BY HASH(col1 + col3)
-> PARTITIONS 4;
ERROR 1491 (HY000): A PRIMARY KEY MUST INCLUDE ALL COLUMNS IN THE TABLE'S PARTITIONING FUNCTION
```

The **CREATE** statement fails because both **col1** and **col3** are included in the proposed partitioning key, but neither of these columns is part of both of unique keys on the table. This shows one possible fix for the invalid table definition;

```
mysql> CREATE TABLE t3 (
->   col1 INT NOT NULL,
->   col2 DATE NOT NULL,
->   col3 INT NOT NULL,
->   col4 INT NOT NULL,
->   UNIQUE KEY (col1, col2, col3),
->   UNIQUE KEY (col3)
-> )
-> PARTITION BY HASH(col3)
-> PARTITIONS 4;
Query OK, 0 rows affected (0.05 sec)
```

In this case, the proposed partitioning key **col3** is part of both unique keys, and the table creation statement succeeds.

Since every primary key is by definition a unique key, this restriction also includes the table's primary key, if it has one. For example, the next two statements are invalid:

```
CREATE TABLE t4 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  PRIMARY KEY(col1, col2)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t5 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  PRIMARY KEY(col1, col3),
  UNIQUE KEY(col2)
)
PARTITION BY HASH( YEAR(col2) )
PARTITIONS 4;
```

In both cases, the primary key does not include all columns referenced in the partitioning expression. However, both of the next two statements are valid:

```
CREATE TABLE t6 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  PRIMARY KEY(col1, col2)
)
PARTITION BY HASH(col1 + YEAR(col2))
PARTITIONS 4;

CREATE TABLE t7 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  PRIMARY KEY(col1, col2, col4),
  UNIQUE KEY(col2, col1)
)
PARTITION BY HASH(col1 + YEAR(col2))
PARTITIONS 4;
```

If a table has no unique keys — this includes having no primary key — then this restriction does not apply, and you may use any column or columns in the partitioning expression as long as the column type is compatible with the partitioning type.

For the same reason, you cannot later add a unique key to a partitioned table unless the key includes all columns used by the table's partitioning expression. Consider given the partitioned table defined as shown here:

```
CREATE TABLE t_no_pk (c1 INT, c2 INT)
PARTITION BY RANGE(c1) (
  PARTITION p0 VALUES LESS THAN (10),
  PARTITION p1 VALUES LESS THAN (20),
  PARTITION p2 VALUES LESS THAN (30),
  PARTITION p3 VALUES LESS THAN (40)
);
```

It is possible to add a primary key to `t_no_pk` using either of these `ALTER TABLE` statements:

```
# possible PK
ALTER TABLE t_no_pk ADD PRIMARY KEY(c1);

# also a possible PK
ALTER TABLE t_no_pk ADD PRIMARY KEY(c1, c2);
```

However, the next statement fails, because `c1` is part of the partitioning key, but is not part of the proposed primary key:

```
# fails with ERROR 1482
ALTER TABLE t_no_pk ADD PRIMARY KEY(c2);
```

Since `t_no_pk` has only `c1` in its partitioning expression, attempting to adding a unique key on `c2` alone fails. However, you can add a unique key that uses both `c1` and `c2`.

These rules also apply to existing non-partitioned tables that you wish to partition using `ALTER TABLE ... PARTITION BY`. Consider a table `np_pk` defined as shown here:

```
CREATE TABLE np_pk (
  id INT NOT NULL AUTO_INCREMENT,
  name VARCHAR(50),
  added DATE,
  PRIMARY KEY (id)
);
```

The following `ALTER TABLE` statements fails with an error, because the `added` column is not part of any unique key in the table:

```
ALTER TABLE np_pk
PARTITION BY HASH( TO_DAYS(added) )
PARTITIONS 4;
```

This statement, however, would be valid:

```
ALTER TABLE np_pk
PARTITION BY HASH(id)
PARTITIONS 4;
```

In the case of `np_pk`, the only column that may be used as part of a partitioning expression is `id`; if you wish to partition this table using any other column or columns in the partitioning expression, you must first modify the table, either by adding the desired column or columns to the primary key, or by dropping the primary key altogether.

We are working to remove this limitation in a future MySQL release series.

17.5.2. Partitioning Limitations Relating to Storage Engines

The following limitations apply to the use of storage engines with user-defined partitioning of tables.

MERGE storage engine. Tables using the `MERGE` storage engine cannot be partitioned.

FEDERATED storage engine. Partitioning of `FEDERATED` tables is not supported. Beginning with MySQL 5.1.15, it is not possible to create partitioned `FEDERATED` tables at all. We are working to remove this limitation in a future MySQL release.

CSV storage engine. Partitioned tables using the `CSV` storage engine are not supported. Starting with MySQL 5.1.12, it is not possible to create partitioned `CSV` tables at all.

BLACKHOLE storage engine. Prior to MySQL 5.1.6, tables using the `BLACKHOLE` storage engine also could not be partitioned.

NDB storage engine (MySQL Cluster). Partitioning by `KEY` (or `LINEAR KEY`) is the only type of partitioning supported for the `NDB` storage engine. Beginning with MySQL 5.1.12, it is not possible to create a Cluster table using any partitioning type other than `[LINEAR] KEY`, and attempting to do so gives rise to an error.

Upgrading partitioned tables. When performing an upgrade, tables which are partitioned by `KEY` and that use any storage engine other than `NDBCLUSTER` and must be dumped and reloaded.

Same storage engine for all partitions. All of a table's partitions and subpartitions (if there are any of the latter) must use the same storage engine. We are working to remove this limitation in a future MySQL release.

17.5.3. Partitioning Limitations Relating to Functions

This section discusses limitations in MySQL Partitioning relating specifically to functions used in partitioning expressions, including both those function which are specifically supported for use in partitioning expressions, and those which are specifically prohibited.

17.5.3.1. Functions Supported in Partitioning Expressions

Beginning with MySQL 5.1.12, only the following MySQL functions are specifically supported in partitioning expressions:

- `ABS()`
- `CEILING()`

- `DAY()`
- `DAYOFMONTH()`
- `DAYOFWEEK()`
- `DAYOFYEAR()`
- `DATEDIFF()`
- `EXTRACT()`
- `FLOOR()`
- `HOUR()`
- `MICROSECOND()`
- `MINUTE()`
- `MOD()`
- `MONTH()`
- `QUARTER()`
- `SECOND()`
- `TIME_TO_SEC()`
- `TO_DAYS()`
- `WEEKDAY()`
- `YEAR()`
- `YEARWEEK()`

17.5.3.2. Functions Not Permitted in Partitioning Expressions

Beginning with MySQL 5.1.12, the following MySQL functions are specifically not allowed in partitioning expressions:

- `ASCII()`
- `BIT_COUNT()`
- `BIT_LENGTH()`
- `CASE()`
- `CAST()`
- `CHAR_LENGTH()`
- `CHARACTER_LENGTH()`
- `CONVERT()`
- `CRC32()`
- `FIND_IN_SET()`
- `GREATEST()`
- `IFNULL()`

- `INET_ATON()`
- `INSTR()`
- `ISNULL()`
- `LEAST()`
- `LENGTH()`
- `LOCATE()`
- `NULLIF()`
- `OCTET_LENGTH()`
- `ORD()`
- `PERIOD_ADD()`
- `PERIOD_DIFF()`
- `POSITION()`
- `ROUND()`
- `SIGN()`
- `STRCMP()`
- `TIMESTAMPDIFF()`
- `UNIX_TIMESTAMP()`
- `WEEK()`
- `WEEKOFYEAR()`

Chapter 18. Spatial Extensions

MySQL supports spatial extensions to allow the generation, storage, and analysis of geographic features. These features are available for [MyISAM](#), [InnoDB](#), [NDB](#), and [ARCHIVE](#) tables.

For spatial columns, [MyISAM](#) supports both [SPATIAL](#) and non-[SPATIAL](#) indexes. Other storage engines support non-[SPATIAL](#) indexes, as described in [Section 12.1.7, “CREATE INDEX Syntax”](#).

This chapter covers the following topics:

- The basis of these spatial extensions in the OpenGIS geometry model
- Data formats for representing spatial data
- How to use spatial data in MySQL
- Use of indexing for spatial data
- MySQL differences from the OpenGIS specification

Additional resources

- The Open Geospatial Consortium publishes the *OpenGIS® Simple Features Specifications For SQL*, a document that proposes several conceptual ways for extending an SQL RDBMS to support spatial data. This specification is available from the OGC Web site at <http://www.opengis.org/docs/99-049.pdf>.
- If you have questions or concerns about the use of the spatial extensions to MySQL, you can discuss them in the GIS forum: <http://forums.mysql.com/list.php?23>.

18.1. Introduction to MySQL Spatial Support

MySQL implements spatial extensions following the specification of the Open Geospatial Consortium (OGC). This is an international consortium of more than 250 companies, agencies, and universities participating in the development of publicly available conceptual solutions that can be useful with all kinds of applications that manage spatial data. The OGC maintains a Web site at <http://www.opengis.org/>.

In 1997, the Open Geospatial Consortium published the *OpenGIS® Simple Features Specifications For SQL*, a document that proposes several conceptual ways for extending an SQL RDBMS to support spatial data. This specification is available from the OGC Web site at <http://www.opengis.org/docs/99-049.pdf>. It contains additional information relevant to this chapter.

MySQL implements a subset of the **SQL with Geometry Types** environment proposed by OGC. This term refers to an SQL environment that has been extended with a set of geometry types. A geometry-valued SQL column is implemented as a column that has a geometry type. The specification describes a set of SQL geometry types, as well as functions on those types to create and analyze geometry values.

A **geographic feature** is anything in the world that has a location. A feature can be:

- An entity. For example, a mountain, a pond, a city.
- A space. For example, town district, the tropics.
- A definable location. For example, a crossroad, as a particular place where two streets intersect.

Some documents use the term **geospatial feature** to refer to geographic features.

Geometry is another word that denotes a geographic feature. Originally the word **geometry** meant measurement of the earth. Another meaning comes from cartography, referring to the geometric features that cartographers use to map the world.

This chapter uses all of these terms synonymously: **geographic feature**, **geospatial feature**, **feature**, or **geometry**. Here, the term most

commonly used is **geometry**, defined as *a point or an aggregate of points representing anything in the world that has a location*.

18.2. The OpenGIS Geometry Model

The set of geometry types proposed by OGC's **SQL with Geometry Types** environment is based on the **OpenGIS Geometry Model**. In this model, each geometric object has the following general properties:

- It is associated with a Spatial Reference System, which describes the coordinate space in which the object is defined.
- It belongs to some geometry class.

18.2.1. The Geometry Class Hierarchy

The geometry classes define a hierarchy as follows:

- **Geometry** (non-instantiable)
 - **Point** (instantiable)
 - **Curve** (non-instantiable)
 - **LineString** (instantiable)
 - **Line**
 - **LinearRing**
 - **Surface** (non-instantiable)
 - **Polygon** (instantiable)
 - **GeometryCollection** (instantiable)
 - **MultiPoint** (instantiable)
 - **MultiCurve** (non-instantiable)
 - **MultiLineString** (instantiable)
 - **MultiSurface** (non-instantiable)
 - **MultiPolygon** (instantiable)

It is not possible to create objects in non-instantiable classes. It is possible to create objects in instantiable classes. All classes have properties, and instantiable classes may also have assertions (rules that define valid class instances).

Geometry is the base class. It is an abstract class. The instantiable subclasses of **Geometry** are restricted to zero-, one-, and two-dimensional geometric objects that exist in two-dimensional coordinate space. All instantiable geometry classes are defined so that valid instances of a geometry class are topologically closed (that is, all defined geometries include their boundary).

The base **Geometry** class has subclasses for **Point**, **Curve**, **Surface**, and **GeometryCollection**:

- **Point** represents zero-dimensional objects.
- **Curve** represents one-dimensional objects, and has subclass **LineString**, with sub-subclasses **Line** and **LinearRing**.
- **Surface** is designed for two-dimensional objects and has subclass **Polygon**.
- **GeometryCollection** has specialized zero-, one-, and two-dimensional collection classes named **MultiPoint**, **MultiLineString**, and **MultiPolygon** for modeling geometries corresponding to collections of **Points**, **LineStrings**, and **Polygons**, respectively. **MultiCurve** and **MultiSurface** are introduced as abstract superclasses that generalize the collection in-

terfaces to handle [Curves](#) and [Surfaces](#).

[Geometry](#), [Curve](#), [Surface](#), [MultiCurve](#), and [MultiSurface](#) are defined as non-instantiable classes. They define a common set of methods for their subclasses and are included for extensibility.

[Point](#), [LineString](#), [Polygon](#), [GeometryCollection](#), [MultiPoint](#), [MultiLineString](#), and [MultiPolygon](#) are instantiable classes.

18.2.2. Class [Geometry](#)

[Geometry](#) is the root class of the hierarchy. It is a non-instantiable class but has a number of properties that are common to all geometry values created from any of the [Geometry](#) subclasses. These properties are described in the following list. Particular subclasses have their own specific properties, described later.

Geometry Properties

A geometry value has the following properties:

- Its **type**. Each geometry belongs to one of the instantiable classes in the hierarchy.
- Its **SRID**, or Spatial Reference Identifier. This value identifies the geometry's associated Spatial Reference System that describes the coordinate space in which the geometry object is defined.

In MySQL, the SRID value is just an integer associated with the geometry value. All calculations are done assuming Euclidean (planar) geometry.

- Its **coordinates** in its Spatial Reference System, represented as double-precision (eight-byte) numbers. All non-empty geometries include at least one pair of (X,Y) coordinates. Empty geometries contain no coordinates.

Coordinates are related to the SRID. For example, in different coordinate systems, the distance between two objects may differ even when objects have the same coordinates, because the distance on the **planar** coordinate system and the distance on the **geocentric** system (coordinates on the Earth's surface) are different things.

- Its **interior**, **boundary**, and **exterior**.

Every geometry occupies some position in space. The exterior of a geometry is all space not occupied by the geometry. The interior is the space occupied by the geometry. The boundary is the interface between the geometry's interior and exterior.

- Its **MBR** (Minimum Bounding Rectangle), or Envelope. This is the bounding geometry, formed by the minimum and maximum (X,Y) coordinates:

```
((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))
```

- Whether the value is **simple** or **non-simple**. Geometry values of types ([LineString](#), [MultiPoint](#), [MultiLineString](#)) are either simple or non-simple. Each type determines its own assertions for being simple or non-simple.
- Whether the value is **closed** or **not closed**. Geometry values of types ([LineString](#), [MultiString](#)) are either closed or not closed. Each type determines its own assertions for being closed or not closed.
- Whether the value is **empty** or **non-empty**. A geometry is empty if it does not have any points. Exterior, interior, and boundary of an empty geometry are not defined (that is, they are represented by a [NULL](#) value). An empty geometry is defined to be always simple and has an area of 0.
- Its **dimension**. A geometry can have a dimension of -1, 0, 1, or 2:
 - -1 for an empty geometry.
 - 0 for a geometry with no length and no area.
 - 1 for a geometry with non-zero length and zero area.
 - 2 for a geometry with non-zero area.

Point objects have a dimension of zero. **LineString** objects have a dimension of 1. **Polygon** objects have a dimension of 2. The dimensions of **MultiPoint**, **MultiLineString**, and **MultiPolygon** objects are the same as the dimensions of the elements they consist of.

18.2.3. Class **Point**

A **Point** is a geometry that represents a single location in coordinate space.

Point Examples

- Imagine a large-scale map of the world with many cities. A **Point** object could represent each city.
- On a city map, a **Point** object could represent a bus stop.

Point Properties

- X-coordinate value.
- Y-coordinate value.
- **Point** is defined as a zero-dimensional geometry.
- The boundary of a **Point** is the empty set.

18.2.4. Class **Curve**

A **Curve** is a one-dimensional geometry, usually represented by a sequence of points. Particular subclasses of **Curve** define the type of interpolation between points. **Curve** is a non-instantiable class.

Curve Properties

- A **Curve** has the coordinates of its points.
- A **Curve** is defined as a one-dimensional geometry.
- A **Curve** is simple if it does not pass through the same point twice.
- A **Curve** is closed if its start point is equal to its endpoint.
- The boundary of a closed **Curve** is empty.
- The boundary of a non-closed **Curve** consists of its two endpoints.
- A **Curve** that is simple and closed is a **LinearRing**.

18.2.5. Class **LineString**

A **LineString** is a **Curve** with linear interpolation between points.

LineString Examples

- On a world map, **LineString** objects could represent rivers.
- In a city map, **LineString** objects could represent streets.

LineString Properties

- A **LineString** has coordinates of segments, defined by each consecutive pair of points.
- A **LineString** is a **Line** if it consists of exactly two points.
- A **LineString** is a **LinearRing** if it is both closed and simple.

18.2.6. Class Surface

A **Surface** is a two-dimensional geometry. It is a non-instantiable class. Its only instantiable subclass is **Polygon**.

Surface Properties

- A **Surface** is defined as a two-dimensional geometry.
- The OpenGIS specification defines a simple **Surface** as a geometry that consists of a single “patch” that is associated with a single exterior boundary and zero or more interior boundaries.
- The boundary of a simple **Surface** is the set of closed curves corresponding to its exterior and interior boundaries.

18.2.7. Class Polygon

A **Polygon** is a planar **Surface** representing a multisided geometry. It is defined by a single exterior boundary and zero or more interior boundaries, where each interior boundary defines a hole in the **Polygon**.

Polygon Examples

- On a region map, **Polygon** objects could represent forests, districts, and so on.

Polygon Assertions

- The boundary of a **Polygon** consists of a set of **LinearRing** objects (that is, **LineString** objects that are both simple and closed) that make up its exterior and interior boundaries.
- A **Polygon** has no rings that cross. The rings in the boundary of a **Polygon** may intersect at a **Point**, but only as a tangent.
- A **Polygon** has no lines, spikes, or punctures.
- A **Polygon** has an interior that is a connected point set.
- A **Polygon** may have holes. The exterior of a **Polygon** with holes is not connected. Each hole defines a connected component of the exterior.

The preceding assertions make a **Polygon** a simple geometry.

18.2.8. Class GeometryCollection

A **GeometryCollection** is a geometry that is a collection of one or more geometries of any class.

All the elements in a **GeometryCollection** must be in the same Spatial Reference System (that is, in the same coordinate system). There are no other constraints on the elements of a **GeometryCollection**, although the subclasses of **GeometryCollection** described in the following sections may restrict membership. Restrictions may be based on:

- Element type (for example, a **MultiPoint** may contain only **Point** elements)

- Dimension
- Constraints on the degree of spatial overlap between elements

18.2.9. Class **MultiPoint**

A **MultiPoint** is a geometry collection composed of **Point** elements. The points are not connected or ordered in any way.

MultiPoint Examples

- On a world map, a **MultiPoint** could represent a chain of small islands.
- On a city map, a **MultiPoint** could represent the outlets for a ticket office.

MultiPoint Properties

- A **MultiPoint** is a zero-dimensional geometry.
- A **MultiPoint** is simple if no two of its **Point** values are equal (have identical coordinate values).
- The boundary of a **MultiPoint** is the empty set.

18.2.10. Class **MultiCurve**

A **MultiCurve** is a geometry collection composed of **Curve** elements. **MultiCurve** is a non-instantiable class.

MultiCurve Properties

- A **MultiCurve** is a one-dimensional geometry.
- A **MultiCurve** is simple if and only if all of its elements are simple; the only intersections between any two elements occur at points that are on the boundaries of both elements.
- A **MultiCurve** boundary is obtained by applying the “mod 2 union rule” (also known as the “odd-even rule”): A point is in the boundary of a **MultiCurve** if it is in the boundaries of an odd number of **MultiCurve** elements.
- A **MultiCurve** is closed if all of its elements are closed.
- The boundary of a closed **MultiCurve** is always empty.

18.2.11. Class **MultiLineString**

A **MultiLineString** is a **MultiCurve** geometry collection composed of **LineString** elements.

MultiLineString Examples

- On a region map, a **MultiLineString** could represent a river system or a highway system.

18.2.12. Class **MultiSurface**

A **MultiSurface** is a geometry collection composed of surface elements. **MultiSurface** is a non-instantiable class. Its only instantiable subclass is **MultiPolygon**.

MultiSurface Assertions

- Two [MultiSurface](#) surfaces have no interiors that intersect.
- Two [MultiSurface](#) elements have boundaries that intersect at most at a finite number of points.

18.2.13. Class [MultiPolygon](#)

A [MultiPolygon](#) is a [MultiSurface](#) object composed of [Polygon](#) elements.

[MultiPolygon](#) Examples

- On a region map, a [MultiPolygon](#) could represent a system of lakes.

[MultiPolygon](#) Assertions

- A [MultiPolygon](#) has no two [Polygon](#) elements with interiors that intersect.
- A [MultiPolygon](#) has no two [Polygon](#) elements that cross (crossing is also forbidden by the previous assertion), or that touch at an infinite number of points.
- A [MultiPolygon](#) may not have cut lines, spikes, or punctures. A [MultiPolygon](#) is a regular, closed point set.
- A [MultiPolygon](#) that has more than one [Polygon](#) has an interior that is not connected. The number of connected components of the interior of a [MultiPolygon](#) is equal to the number of [Polygon](#) values in the [MultiPolygon](#).

[MultiPolygon](#) Properties

- A [MultiPolygon](#) is a two-dimensional geometry.
- A [MultiPolygon](#) boundary is a set of closed curves ([LineString](#) values) corresponding to the boundaries of its [Polygon](#) elements.
- Each [Curve](#) in the boundary of the [MultiPolygon](#) is in the boundary of exactly one [Polygon](#) element.
- Every [Curve](#) in the boundary of an [Polygon](#) element is in the boundary of the [MultiPolygon](#).

18.3. Supported Spatial Data Formats

This section describes the standard spatial data formats that are used to represent geometry objects in queries. They are:

- Well-Known Text (WKT) format
- Well-Known Binary (WKB) format

Internally, MySQL stores geometry values in a format that is not identical to either WKT or WKB format.

18.3.1. Well-Known Text (WKT) Format

The Well-Known Text (WKT) representation of Geometry is designed to exchange geometry data in ASCII form.

Examples of WKT representations of geometry objects:

- A [Point](#):

```
POINT(15 20)
```

Note that point coordinates are specified with no separating comma.

- A **LineString** with four points:

```
LINESTRING(0 0, 10 10, 20 25, 50 60)
```

Note that point coordinate pairs are separated by commas.

- A **Polygon** with one exterior ring and one interior ring:

```
POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))
```

- A **MultiPoint** with three **Point** values:

```
MULTIPOINT(0 0, 20 20, 60 60)
```

- A **MultiLineString** with two **LineString** values:

```
MULTILINESTRING((10 10, 20 20), (15 15, 30 15))
```

- A **MultiPolygon** with two **Polygon** values:

```
MULTIPOLYGON(((0 0,10 0,10 10,0 10,0 0)),((5 5,7 5,7 7,5 7, 5 5)))
```

- A **GeometryCollection** consisting of two **Point** values and one **LineString**:

```
GEOMETRYCOLLECTION(POINT(10 10), POINT(30 30), LINESTRING(15 15, 20 20))
```

A Backus-Naur grammar that specifies the formal production rules for writing WKT values can be found in the OpenGIS specification document referenced near the beginning of this chapter.

18.3.2. Well-Known Binary (WKB) Format

The Well-Known Binary (WKB) representation for geometric values is defined by the OpenGIS specification. It is also defined in the ISO *SQL/MM Part 3: Spatial* standard.

WKB is used to exchange geometry data as binary streams represented by **BLOB** values containing geometric WKB information.

WKB uses one-byte unsigned integers, four-byte unsigned integers, and eight-byte double-precision numbers (IEEE 754 format). A byte is eight bits.

For example, a WKB value that corresponds to **POINT(1 1)** consists of this sequence of 21 bytes (each represented here by two hex digits):

```
010100000000000000000000F03F000000000000F03F
```

The sequence may be broken down into these components:

```
Byte order : 01
WKB type   : 01000000
X          : 000000000000F03F
Y          : 000000000000F03F
```

Component representation is as follows:

- The byte order may be either 0 or 1 to indicate little-endian or big-endian storage. The little-endian and big-endian byte orders are also known as Network Data Representation (NDR) and External Data Representation (XDR), respectively.
- The WKB type is a code that indicates the geometry type. Values from 1 through 7 indicate **Point**, **LineString**, **Polygon**, **MultiPoint**, **MultiLineString**, **MultiPolygon**, and **GeometryCollection**.

- A `Point` value has X and Y coordinates, each represented as a double-precision value.

WKB values for more complex geometry values are represented by more complex data structures, as detailed in the OpenGIS specification.

18.4. Creating a Spatially Enabled MySQL Database

This section describes the data types you can use for representing spatial data in MySQL, and the functions available for creating and retrieving spatial values.

18.4.1. MySQL Spatial Data Types

MySQL has data types that correspond to OpenGIS classes. Some of these types hold single geometry values:

- `GEOMETRY`
- `POINT`
- `LINestring`
- `POLYGON`

`GEOMETRY` can store geometry values of any type. The other single-value types (`POINT`, `LINestring`, and `POLYGON`) restrict their values to a particular geometry type.

The other data types hold collections of values:

- `MULTIPOINT`
- `MULTILINestring`
- `MULTIPOLYGON`
- `GEOMETRYCOLLECTION`

`GEOMETRYCOLLECTION` can store a collection of objects of any type. The other collection types (`MULTIPOINT`, `MULTILINestring`, `MULTIPOLYGON`, and `GEOMETRYCOLLECTION`) restrict collection members to those having a particular geometry type.

18.4.2. Creating Spatial Values

This section describes how to create spatial values using Well-Known Text and Well-Known Binary functions that are defined in the OpenGIS standard, and using MySQL-specific functions.

18.4.2.1. Creating Geometry Values Using WKT Functions

MySQL provides a number of functions that take as input parameters a Well-Known Text representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry.

`GeomFromText()` accepts a WKT of any geometry type as its first argument. An implementation also provides type-specific construction functions for construction of geometry values of each geometry type.

- `GeomCollFromText(wkt[,srid]), GeometryCollectionFromText(wkt[,srid])`

Constructs a `GEOMETRYCOLLECTION` value using its WKT representation and SRID.

- `GeomFromText(wkt[,srid]), GeometryFromText(wkt[,srid])`

Constructs a geometry value of any type using its WKT representation and SRID.

- `LineFromText(wkt[,srid]), LineStringFromText(wkt[,srid])`
Constructs a `LINESTRING` value using its WKT representation and SRID.
- `MLineFromText(wkt[,srid]), MultiLineStringFromText(wkt[,srid])`
Constructs a `MULTILINESTRING` value using its WKT representation and SRID.
- `MPointFromText(wkt[,srid]), MultiPointFromText(wkt[,srid])`
Constructs a `MULTIPOINT` value using its WKT representation and SRID.
- `MPolyFromText(wkt[,srid]), MultiPolygonFromText(wkt[,srid])`
Constructs a `MULTIPOLYGON` value using its WKT representation and SRID.
- `PointFromText(wkt[,srid])`
Constructs a `POINT` value using its WKT representation and SRID.
- `PolyFromText(wkt[,srid]), PolygonFromText(wkt[,srid])`
Constructs a `POLYGON` value using its WKT representation and SRID.

The OpenGIS specification also defines the following optional functions, which MySQL does not implement. These functions construct `Polygon` or `MultiPolygon` values based on the WKT representation of a collection of rings or closed `LineString` values. These values may intersect.

- `BdMPolyFromText(wkt,srid)`
Constructs a `MultiPolygon` value from a `MultiLineString` value in WKT format containing an arbitrary collection of closed `LineString` values.
- `BdPolyFromText(wkt,srid)`
Constructs a `Polygon` value from a `MultiLineString` value in WKT format containing an arbitrary collection of closed `LineString` values.

18.4.2.2. Creating Geometry Values Using WKB Functions

MySQL provides a number of functions that take as input parameters a `BLOB` containing a Well-Known Binary representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry.

`GeomFromWKB()` accepts a WKB of any geometry type as its first argument. An implementation also provides type-specific construction functions for construction of geometry values of each geometry type.

- `GeomCollFromWKB(wkb[,srid]), GeometryCollectionFromWKB(wkb[,srid])`
Constructs a `GEOMETRYCOLLECTION` value using its WKB representation and SRID.
- `GeomFromWKB(wkb[,srid]), GeometryFromWKB(wkb[,srid])`
Constructs a geometry value of any type using its WKB representation and SRID.
- `LineFromWKB(wkb[,srid]), LineStringFromWKB(wkb[,srid])`
Constructs a `LINESTRING` value using its WKB representation and SRID.
- `MLineFromWKB(wkb[,srid]), MultiLineStringFromWKB(wkb[,srid])`
Constructs a `MULTILINESTRING` value using its WKB representation and SRID.
- `MPointFromWKB(wkb[,srid]), MultiPointFromWKB(wkb[,srid])`

Constructs a **MULTIPOINT** value using its WKB representation and SRID.

- **MPolyFromWKB(wkb[,srid]), MultiPolygonFromWKB(wkb[,srid])**

Constructs a **MULTIPOLYGON** value using its WKB representation and SRID.

- **PointFromWKB(wkb[,srid])**

Constructs a **POINT** value using its WKB representation and SRID.

- **PolyFromWKB(wkb[,srid]), PolygonFromWKB(wkb[,srid])**

Constructs a **POLYGON** value using its WKB representation and SRID.

The OpenGIS specification also describes optional functions for constructing **Polygon** or **MultiPolygon** values based on the WKB representation of a collection of rings or closed **LineString** values. These values may intersect. MySQL does not implement these functions:

- **BdMPolyFromWKB(wkb,srid)**

Constructs a **MultiPolygon** value from a **MultiLineString** value in WKB format containing an arbitrary collection of closed **LineString** values.

- **BdPolyFromWKB(wkb,srid)**

Constructs a **Polygon** value from a **MultiLineString** value in WKB format containing an arbitrary collection of closed **LineString** values.

18.4.2.3. Creating Geometry Values Using MySQL-Specific Functions

MySQL provides a set of useful non-standard functions for creating geometry WKB representations. The functions described in this section are MySQL extensions to the OpenGIS specification. The results of these functions are **BLOB** values containing WKB representations of geometry values with no SRID. The results of these functions can be substituted as the first argument for any function in the **GeomFromWKB()** function family.

- **GeometryCollection(g1,g2,...)**

Constructs a WKB **GeometryCollection**. If any argument is not a well-formed WKB representation of a geometry, the return value is **NULL**.

- **LineString(pt1,pt2,...)**

Constructs a WKB **LineString** value from a number of WKB **Point** arguments. If any argument is not a WKB **Point**, the return value is **NULL**. If the number of **Point** arguments is less than two, the return value is **NULL**.

- **MultiLineString(ls1,ls2,...)**

Constructs a WKB **MultiLineString** value using WKB **LineString** arguments. If any argument is not a WKB **LineString**, the return value is **NULL**.

- **MultiPoint(pt1,pt2,...)**

Constructs a WKB **MultiPoint** value using WKB **Point** arguments. If any argument is not a WKB **Point**, the return value is **NULL**.

- **MultiPolygon(poly1,poly2,...)**

Constructs a WKB **MultiPolygon** value from a set of WKB **Polygon** arguments. If any argument is not a WKB **Polygon**, the return value is **NULL**.

- **Point(x,y)**

Constructs a WKB [Point](#) using its coordinates.

- [Polygon\(*ls1*, *ls2*, ...\)](#)

Constructs a WKB [Polygon](#) value from a number of WKB [LineString](#) arguments. If any argument does not represent the WKB of a [LinearRing](#) (that is, not a closed and simple [LineString](#)) the return value is [NULL](#).

18.4.3. Creating Spatial Columns

MySQL provides a standard way of creating spatial columns for geometry types, for example, with [CREATE TABLE](#) or [ALTER TABLE](#). Currently, spatial columns are supported for [MyISAM](#), [InnoDB](#), [NDB](#), and [ARCHIVE](#) tables. See also the annotations about spatial indexes under [Section 18.6.1, “Creating Spatial Indexes”](#).

- Use the [CREATE TABLE](#) statement to create a table with a spatial column:

```
CREATE TABLE geom (g GEOMETRY);
```

- Use the [ALTER TABLE](#) statement to add or drop a spatial column to or from an existing table:

```
ALTER TABLE geom ADD pt POINT;
ALTER TABLE geom DROP pt;
```

18.4.4. Populating Spatial Columns

After you have created spatial columns, you can populate them with spatial data.

Values should be stored in internal geometry format, but you can convert them to that format from either Well-Known Text (WKT) or Well-Known Binary (WKB) format. The following examples demonstrate how to insert geometry values into a table by converting WKT values into internal geometry format:

- Perform the conversion directly in the [INSERT](#) statement:

```
INSERT INTO geom VALUES (GeomFromText('POINT(1 1)'));
SET @g = 'POINT(1 1)';
INSERT INTO geom VALUES (GeomFromText(@g));
```

- Perform the conversion prior to the [INSERT](#):

```
SET @g = GeomFromText('POINT(1 1)');
INSERT INTO geom VALUES (@g);
```

The following examples insert more complex geometries into the table:

```
SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (GeomFromText(@g));

SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))';
INSERT INTO geom VALUES (GeomFromText(@g));

SET @g =
'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0 0,1 1,2 2,3 3,4 4))';
INSERT INTO geom VALUES (GeomFromText(@g));
```

The preceding examples all use [GeomFromText\(\)](#) to create geometry values. You can also use type-specific functions:

```
SET @g = 'POINT(1 1)';
INSERT INTO geom VALUES (PointFromText(@g));

SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (LineStringFromText(@g));

SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))';
```

```
INSERT INTO geom VALUES (PolygonFromText(@g));  
SET @g =  
'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0 0,1 1,2 2,3 3,4 4))';  
INSERT INTO geom VALUES (GeomCollFromText(@g));
```

Note that if a client application program wants to use WKB representations of geometry values, it is responsible for sending correctly formed WKB in queries to the server. However, there are several ways of satisfying this requirement. For example:

- Inserting a `POINT(1 1)` value with hex literal syntax:

```
mysql> INSERT INTO geom VALUES  
-> (GeomFromWKB(0x010100000000000000000000F03F0000000000F03F));
```

- An ODBC application can send a WKB representation, binding it to a placeholder using an argument of `BLOB` type:

```
INSERT INTO geom VALUES (GeomFromWKB(?))
```

Other programming interfaces may support a similar placeholder mechanism.

- In a C program, you can escape a binary value using `mysql_real_escape_string()` and include the result in a query string that is sent to the server. See [Section 25.2.3.53](#), “`mysql_real_escape_string()`”.

18.4.5. Fetching Spatial Data

Geometry values stored in a table can be fetched in internal format. You can also convert them into WKT or WKB format.

- Fetching spatial data in internal format:

Fetching geometry values using internal format can be useful in table-to-table transfers:

```
CREATE TABLE geom2 (g GEOMETRY) SELECT g FROM geom;
```

- Fetching spatial data in WKT format:

The `AsText()` function converts a geometry from internal format into a WKT string.

```
SELECT AsText(g) FROM geom;
```

- Fetching spatial data in WKB format:

The `AsBinary()` function converts a geometry from internal format into a `BLOB` containing the WKB value.

```
SELECT AsBinary(g) FROM geom;
```

18.5. Analyzing Spatial Information

After populating spatial columns with values, you are ready to query and analyze them. MySQL provides a set of functions to perform various operations on spatial data. These functions can be grouped into four major categories according to the type of operation they perform:

- Functions that convert geometries between various formats
- Functions that provide access to qualitative or quantitative properties of a geometry
- Functions that describe relations between two geometries
- Functions that create new geometries from existing ones

Spatial analysis functions can be used in many contexts, such as:

- Any interactive SQL program, such as [mysql](#) or MySQL Query Browser
- Application programs written in any language that supports a MySQL client API

18.5.1. Geometry Format Conversion Functions

MySQL supports the following functions for converting geometry values between internal format and either WKT or WKB format:

- [AsBinary\(*g*\)](#)

Converts a value in internal geometry format to its WKB representation and returns the binary result.

```
SELECT AsBinary(g) FROM geom;
```

- [AsText\(*g*\)](#)

Converts a value in internal geometry format to its WKT representation and returns the string result.

```
mysql> SET @g = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(GeomFromText(@g));
+-----+
| AsText(GeomFromText(@g)) |
+-----+
| LINESTRING(1 1,2 2,3 3) |
+-----+
```

- [GeomFromText\(*wkt*\[,*srid*\]\)](#)

Converts a string value from its WKT representation into internal geometry format and returns the result. A number of type-specific functions are also supported, such as [PointFromText\(\)](#) and [LineFromText\(\)](#). See [Section 18.4.2.1, “Creating Geometry Values Using WKT Functions”](#).

- [GeomFromWKB\(*wkb*\[,*srid*\]\)](#)

Converts a binary value from its WKB representation into internal geometry format and returns the result. A number of type-specific functions are also supported, such as [PointFromWKB\(\)](#) and [LineFromWKB\(\)](#). See [Section 18.4.2.2, “Creating Geometry Values Using WKB Functions”](#).

18.5.2. Geometry Functions

Each function that belongs to this group takes a geometry value as its argument and returns some quantitative or qualitative property of the geometry. Some functions restrict their argument type. Such functions return [NULL](#) if the argument is of an incorrect geometry type. For example, [Area\(\)](#) returns [NULL](#) if the object type is neither [Polygon](#) nor [MultiPolygon](#).

18.5.2.1. General Geometry Functions

The functions listed in this section do not restrict their argument and accept a geometry value of any type.

- [Dimension\(*g*\)](#)

Returns the inherent dimension of the geometry value *g*. The result can be -1, 0, 1, or 2. The meaning of these values is given in [Section 18.2.2, “Class Geometry”](#).

```
mysql> SELECT Dimension(GeomFromText('LineString(1 1,2 2)'));
+-----+
| Dimension(GeomFromText('LineString(1 1,2 2)')) |
+-----+
| 1 |
+-----+
```

- **Envelope(*g*)**

Returns the Minimum Bounding Rectangle (MBR) for the geometry value *g*. The result is returned as a **Polygon** value.

The polygon is defined by the corner points of the bounding box:

```
POLYGON((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))
```

```
mysql> SELECT AsText(Envelope(GeomFromText('LineString(1 1,2 2)')));
+-----+
| AsText(Envelope(GeomFromText('LineString(1 1,2 2)')) |
+-----+
| POLYGON((1 1,2 1,2 2,1 2,1 1)) |
+-----+
```

- **GeometryType(*g*)**

Returns as a string the name of the geometry type of which the geometry instance *g* is a member. The name corresponds to one of the instantiable **Geometry** subclasses.

```
mysql> SELECT GeometryType(GeomFromText('POINT(1 1)'));
+-----+
| GeometryType(GeomFromText('POINT(1 1)')) |
+-----+
| POINT |
+-----+
```

- **SRID(*g*)**

Returns an integer indicating the Spatial Reference System ID for the geometry value *g*.

In MySQL, the SRID value is just an integer associated with the geometry value. All calculations are done assuming Euclidean (planar) geometry.

```
mysql> SELECT SRID(GeomFromText('LineString(1 1,2 2)',101));
+-----+
| SRID(GeomFromText('LineString(1 1,2 2)',101)) |
+-----+
| 101 |
+-----+
```

The OpenGIS specification also defines the following functions, which MySQL does not implement:

- **Boundary(*g*)**

Returns a geometry that is the closure of the combinatorial boundary of the geometry value *g*.

- **IsEmpty(*g*)**

Returns 1 if the geometry value *g* is the empty geometry, 0 if it is not empty, and -1 if the argument is **NULL**. If the geometry is empty, it represents the empty point set.

- **IsSimple(*g*)**

Currently, this function is a placeholder and should not be used. If implemented, its behavior will be as described in the next paragraph.

Returns 1 if the geometry value *g* has no anomalous geometric points, such as self-intersection or self-tangency. **IsSimple()** returns 0 if the argument is not simple, and -1 if it is **NULL**.

The description of each instantiable geometric class given earlier in the chapter includes the specific conditions that cause an instance of that class to be classified as not simple. (See [Section 18.2.1, “The Geometry Class Hierarchy”](#).)

18.5.2.2. Point Functions

A **Point** consists of X and Y coordinates, which may be obtained using the following functions:

- **X(*p*)**

Returns the X-coordinate value for the point *p* as a double-precision number.

```
mysql> SET @pt = 'Point(56.7 53.34)';
mysql> SELECT X(GeomFromText(@pt));
+-----+
| X(GeomFromText(@pt)) |
+-----+
|          56.7         |
+-----+
```

- **Y(*p*)**

Returns the Y-coordinate value for the point *p* as a double-precision number.

```
mysql> SET @pt = 'Point(56.7 53.34)';
mysql> SELECT Y(GeomFromText(@pt));
+-----+
| Y(GeomFromText(@pt)) |
+-----+
|          53.34        |
+-----+
```

18.5.2.3. LineString Functions

A **LineString** consists of **Point** values. You can extract particular points of a **LineString**, count the number of points that it contains, or obtain its length.

- **EndPoint(*ls*)**

Returns the **Point** that is the endpoint of the **LineString** value *ls*.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(EndPoint(GeomFromText(@ls)));
+-----+
| AsText(EndPoint(GeomFromText(@ls))) |
+-----+
| POINT(3 3)                          |
+-----+
```

- **GLength(*ls*)**

Returns as a double-precision number the length of the **LineString** value *ls* in its associated spatial reference.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT GLength(GeomFromText(@ls));
+-----+
| GLength(GeomFromText(@ls)) |
+-----+
|          2.8284271247462     |
+-----+
```

GLength() is a non-standard name. It corresponds to the OpenGIS **Length()** function.

- **NumPoints(*ls*)**

Returns the number of **Point** objects in the **LineString** value *ls*.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT NumPoints(GeomFromText(@ls));
+-----+
| NumPoints(GeomFromText(@ls)) |
+-----+
|          3                    |
+-----+
```

- `PointN(ls,N)`

Returns the *N*-th `Point` in the `LineString` value *ls*. Points are numbered beginning with 1.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(PointN(GeomFromText(@ls),2));
+-----+
| AsText(PointN(GeomFromText(@ls),2)) |
+-----+
| POINT(2 2) |
+-----+
```

- `StartPoint(ls)`

Returns the `Point` that is the start point of the `LineString` value *ls*.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(StartPoint(GeomFromText(@ls)));
+-----+
| AsText(StartPoint(GeomFromText(@ls))) |
+-----+
| POINT(1 1) |
+-----+
```

The OpenGIS specification also defines the following function, which MySQL does not implement:

- `IsRing(ls)`

Returns 1 if the `LineString` value *ls* is closed (that is, its `StartPoint()` and `EndPoint()` values are the same) and is simple (does not pass through the same point more than once). Returns 0 if *ls* is not a ring, and -1 if it is `NULL`.

18.5.2.4. MultiLineString Functions

- `GLength(mls)`

Returns as a double-precision number the length of the `MultiLineString` value *mls*. The length of *mls* is equal to the sum of the lengths of its elements.

```
mysql> SET @mls = 'MultiLineString((1 1,2 2,3 3),(4 4,5 5))';
mysql> SELECT GLength(GeomFromText(@mls));
+-----+
| GLength(GeomFromText(@mls)) |
+-----+
| 4.2426406871193 |
+-----+
```

`GLength()` is a non-standard name. It corresponds to the OpenGIS `Length()` function.

- `IsClosed(mls)`

Returns 1 if the `MultiLineString` value *mls* is closed (that is, the `StartPoint()` and `EndPoint()` values are the same for each `LineString` in *mls*). Returns 0 if *mls* is not closed, and -1 if it is `NULL`.

```
mysql> SET @mls = 'MultiLineString((1 1,2 2,3 3),(4 4,5 5))';
mysql> SELECT IsClosed(GeomFromText(@mls));
+-----+
| IsClosed(GeomFromText(@mls)) |
+-----+
| 0 |
+-----+
```

18.5.2.5. Polygon Functions

- `Area(poly)`

Returns as a double-precision number the area of the **Polygon** value *poly*, as measured in its spatial reference system.

```
mysql> SET @poly = 'Polygon((0 0,0 3,3 0,0 0),(1 1,1 2,2 1,1 1));'
mysql> SELECT Area(GeomFromText(@poly));
+-----+
| Area(GeomFromText(@poly)) |
+-----+
| 4 |
+-----+
```

- **ExteriorRing(*poly*)**

Returns the exterior ring of the **Polygon** value *poly* as a **LineString**.

```
mysql> SET @poly =
-> 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1));'
mysql> SELECT AsText(ExteriorRing(GeomFromText(@poly)));
+-----+
| AsText(ExteriorRing(GeomFromText(@poly))) |
+-----+
| LINESTRING(0 0,0 3,3 3,3 0,0 0) |
+-----+
```

- **InteriorRingN(*poly*,*N*)**

Returns the *N*-th interior ring for the **Polygon** value *poly* as a **LineString**. Rings are numbered beginning with 1.

```
mysql> SET @poly =
-> 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1));'
mysql> SELECT AsText(InteriorRingN(GeomFromText(@poly),1));
+-----+
| AsText(InteriorRingN(GeomFromText(@poly),1)) |
+-----+
| LINESTRING(1 1,1 2,2 2,2 1,1 1) |
+-----+
```

- **NumInteriorRings(*poly*)**

Returns the number of interior rings in the **Polygon** value *poly*.

```
mysql> SET @poly =
-> 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1));'
mysql> SELECT NumInteriorRings(GeomFromText(@poly));
+-----+
| NumInteriorRings(GeomFromText(@poly)) |
+-----+
| 1 |
+-----+
```

18.5.2.6. MultiPolygon Functions

- **Area(*mpoly*)**

Returns as a double-precision number the area of the **MultiPolygon** value *mpoly*, as measured in its spatial reference system.

```
mysql> SET @mpoly =
-> 'MultiPolygon(((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1)))';
mysql> SELECT Area(GeomFromText(@mpoly));
+-----+
| Area(GeomFromText(@mpoly)) |
+-----+
| 8 |
+-----+
```

The OpenGIS specification also defines the following functions, which MySQL does not implement:

- **Centroid(*mpoly*)**

Returns the mathematical centroid for the **MultiPolygon** value *mpoly* as a **Point**. The result is not guaranteed to be on the **MultiPolygon**.

- **PointOnSurface(*mpoly*)**

Returns a **Point** value that is guaranteed to be on the **MultiPolygon** value *mpoly*.

18.5.2.7. GeometryCollection Functions

- **GeometryN(*gc*, *N*)**

Returns the *N*-th geometry in the **GeometryCollection** value *gc*. Geometries are numbered beginning with 1.

```
mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
mysql> SELECT AsText(GeometryN(GeomFromText(@gc),1));
+-----+
| AsText(GeometryN(GeomFromText(@gc),1)) |
+-----+
| POINT(1 1)                             |
+-----+
```

- **NumGeometries(*gc*)**

Returns the number of geometries in the **GeometryCollection** value *gc*.

```
mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
mysql> SELECT NumGeometries(GeomFromText(@gc));
+-----+
| NumGeometries(GeomFromText(@gc)) |
+-----+
| 2 |
+-----+
```

18.5.3. Functions That Create New Geometries from Existing Ones

18.5.3.1. Geometry Functions That Produce New Geometries

Section 18.5.2, “Geometry Functions”, discusses several functions that construct new geometries from existing ones. See that section for descriptions of these functions:

- **Envelope(*g*)**
- **StartPoint(*ls*)**
- **EndPoint(*ls*)**
- **PointN(*ls*, *N*)**
- **ExteriorRing(*poly*)**
- **InteriorRingN(*poly*, *N*)**
- **GeometryN(*gc*, *N*)**

18.5.3.2. Spatial Operators

OpenGIS proposes a number of other functions that can produce geometries. They are designed to implement spatial operators.

These functions are not implemented in MySQL. They may appear in future releases.

- **Buffer(*g*, *d*)**
Returns a geometry that represents all points whose distance from the geometry value *g* is less than or equal to a distance of *d*.
- **ConvexHull(*g*)**
Returns a geometry that represents the convex hull of the geometry value *g*.
- **Difference(*g1*, *g2*)**
Returns a geometry that represents the point set difference of the geometry value *g1* with *g2*.
- **Intersection(*g1*, *g2*)**
Returns a geometry that represents the point set intersection of the geometry values *g1* with *g2*.
- **SymDifference(*g1*, *g2*)**
Returns a geometry that represents the point set symmetric difference of the geometry value *g1* with *g2*.
- **Union(*g1*, *g2*)**
Returns a geometry that represents the point set union of the geometry values *g1* and *g2*.

18.5.4. Functions for Testing Spatial Relations Between Geometric Objects

The functions described in these sections take two geometries as input parameters and return a qualitative or quantitative relation between them.

18.5.5. Relations on Geometry Minimal Bounding Rectangles (MBRs)

MySQL provides several functions that test relations between minimal bounding rectangles of two geometries *g1* and *g2*. The return values 1 and 0 indicate true and false, respectively.

- **MBRContains(*g1*, *g2*)**

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangle of *g1* contains the Minimum Bounding Rectangle of *g2*. This tests the opposite relationship as **MBRWithin()**.

```
mysql> SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,0 0))');
mysql> SET @g2 = GeomFromText('Point(1 1)');
mysql> SELECT MBRContains(@g1,@g2), MBRContains(@g2,@g1);
+-----+-----+
| MBRContains(@g1,@g2) | MBRContains(@g2,@g1) |
+-----+-----+
| 1 | 0 |
+-----+-----+
```

- **MBRDisjoint(*g1*, *g2*)**

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries *g1* and *g2* are disjoint (do not intersect).

- **MBREqual(*g1*, *g2*)**

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries *g1* and *g2* are the same.

- **MBRIntersects(*g1*, *g2*)**

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries *g1* and *g2* intersect.

- **MBROverlaps(*g1*, *g2*)**

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries *g1* and *g2* overlap. The term *spatially overlaps* is used if two geometries intersect and their intersection results in a geometry of the same dimension but not equal to either

of the given geometries.

- **MBRTouches(*g1*,*g2*)**

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries *g1* and *g2* touch. Two geometries *spatially touch* if the interiors of the geometries do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

- **MBRWithin(*g1*,*g2*)**

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangle of *g1* is within the Minimum Bounding Rectangle of *g2*. This tests the opposite relationship as **MBRContains()**.

```
mysql> SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,0,0 0))');
mysql> SET @g2 = GeomFromText('Polygon((0 0,0 5,5 5,0,0 0))');
mysql> SELECT MBRWithin(@g1,@g2), MBRWithin(@g2,@g1);
+-----+-----+
| MBRWithin(@g1,@g2) | MBRWithin(@g2,@g1) |
+-----+-----+
| 1 | 0 |
+-----+-----+
```

18.5.6. Functions That Test Spatial Relationships Between Geometries

The OpenGIS specification defines the following functions. They test the relationship between two geometry values *g1* and *g2*.

The return values 1 and 0 indicate true and false, respectively.

Note

Currently, MySQL does not implement these functions according to the specification. Those that are implemented return the same result as the corresponding MBR-based functions. This includes functions in the following list other than **Distance()** and **Related()**.

These functions may be implemented in future releases with full support for spatial analysis, not just MBR-based support.

- **Contains(*g1*,*g2*)**

Returns 1 or 0 to indicate whether *g1* completely contains *g2*. This tests the opposite relationship as **Within()**.

- **Crosses(*g1*,*g2*)**

Returns 1 if *g1* spatially crosses *g2*. Returns **NULL** if *g1* is a **Polygon** or a **MultiPolygon**, or if *g2* is a **Point** or a **MultiPoint**. Otherwise, returns 0.

The term *spatially crosses* denotes a spatial relation between two given geometries that has the following properties:

- The two geometries intersect
- Their intersection results in a geometry that has a dimension that is one less than the maximum dimension of the two given geometries
- Their intersection is not equal to either of the two given geometries

- **Disjoint(*g1*,*g2*)**

Returns 1 or 0 to indicate whether *g1* is spatially disjoint from (does not intersect) *g2*.

- **Distance(*g1*,*g2*)**

Returns as a double-precision number the shortest distance between any two points in the two geometries.

- **Equals(*g1*,*g2*)**

Returns 1 or 0 to indicate whether *g1* is spatially equal to *g2*.

- `Intersects(g1,g2)`

Returns 1 or 0 to indicate whether *g1* spatially intersects *g2*.

- `Overlaps(g1,g2)`

Returns 1 or 0 to indicate whether *g1* spatially overlaps *g2*. The term *spatially overlaps* is used if two geometries intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

- `Related(g1,g2,pattern_matrix)`

Returns 1 or 0 to indicate whether the spatial relationship specified by *pattern_matrix* exists between *g1* and *g2*. Returns -1 if the arguments are `NULL`. The pattern matrix is a string. Its specification will be noted here if this function is implemented.

- `Touches(g1,g2)`

Returns 1 or 0 to indicate whether *g1* spatially touches *g2*. Two geometries *spatially touch* if the interiors of the geometries do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

- `Within(g1,g2)`

Returns 1 or 0 to indicate whether *g1* is spatially within *g2*. This tests the opposite relationship as `Contains()`.

18.6. Optimizing Spatial Analysis

Search operations in non-spatial databases can be optimized using `SPATIAL` indexes. This is true for spatial databases as well. With the help of a great variety of multi-dimensional indexing methods that have previously been designed, it is possible to optimize spatial searches. The most typical of these are:

- Point queries that search for all objects that contain a given point
- Region queries that search for all objects that overlap a given region

MySQL uses **R-Trees with quadratic splitting** for `SPATIAL` indexes on spatial columns. A `SPATIAL` index is built using the MBR of a geometry. For most geometries, the MBR is a minimum rectangle that surrounds the geometries. For a horizontal or a vertical line-string, the MBR is a rectangle degenerated into the linestring. For a point, the MBR is a rectangle degenerated into the point.

It is also possible to create normal indexes on spatial columns. In a non-`SPATIAL` index, you must declare a prefix for any spatial column except for `POINT` columns.

`MyISAM` supports both `SPATIAL` and non-`SPATIAL` indexes. Other storage engines support non-`SPATIAL` indexes, as described in [Section 12.1.7, “CREATE INDEX Syntax”](#).

18.6.1. Creating Spatial Indexes

MySQL can create spatial indexes using syntax similar to that for creating regular indexes, but extended with the `SPATIAL` keyword. Currently, columns in spatial indexes must be declared `NOT NULL`. The following examples demonstrate how to create spatial indexes:

- With `CREATE TABLE`:

```
CREATE TABLE geom (g GEOMETRY NOT NULL, SPATIAL INDEX(g));
```

- With `ALTER TABLE`:

```
ALTER TABLE geom ADD SPATIAL INDEX(g);
```

- With `CREATE INDEX`:

```
CREATE SPATIAL INDEX sp_index ON geom (g);
```

For **MyISAM** tables, **SPATIAL INDEX** creates an R-tree index. For storage engines that support non-spatial indexing of spatial columns, the engine creates a B-tree index. A B-tree index on spatial values will be useful for exact-value lookups, but not for range scans.

For more information on indexing spatial columns, see [Section 12.1.7, “CREATE INDEX Syntax”](#).

To drop spatial indexes, use **ALTER TABLE** or **DROP INDEX**:

- With **ALTER TABLE**:

```
ALTER TABLE geom DROP INDEX g;
```

- With **DROP INDEX**:

```
DROP INDEX sp_index ON geom;
```

Example: Suppose that a table **geom** contains more than 32,000 geometries, which are stored in the column **g** of type **GEOMETRY**. The table also has an **AUTO_INCREMENT** column **fid** for storing object ID values.

```
mysql> DESCRIBE geom;
+-----+-----+-----+-----+-----+-----+
| Field | Type   | Null | Key | Default | Extra           |
+-----+-----+-----+-----+-----+-----+
| fid   | int(11) |      | PRI | NULL    | auto_increment |
| g     | geometry |      |     |         |                |
+-----+-----+-----+-----+-----+-----+
2 rows in set (0.00 sec)

mysql> SELECT COUNT(*) FROM geom;
+-----+
| count(*) |
+-----+
|      32376 |
+-----+
1 row in set (0.00 sec)
```

To add a spatial index on the column **g**, use this statement:

```
mysql> ALTER TABLE geom ADD SPATIAL INDEX(g);
Query OK, 32376 rows affected (4.05 sec)
Records: 32376 Duplicates: 0 Warnings: 0
```

18.6.2. Using a Spatial Index

The optimizer investigates whether available spatial indexes can be involved in the search for queries that use a function such as **MBRContains()** or **MBRWithin()** in the **WHERE** clause. The following query finds all objects that are in the given rectangle:

```
mysql> SET @poly =
-> 'Polygon((30000 15000,
              31000 15000,
              31000 16000,
              30000 16000,
              30000 15000));'
mysql> SELECT fid, AsText(g) FROM geom WHERE
-> MBRContains(GeomFromText(@poly), g);
+-----+-----+
| fid | AsText(g) |
+-----+-----+
| 21 | LINESTRING(30350.4 15828.8,30350.6 15845,30333.8 15845,30 ... |
| 22 | LINESTRING(30350.6 15871.4,30350.6 15887.8,30334 15887.8, ... |
| 23 | LINESTRING(30350.6 15914.2,30350.6 15930.4,30334 15930.4, ... |
| 24 | LINESTRING(30290.2 15823,30290.2 15839.4,30273.4 15839.4, ... |
| 25 | LINESTRING(30291.4 15866.2,30291.6 15882.4,30274.8 15882. ... |
| 26 | LINESTRING(30291.6 15918.2,30291.6 15934.4,30275 15934.4, ... |
| 249 | LINESTRING(30337.8 15938.6,30337.8 15946.8,30320.4 15946. ... |
| 1 | LINESTRING(30250.4 15129.2,30248.8 15138.4,30238.2 15136. ... |
| 2 | LINESTRING(30220.2 15122.8,30217.2 15137.8,30207.6 15136. ... |
| 3 | LINESTRING(30179 15114.4,30176.6 15129.4,30167 15128,3016 ... |
| 4 | LINESTRING(30155.2 15121.4,30140.4 15118.6,30142 15109,30 ... |
| 5 | LINESTRING(30192.4 15085,30177.6 15082.2,30179.2 15072.4, ... |
| 6 | LINESTRING(30244 15087,30229 15086.2,30229.4 15076.4,3024 ... |
| 7 | LINESTRING(30200.6 15059.4,30185.6 15058.6,30186 15048.8, ... |
| 10 | LINESTRING(30179.6 15017.8,30181 15002.8,30190.8 15003.6, ... |
```

```

+----+-----+
| 11 | LINESTRING(30154.2 15000.4,30168.6 15004.8,30166 15014.2, ... |
| 13 | LINESTRING(30105 15065.8,30108.4 15050.8,30118 15053,3011 ... |
| 154 | LINESTRING(30276.2 15143.8,30261.4 15141,30263 15131.4,30 ... |
| 155 | LINESTRING(30269.8 15084,30269.4 15093.4,30258.6 15093,30 ... |
| 157 | LINESTRING(30128.2 15011,30113.2 15010.2,30113.6 15000.4, ... |
+----+-----+
20 rows in set (0.00 sec)

```

Use [EXPLAIN](#) to check the way this query is executed:

```

mysql> SET @poly =
-> 'Polygon((30000 15000,
           31000 15000,
           31000 16000,
           30000 16000,
           30000 15000));'
mysql> EXPLAIN SELECT fid,AsText(g) FROM geom WHERE
-> MBRContains(GeomFromText(@poly),g)\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: geom
        type: range
possible_keys: g
         key: g
        key_len: 32
         ref: NULL
        rows: 50
   Extra: Using where
1 row in set (0.00 sec)

```

Check what would happen without a spatial index:

```

mysql> SET @poly =
-> 'Polygon((30000 15000,
           31000 15000,
           31000 16000,
           30000 16000,
           30000 15000));'
mysql> EXPLAIN SELECT fid,AsText(g) FROM g IGNORE INDEX (g) WHERE
-> MBRContains(GeomFromText(@poly),g)\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: geom
        type: ALL
possible_keys: NULL
         key: NULL
        key_len: NULL
         ref: NULL
        rows: 32376
   Extra: Using where
1 row in set (0.00 sec)

```

Executing the [SELECT](#) statement without the spatial index yields the same result but causes the execution time to rise from 0.00 seconds to 0.46 seconds:

```

mysql> SET @poly =
-> 'Polygon((30000 15000,
           31000 15000,
           31000 16000,
           30000 16000,
           30000 15000));'
mysql> SELECT fid,AsText(g) FROM geom IGNORE INDEX (g) WHERE
-> MBRContains(GeomFromText(@poly),g);
+----+-----+
| fid | AsText(g) |
+----+-----+
| 1 | LINESTRING(30250.4 15129.2,30248.8 15138.4,30238.2 15136. ... |

```

In future releases, spatial indexes may also be used for optimizing other functions. See [Section 18.5.4, “Functions for Testing Spatial Relations Between Geometric Objects”](#).

18.7. MySQL Conformance and Compatibility

MySQL does not yet implement the following GIS features:

- Additional Metadata Views

OpenGIS specifications propose several additional metadata views. For example, a system view named `GEOMETRY_COLUMNS` contains a description of geometry columns, one row for each geometry column in the database.

- The OpenGIS function `Length()` on `LineString` and `MultiLineString` currently should be called in MySQL as `GLength()`

The problem is that there is an existing SQL function `Length()` that calculates the length of string values, and sometimes it is not possible to distinguish whether the function is called in a textual or spatial context. We need either to solve this somehow, or decide on another function name.

Chapter 19. Stored Procedures and Functions

Stored routines (procedures and functions) are supported in MySQL 5.1. A stored procedure is a set of SQL statements that can be stored in the server. Once this has been done, clients don't need to keep reissuing the individual statements but can refer to the stored procedure instead.

Answers to some questions that are commonly asked regarding stored routines in MySQL can be found in [Section A.4, “MySQL 5.1 FAQ — Stored Procedures”](#).

MySQL Enterprise

For expert advice on using stored procedures and functions subscribe to the MySQL Enterprise Monitor. For more information see <http://www.mysql.com/products/enterprise/advisors.html>.

Some situations where stored routines can be particularly useful:

- When multiple client applications are written in different languages or work on different platforms, but need to perform the same database operations.
- When security is paramount. Banks, for example, use stored procedures and functions for all common operations. This provides a consistent and secure environment, and routines can ensure that each operation is properly logged. In such a setup, applications and users would have no access to the database tables directly, but can only execute specific stored routines.

Stored routines can provide improved performance because less information needs to be sent between the server and the client. The tradeoff is that this does increase the load on the database server because more of the work is done on the server side and less is done on the client (application) side. Consider this if many client machines (such as Web servers) are serviced by only one or a few database servers.

Stored routines also allow you to have libraries of functions in the database server. This is a feature shared by modern application languages that allow such design internally (for example, by using classes). Using these client application language features is beneficial for the programmer even outside the scope of database use.

MySQL follows the SQL:2003 syntax for stored routines, which is also used by IBM's DB2.

The MySQL implementation of stored routines is still in progress. All syntax described in this chapter is supported and any limitations and extensions are documented where appropriate. Further discussion of restrictions on use of stored routines is given in [Section D.1, “Restrictions on Stored Routines and Triggers”](#).

Binary logging for stored routines takes place as described in [Section 19.4, “Binary Logging of Stored Routines and Triggers”](#).

Recursive stored procedures are disabled by default, but can be enabled on the server by setting the `max_sp_recursion_depth` server system variable to a nonzero value. See [Section 5.2.3, “System Variables”](#), for more information.

Stored functions cannot be recursive. See [Section D.1, “Restrictions on Stored Routines and Triggers”](#).

19.1. Stored Routines and the Grant Tables

Stored routines require the `proc` table in the `mysql` database. This table is created during the MySQL 5.1 installation procedure. If you are upgrading to MySQL 5.1 from an earlier version, be sure to update your grant tables to make sure that the `proc` table exists. See [Section 5.5.7, “mysql_upgrade — Check Tables for MySQL Upgrade”](#).

The server manipulates the `mysql.proc` table in response to statements that create, alter, or drop stored routines. It is not supported that the server will notice manual manipulation of this table.

The MySQL grant system takes stored routines into account as follows:

- The `CREATE ROUTINE` privilege is needed to create stored routines.
- The `ALTER ROUTINE` privilege is needed to alter or drop stored routines. This privilege is granted automatically to the creator of a routine if necessary, and dropped when the routine creator drops the routine.
- The `EXECUTE` privilege is required to execute stored routines. However, this privilege is granted automatically to the creator of a

routine if necessary (and dropped when the creator drops the routine). Also, the default `SQL SECURITY` characteristic for a routine is `DEFINER`, which enables users who have access to the database with which the routine is associated to execute the routine.

- If the `automatic_sp_privileges` system variable is 0, the `EXECUTE` and `ALTER ROUTINE` privileges are not automatically granted and dropped.

19.2. Stored Routine Syntax

A stored routine is either a procedure or a function. Stored routines are created with `CREATE PROCEDURE` and `CREATE FUNCTION` statements. A procedure is invoked using a `CALL` statement, and can only pass back values using output variables. A function can be called from inside a statement just like any other function (that is, by invoking the function's name), and can return a scalar value. Stored routines may call other stored routines.

A stored procedure or function is associated with a particular database. This has several implications:

- When the routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). `USE` statements within stored routines are disallowed.
- You can qualify routine names with the database name. This can be used to refer to a routine that is not in the current database. For example, to invoke a stored procedure `p` or function `f` that is associated with the `test` database, you can say `CALL test.p()` or `test.f()`.
- When a database is dropped, all stored routines associated with it are dropped as well.

MySQL supports the very useful extension that allows the use of regular `SELECT` statements (that is, without using cursors or local variables) inside a stored procedure. The result set of such a query is simply sent directly to the client. Multiple `SELECT` statements generate multiple result sets, so the client must use a MySQL client library that supports multiple result sets. This means the client must use a client library from a version of MySQL at least as recent as 4.1. The client should also specify the `CLIENT_MULTI_RESULTS` option when it connects. For C programs, this can be done with the `mysql_real_connect()` C API function. See [Section 25.2.3.52](#), “`mysql_real_connect()`”, and [Section 25.2.9](#), “C API Handling of Multiple Statement Execution”.

MySQL Enterprise

MySQL Enterprise subscribers will find numerous articles about stored routines in the MySQL Enterprise Knowledge Base. Access to this collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information see <http://www.mysql.com/products/enterprise/advisors.html>.

The following sections describe the syntax used to create, alter, drop, and invoke stored procedures and functions.

19.2.1. CREATE PROCEDURE and CREATE FUNCTION Syntax

```
CREATE
[DEFINER = { user | CURRENT_USER }]
PROCEDURE sp_name ([proc_parameter[,...]])
[characteristic ...] routine_body

CREATE
[DEFINER = { user | CURRENT_USER }]
FUNCTION sp_name ([func_parameter[,...]])
RETURNS type
[characteristic ...] routine_body

proc_parameter:
[ IN | OUT | INOUT ] param_name type

func_parameter:
param_name type

type:
Any valid MySQL data type

characteristic:
LANGUAGE SQL
| [NOT] DETERMINISTIC
| { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
| SQL SECURITY { DEFINER | INVOKER }
| COMMENT 'string'

routine_body:
Valid SQL procedure statement
```

These statements create stored routines. To use them, it is necessary to have the `CREATE ROUTINE` privilege. If binary logging is enabled, the `CREATE FUNCTION` statement might also require the `SUPER` privilege, as described in [Section 19.4, “Binary Logging of Stored Routines and Triggers”](#). MySQL automatically grants the `ALTER ROUTINE` and `EXECUTE` privileges to the routine creator.

By default, the routine is associated with the default database. To associate the routine explicitly with a given database, specify the name as `db_name.sp_name` when you create it.

If the routine name is the same as the name of a built-in SQL function, you must use a space between the name and the following parenthesis when defining the routine, or a syntax error occurs. This is also true when you invoke the routine later. For this reason, we suggest that it is better to avoid re-using the names of existing SQL functions for your own stored routines.

The `IGNORE_SPACE` SQL mode applies to built-in functions, not to stored routines. It is always allowable to have spaces after a routine name, regardless of whether `IGNORE_SPACE` is enabled.

The parameter list enclosed within parentheses must always be present. If there are no parameters, an empty parameter list of `()` should be used.

Each parameter can be declared to use any valid data type, except that the `COLLATE` attribute cannot be used.

Each parameter is an `IN` parameter by default. To specify otherwise for a parameter, use the keyword `OUT` or `INOUT` before the parameter name.

Note

Specifying a parameter as `IN`, `OUT`, or `INOUT` is valid only for a `PROCEDURE`. (`FUNCTION` parameters are always regarded as `IN` parameters.)

An `IN` parameter passes a value into a procedure. The procedure might modify the value, but the modification is not visible to the caller when the procedure returns. An `OUT` parameter passes a value from the procedure back to the caller. Its initial value is `NULL` within the procedure, and its value is visible to the caller when the procedure returns. An `INOUT` parameter is initialized by the caller, can be modified by the procedure, and any change made by the procedure is visible to the caller when the procedure returns.

For each `OUT` or `INOUT` parameter, pass a user-defined variable so that you can obtain its value when the procedure returns. (For an example, see [Section 19.2.4, “CALL Statement Syntax”](#).) If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an `IN` or `INOUT` parameter.

The `RETURNS` clause may be specified only for a `FUNCTION`, for which it is mandatory. It indicates the return type of the function, and the function body must contain a `RETURN value` statement. If the `RETURN` statement returns a value of a different type, the value is coerced to the proper type. For example, if a function specifies an `ENUM` or `SET` value in the `RETURNS` clause, but the `RETURN` statement returns an integer, the value returned from the function is the string for the corresponding `ENUM` member of set of `SET` members.

The `routine_body` consists of a valid SQL procedure statement. This can be a simple statement such as `SELECT` or `INSERT`, or it can be a compound statement written using `BEGIN` and `END`. Compound statement syntax is described in [Section 19.2.5, “BEGIN . . . END Compound Statement Syntax”](#). Compound statements can contain declarations, loops, and other control structure statements. The syntax for these statements is described later in this chapter. See, for example, [Section 19.2.6, “DECLARE Statement Syntax”](#), and [Section 19.2.10, “Flow Control Constructs”](#). Some statements are not allowed in stored routines; see [Section D.1, “Restrictions on Stored Routines and Triggers”](#).

MySQL stores the `sql_mode` system variable setting that is in effect at the time a routine is created, and always executes the routine with this setting in force, *regardless of the current server SQL mode*.

The `CREATE FUNCTION` statement was used in earlier versions of MySQL to support UDFs (user-defined functions). See [Section 28.3, “Adding New Functions to MySQL”](#). UDFs continue to be supported, even with the existence of stored functions. A UDF can be regarded as an external stored function. However, do note that stored functions share their namespace with UDFs. See [Section 8.2.4, “Function Name Parsing and Resolution”](#), for the rules describing how the server interprets references to different kinds of functions.

A procedure or function is considered “deterministic” if it always produces the same result for the same input parameters, and “not deterministic” otherwise. If neither `DETERMINISTIC` nor `NOT DETERMINISTIC` is given in the routine definition, the default is `NOT DETERMINISTIC`.

A routine that contains the `NOW()` function (or its synonyms) or `RAND()` is non-deterministic, but it might still be replication-safe. For `NOW()`, the binary log includes the timestamp and replicates correctly. `RAND()` also replicates correctly as long as it is invoked only once within a routine. (You can consider the routine execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

Currently, the **DETERMINISTIC** characteristic is accepted, but not yet used by the optimizer. However, if binary logging is enabled, this characteristic affects which routine definitions MySQL accepts. See [Section 19.4, “Binary Logging of Stored Routines and Triggers”](#).

Several characteristics provide information about the nature of data use by the routine. In MySQL, these characteristics are advisory only. The server does not use them to constrain what kinds of statements a routine will be allowed to execute.

- **CONTAINS SQL** indicates that the routine does not contain statements that read or write data. This is the default if none of these characteristics is given explicitly. Examples of such statements are **SET @x = 1** or **DO RELEASE_LOCK('abc')**, which execute but neither read nor write data.
- **NO SQL** indicates that the routine contains no SQL statements.
- **READS SQL DATA** indicates that the routine contains statements that read data (for example, **SELECT**), but not statements that write data.
- **MODIFIES SQL DATA** indicates that the routine contains statements that may write data (for example, **INSERT** or **DELETE**).

The **SQL SECURITY** characteristic can be used to specify whether the routine should be executed using the permissions of the user who creates the routine or the user who invokes it. The default value is **DEFINER**. This feature is new in SQL:2003. The creator or invoker must have permission to access the database with which the routine is associated. It is necessary to have the **EXECUTE** privilege to be able to execute the routine. The user that must have this privilege is either the definer or invoker, depending on how the **SQL SECURITY** characteristic is set.

The optional **DEFINER** clause specifies the MySQL account to be used when checking access privileges at routine execution time for routines that have the **SQL SECURITY DEFINER** characteristic. The **DEFINER** clause was added in MySQL 5.1.8.

If a *user* value is given, it should be a MySQL account in '*user_name*'@'*host_name*' format (the same format used in the **GRANT** statement). The *user_name* and *host_name* values both are required. **CURRENT_USER** also can be given as **CURRENT_USER()**. The default **DEFINER** value is the user who executes the **CREATE PROCEDURE** or **CREATE FUNCTION** or statement. (This is the same as **DEFINER = CURRENT_USER**.)

If you specify the **DEFINER** clause, you cannot set the value to any account but your own unless you have the **SUPER** privilege. These rules determine the legal **DEFINER** user values:

- If you do not have the **SUPER** privilege, the only legal *user* value is your own account, either specified literally or by using **CURRENT_USER**. You cannot set the definer to some other account.
- If you have the **SUPER** privilege, you can specify any syntactically legal account name. If the account does not actually exist, a warning is generated.

Although it is possible to create routines with a non-existent **DEFINER** value, an error occurs if the routine executes with definer privileges but the definer does not exist at execution time.

When the routine is invoked, an implicit **USE db_name** is performed (and undone when the routine terminates). **USE** statements within stored routines are disallowed.

The server uses the data type of a routine parameter or function return value as follows. These rules also apply to local routine variables created with the **DECLARE** statement ([Section 19.2.7.1, “DECLARE Local Variables”](#)).

- Assignments are checked for data type mismatches and overflow. Conversion and overflow problems result in warnings, or errors in strict mode.
- For character data types, if there is a **CHARACTER SET** clause in the declaration, the specified character set and its default collation are used. If there is no such clause, the database character set and collation that are in effect at the time the routine is created are used. (These are given by the values of the **character_set_database** and **collation_database** system variables.) The **COLLATE** attribute is not supported. (This includes use of **BINARY**, because in this context **BINARY** specifies the binary collation of the character set.)
- Only scalar values can be assigned to parameters or variables. For example, a statement such as **SET x = (SELECT 1, 2)** is invalid.

The **COMMENT** clause is a MySQL extension, and may be used to describe the stored routine. This information is displayed by the **SHOW CREATE PROCEDURE** and **SHOW CREATE FUNCTION** statements.

MySQL allows routines to contain DDL statements, such as **CREATE** and **DROP**. MySQL also allows stored procedures (but not stored functions) to contain SQL transaction statements such as **COMMIT**. Stored functions may not contain statements that do explicit or implicit commit or rollback. Support for these statements is not required by the SQL standard, which states that each DBMS vendor may decide whether to allow them.

Stored routines cannot use **LOAD DATA INFILE**.

Statements that return a result set cannot be used within a stored function. This includes **SELECT** statements that do not use **INTO** to fetch column values into variables, **SHOW** statements, and other statements such as **EXPLAIN**. For statements that can be determined at function definition time to return a result set, a **Not allowed to return a result set from a function** error occurs (**ER_SP_NO_RETSET**). For statements that can be determined only at runtime to return a result set, a **PROCEDURE %s can't return a result set in the given context** error occurs (**ER_SP_BADSELECT**).

The following is an example of a simple stored procedure that uses an **OUT** parameter. The example uses the **mysql** client **delimiter** command to change the statement delimiter from **;** to **//** while the procedure is being defined. This allows the **;** delimiter used in the procedure body to be passed through to the server rather than being interpreted by **mysql** itself.

```
mysql> delimiter //
mysql> CREATE PROCEDURE simpleproc (OUT param1 INT)
-> BEGIN
->   SELECT COUNT(*) INTO param1 FROM t;
-> END;
-> //
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter ;
mysql> CALL simpleproc(@a);
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @a;
+-----+
| @a    |
+-----+
| 3     |
+-----+
1 row in set (0.00 sec)
```

When using the **delimiter** command, you should avoid the use of the backslash (****) character because that is the escape character for MySQL.

The following is an example of a function that takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use **delimiter** because the function definition contains no internal **;** statement delimiters:

```
mysql> CREATE FUNCTION hello (s CHAR(20)) RETURNS CHAR(50)
-> RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT hello('world');
+-----+
| hello('world') |
+-----+
| Hello, world!  |
+-----+
1 row in set (0.00 sec)
```

For information about invoking stored procedures from within programs written in a language that has a MySQL interface, see [Section 19.2.4, “CALL Statement Syntax”](#).

19.2.2. ALTER PROCEDURE and ALTER FUNCTION Syntax

```
ALTER {PROCEDURE | FUNCTION} sp_name [characteristic ...]

characteristic:
{ CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
| SQL SECURITY { DEFINER | INVOKER }
| COMMENT 'string'
```

This statement can be used to change the characteristics of a stored procedure or function. You must have the **ALTER ROUTINE** priv-

ilege for the routine. (That privilege is granted automatically to the routine creator.) If binary logging is enabled, the **ALTER FUNCTION** statement might also require the **SUPER** privilege, as described in [Section 19.4, “Binary Logging of Stored Routines and Triggers”](#).

More than one change may be specified in an **ALTER PROCEDURE** or **ALTER FUNCTION** statement.

19.2.3. DROP PROCEDURE and DROP FUNCTION Syntax

```
DROP {PROCEDURE | FUNCTION} [IF EXISTS] sp_name
```

This statement is used to drop a stored procedure or function. That is, the specified routine is removed from the server. You must have the **ALTER ROUTINE** privilege for the routine. (That privilege is granted automatically to the routine creator.)

The **IF EXISTS** clause is a MySQL extension. It prevents an error from occurring if the procedure or function does not exist. A warning is produced that can be viewed with **SHOW WARNINGS**.

19.2.4. CALL Statement Syntax

```
CALL sp_name( [parameter [, ...]] )
CALL sp_name( )
```

The **CALL** statement invokes a procedure that was defined previously with **CREATE PROCEDURE**.

CALL can pass back values to its caller using parameters that are declared as **OUT** or **INOUT** parameters. It also “returns” the number of rows affected, which a client program can obtain at the SQL level by calling the **ROW_COUNT()** function and from C by calling the **mysql_affected_rows()** C API function.

As of MySQL 5.1.13, stored procedures that take no arguments now can be invoked without parentheses. That is, **CALL p()** and **CALL p** are equivalent.

To get back a value from a procedure using an **OUT** or **INOUT** parameter, pass the parameter by means of a user variable, and then check the value of the variable after the procedure returns. (If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an **IN** or **INOUT** parameter.) For an **INOUT** parameter, initialize its value before passing it to the procedure. The following procedure has an **OUT** parameter that the procedure sets to the current server version, and an **INOUT** value that the procedure increments by one from its current value:

```
CREATE PROCEDURE p (OUT ver_param VARCHAR(25), INOUT incr_param INT)
BEGIN
  # Set value of OUT parameter
  SELECT VERSION() INTO ver_param;
  # Increment value of INOUT parameter
  SET incr_param = incr_param + 1;
END;
```

Before calling the procedure, initialize the variable to be passed as the **INOUT** parameter. After calling the procedure, the values of the two variables will have been set or modified:

```
mysql> SET @increment = 10;
mysql> CALL p(@version, @increment);
mysql> SELECT @version, @increment;
+-----+-----+
| @version | @increment |
+-----+-----+
| 5.1.12-beta-log | 11 |
+-----+-----+
```

If you write C programs that use the **CALL** SQL statement to execute stored procedures that produce result sets, you *must* set the **CLIENT_MULTI_RESULTS** flag, either explicitly, or implicitly by setting **CLIENT_MULTI_STATEMENTS** when you call **mysql_real_connect()**. This is because each such stored procedure produces multiple results: the result sets returned by statements executed within the procedure, as well as a result to indicate the call status. To process the result of a **CALL** statement, use a loop that calls **mysql_next_result()** to determine whether there are more results. For an example, see [Section 25.2.9, “C API Handling of Multiple Statement Execution”](#).

For programs written in a language that provides a MySQL interface, there is no native method for directly retrieving the results of **OUT** or **INOUT** parameters from **CALL** statements. To get the parameter values, pass user-defined variables to the procedure in the **CALL** statement and then execute a **SELECT** statement to produce a result set containing the variable values. The following example illustrates the technique (without error checking) for a stored procedure **p1** that has two **OUT** parameters.

```
mysql_query(mysql, "CALL p1(@param1, @param2)");
mysql_query(mysql, "SELECT @param1, @param2");
result = mysql_store_result(mysql);
row = mysql_fetch_row(result);
mysql_free_result(result);
```

After the preceding code executes, `row[0]` and `row[1]` contain the values of `@param1` and `@param2`, respectively.

To handle **INOUT** parameters, execute a statement prior to the **CALL** that sets the user variables to the values to be passed to the procedure.

19.2.5. **BEGIN ... END** Compound Statement Syntax

```
[begin_label:] BEGIN
[statement_list]
END [end_label]
```

BEGIN ... END syntax is used for writing compound statements, which can appear within stored routines and triggers. A compound statement can contain multiple statements, enclosed by the **BEGIN** and **END** keywords. *statement_list* represents a list of one or more statements. Each statement within *statement_list* must be terminated by a semicolon (`;`) statement delimiter. Note that *statement_list* is optional, which means that the empty compound statement (**BEGIN END**) is legal.

Use of multiple statements requires that a client is able to send statement strings containing the `;` statement delimiter. This is handled in the **mysql** command-line client with the **delimiter** command. Changing the `;` end-of-statement delimiter (for example, to `//`) allows `;` to be used in a routine body. For an example, see [Section 19.2.1, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#).

A compound statement can be labeled. *end_label* cannot be given unless *begin_label* also is present. If both are present, they must be the same.

The optional **[NOT] ATOMIC** clause is not yet supported. This means that no transactional savepoint is set at the start of the instruction block and the **BEGIN** clause used in this context has no effect on the current transaction.

19.2.6. **DECLARE** Statement Syntax

The **DECLARE** statement is used to define various items local to a routine:

- Local variables. See [Section 19.2.7, “Variables in Stored Routines”](#).
- Conditions and handlers. See [Section 19.2.8, “Conditions and Handlers”](#).
- Cursors. See [Section 19.2.9, “Cursors”](#).

The **SIGNAL** and **RESIGNAL** statements are not currently supported.

DECLARE is allowed only inside a **BEGIN ... END** compound statement and must be at its start, before any other statements.

Declarations must follow a certain order. Cursors must be declared before declaring handlers, and variables and conditions must be declared before declaring either cursors or handlers.

19.2.7. Variables in Stored Routines

You may declare and use variables within a routine.

19.2.7.1. **DECLARE** Local Variables

```
DECLARE var_name[, ...] type [DEFAULT value]
```

This statement is used to declare local variables. To provide a default value for the variable, include a **DEFAULT** clause. The value can be specified as an expression; it need not be a constant. If the **DEFAULT** clause is missing, the initial value is **NULL**.

Local variables are treated like routine parameters with respect to data type and overflow checking. See [Section 19.2.1, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#).

The scope of a local variable is within the **BEGIN ... END** block where it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

19.2.7.2. Variable **SET** Statement

```
SET var_name = expr [, var_name = expr] ...
```

The **SET** statement in stored routines is an extended version of the general **SET** statement. Referenced variables may be ones declared inside a routine, or global system variables.

The **SET** statement in stored routines is implemented as part of the pre-existing **SET** syntax. This allows an extended syntax of **SET a=x, b=y, ...** where different variable types (locally declared variables and global and session server variables) can be mixed. This also allows combinations of local variables and some options that make sense only for system variables; in that case, the options are recognized but ignored.

19.2.7.3. **SELECT ... INTO** Statement

```
SELECT col_name [, ...] INTO var_name [, ...] table_expr
```

This **SELECT** syntax stores selected columns directly into variables. Therefore, only a single row may be retrieved.

```
SELECT id,data INTO x,y FROM test.t1 LIMIT 1;
```

User variable names are not case sensitive. See [Section 8.4, “User-Defined Variables”](#).

Important

SQL variable names should not be the same as column names. If an SQL statement, such as a **SELECT ... INTO** statement, contains a reference to a column and a declared local variable with the same name, MySQL currently interprets the reference as the name of a variable. For example, in the following statement, **xname** is interpreted as a reference to the **xname** variable rather than the **xname** column:

```
CREATE PROCEDURE sp1 (x VARCHAR(5))
BEGIN
  DECLARE xname VARCHAR(5) DEFAULT 'bob';
  DECLARE newname VARCHAR(5);
  DECLARE xid INT;

  SELECT xname,id INTO newname,xid
    FROM table1 WHERE xname = xname;
  SELECT newname;
END;
```

When this procedure is called, the **newname** variable returns the value **'bob'** regardless of the value of the **table1.xname** column.

See also [Section D.1, “Restrictions on Stored Routines and Triggers”](#).

19.2.8. Conditions and Handlers

Certain conditions may require specific handling. These conditions can relate to errors, as well as to general flow control inside a routine.

19.2.8.1. **DECLARE** Conditions

```
DECLARE condition_name CONDITION FOR condition_value
condition_value:
  SQLSTATE [VALUE] sqlstate_value
  | mysql_error_code
```

This statement specifies conditions that need specific handling. It associates a name with a specified error condition. The name can subsequently be used in a **DECLARE HANDLER** statement. See [Section 19.2.8.2, “DECLARE Handlers”](#).

A **condition_value** can be an SQLSTATE value or a MySQL error code.

19.2.8.2. DECLARE Handlers

```
DECLARE handler_type HANDLER FOR condition_value[,...] statement

handler_type:
  CONTINUE
  | EXIT
  | UNDO

condition_value:
  SQLSTATE [VALUE] sqlstate_value
  | condition_name
  | SQLWARNING
  | NOT FOUND
  | SQLEXCEPTION
  | mysql_error_code
```

The **DECLARE ... HANDLER** statement specifies handlers that each may deal with one or more conditions. If one of these conditions occurs, the specified *statement* is executed. *statement* can be a simple statement (for example, **SET var_name = value**), or it can be a compound statement written using **BEGIN** and **END** (see [Section 19.2.5, “BEGIN ... END Compound Statement Syntax”](#)).

For a **CONTINUE** handler, execution of the current routine continues after execution of the handler statement. For an **EXIT** handler, execution terminates for the **BEGIN ... END** compound statement in which the handler is declared. (This is true even if the condition occurs in an inner block.) The **UNDO** handler type statement is not yet supported.

If a condition occurs for which no handler has been declared, the default action is **EXIT**.

A *condition_value* can be any of the following values:

- An SQLSTATE value or a MySQL error code.
- A condition name previously specified with **DECLARE ... CONDITION**. See [Section 19.2.8.1, “DECLARE Conditions”](#).
- **SQLWARNING** is shorthand for all SQLSTATE codes that begin with **01**.
- **NOT FOUND** is shorthand for all SQLSTATE codes that begin with **02**.
- **SQLEXCEPTION** is shorthand for all SQLSTATE codes not caught by **SQLWARNING** or **NOT FOUND**.

Example:

```
mysql> CREATE TABLE test.t (s1 int,primary key (s1));
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter //

mysql> CREATE PROCEDURE handlerdemo ()
-> BEGIN
->   DECLARE CONTINUE HANDLER FOR SQLSTATE '23000' SET @x2 = 1;
->   SET @x = 1;
->   INSERT INTO test.t VALUES (1);
->   SET @x = 2;
->   INSERT INTO test.t VALUES (1);
->   SET @x = 3;
-> END;
-> //
Query OK, 0 rows affected (0.00 sec)

mysql> CALL handlerdemo();//
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x//
+-----+
| @x    |
+-----+
| 3     |
+-----+
1 row in set (0.00 sec)
```

The example associates a handler with SQLSTATE 23000, which occurs for a duplicate-key error. Notice that **@x** is **3**, which shows that MySQL executed to the end of the procedure. If the line **DECLARE CONTINUE HANDLER FOR SQLSTATE '23000' SET @x2 = 1;** had not been present, MySQL would have taken the default path (**EXIT**) after the second **INSERT** failed due to the

PRIMARY KEY constraint, and **SELECT @x** would have returned 2.

If you want to ignore a condition, you can declare a **CONTINUE** handler for it and associate it with an empty block. For example:

```
DECLARE CONTINUE HANDLER FOR SQLWARNING BEGIN END;
```

The statement associated with a handler cannot use **ITERATE** or **LEAVE** to refer to labels for blocks that enclose the handler declaration. That is, the scope of a block label does not include the code for handlers declared within the block. Consider the following example, where the **REPEAT** block has a label of **retry**:

```
CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 3;
  retry:
  REPEAT
  BEGIN
    DECLARE CONTINUE HANDLER FOR SQLWARNING
    BEGIN
      ITERATE retry; # illegal
    END;
  END;
  IF i < 0 THEN
    LEAVE retry;      # legal
  END IF;
  SET i = i - 1;
  UNTIL FALSE END REPEAT;
END;
```

The label is in scope for the **IF** statement within the block. It is not in scope for the **CONTINUE** handler, so the reference there is invalid and results in an error:

```
ERROR 1308 (42000): LEAVE with no matching label: retry
```

To avoid using references to outer labels in handlers, you can use different strategies:

- If you want to leave the block, you can use an **EXIT** handler:

```
DECLARE EXIT HANDLER FOR SQLWARNING BEGIN END;
```

- If you want to iterate, you can set a status variable in the handler that can be checked in the enclosing block to determine whether the handler was invoked. The following example uses the variable **done** for this purpose:

```
CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 3;
  DECLARE done INT DEFAULT FALSE;
  retry:
  REPEAT
  BEGIN
    DECLARE CONTINUE HANDLER FOR SQLWARNING
    BEGIN
      SET done = TRUE;
    END;
  END;
  IF NOT done AND i < 0 THEN
    LEAVE retry;
  END IF;
  SET i = i - 1;
  UNTIL FALSE END REPEAT;
END;
```

19.2.9. Cursors

Cursors are supported inside stored procedures and functions and triggers. The syntax is as in embedded SQL. Cursors are currently asensitive, read-only, and non-scrolling. Asensitive means that the server may or may not make a copy of its result table.

Cursors must be declared before declaring handlers, and variables and conditions must be declared before declaring either cursors or handlers.

Example:

```

CREATE PROCEDURE curdemo()
BEGIN
  DECLARE done INT DEFAULT 0;
  DECLARE a CHAR(16);
  DECLARE b,c INT;
  DECLARE cur1 CURSOR FOR SELECT id,data FROM test.t1;
  DECLARE cur2 CURSOR FOR SELECT i FROM test.t2;
  DECLARE CONTINUE HANDLER FOR SQLSTATE '02000' SET done = 1;

  OPEN cur1;
  OPEN cur2;

  REPEAT
    FETCH cur1 INTO a, b;
    FETCH cur2 INTO c;
    IF NOT done THEN
      IF b < c THEN
        INSERT INTO test.t3 VALUES (a,b);
      ELSE
        INSERT INTO test.t3 VALUES (a,c);
      END IF;
    END IF;
  UNTIL done END REPEAT;

  CLOSE cur1;
  CLOSE cur2;
END

```

19.2.9.1. Declaring Cursors

```
DECLARE cursor_name CURSOR FOR select_statement
```

This statement declares a cursor. Multiple cursors may be declared in a routine, but each cursor in a given block must have a unique name.

The **SELECT** statement cannot have an **INTO** clause.

19.2.9.2. Cursor **OPEN** Statement

```
OPEN cursor_name
```

This statement opens a previously declared cursor.

19.2.9.3. Cursor **FETCH** Statement

```
FETCH cursor_name INTO var_name [, var_name] ...
```

This statement fetches the next row (if a row exists) using the specified open cursor, and advances the cursor pointer.

If no more rows are available, a No Data condition occurs with SQLSTATE value 02000. To detect this condition, you can set up a handler for it. An example is shown in [Section 19.2.9, “Cursors”](#).

19.2.9.4. Cursor **CLOSE** Statement

```
CLOSE cursor_name
```

This statement closes a previously opened cursor.

If not closed explicitly, a cursor is closed at the end of the compound statement in which it was declared.

19.2.10. Flow Control Constructs

The **IF**, **CASE**, **LOOP**, **WHILE**, **REPEAT**, **ITERATE**, and **LEAVE** constructs are fully implemented.

Many of these constructs contain other statements, as indicated by the grammar specifications in the following sections. Such constructs may be nested. For example, an **IF** statement might contain a **WHILE** loop, which itself contains a **CASE** statement.

FOR loops are not currently supported.

19.2.10.1. IF Statement

```
IF search_condition THEN statement_list
  [ELSEIF search_condition THEN statement_list] ...
  [ELSE statement_list]
END IF
```

IF implements a basic conditional construct. If the *search_condition* evaluates to true, the corresponding SQL statement list is executed. If no *search_condition* matches, the statement list in the **ELSE** clause is executed. Each *statement_list* consists of one or more statements.

Note

There is also an **IF()** function, which differs from the **IF statement** described here. See [Section 11.3, “Control Flow Functions”](#).

19.2.10.2. CASE Statement

```
CASE case_value
  WHEN when_value THEN statement_list
  [WHEN when_value THEN statement_list] ...
  [ELSE statement_list]
END CASE
```

Or:

```
CASE
  WHEN search_condition THEN statement_list
  [WHEN search_condition THEN statement_list] ...
  [ELSE statement_list]
END CASE
```

The **CASE** statement for stored routines implements a complex conditional construct. If a *search_condition* evaluates to true, the corresponding SQL statement list is executed. If no search condition matches, the statement list in the **ELSE** clause is executed. Each *statement_list* consists of one or more statements.

Note

The syntax of the **CASE statement** shown here for use inside stored routines differs slightly from that of the SQL **CASE expression** described in [Section 11.3, “Control Flow Functions”](#). The **CASE** statement cannot have an **ELSE NULL** clause, and it is terminated with **END CASE** instead of **END**.

19.2.10.3. LOOP Statement

```
[begin_label:] LOOP
  statement_list
END LOOP [end_label]
```

LOOP implements a simple loop construct, enabling repeated execution of the statement list, which consists of one or more statements. The statements within the loop are repeated until the loop is exited; usually this is accomplished with a **LEAVE** statement.

A **LOOP** statement can be labeled. *end_label* cannot be given unless *begin_label* also is present. If both are present, they must be the same.

19.2.10.4. LEAVE Statement

```
LEAVE label
```

This statement is used to exit any labeled flow control construct. It can be used within **BEGIN . . . END** or loop constructs (**LOOP**, **REPEAT**, **WHILE**).

19.2.10.5. ITERATE Statement

```
ITERATE label
```

ITERATE can appear only within **LOOP**, **REPEAT**, and **WHILE** statements. **ITERATE** means “do the loop again.”

Example:

```
CREATE PROCEDURE doitrate(p1 INT)
BEGIN
  label1: LOOP
    SET p1 = p1 + 1;
    IF p1 < 10 THEN ITERATE label1; END IF;
    LEAVE label1;
  END LOOP label1;
  SET @x = p1;
END
```

19.2.10.6. REPEAT Statement

```
[begin_label:] REPEAT
  statement_list
UNTIL search_condition
END REPEAT [end_label]
```

The statement list within a **REPEAT** statement is repeated until the *search_condition* is true. Thus, a **REPEAT** always enters the loop at least once. *statement_list* consists of one or more statements.

A **REPEAT** statement can be labeled. *end_label* cannot be given unless *begin_label* also is present. If both are present, they must be the same.

Example:

```
mysql> delimiter //
mysql> CREATE PROCEDURE dorepeat(p1 INT)
-> BEGIN
->   SET @x = 0;
->   REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
-> END
-> //
Query OK, 0 rows affected (0.00 sec)

mysql> CALL dorepeat(1000)//
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x//
+-----+
| @x    |
+-----+
| 1001  |
+-----+
1 row in set (0.00 sec)
```

19.2.10.7. WHILE Statement

```
[begin_label:] WHILE search_condition DO
  statement_list
END WHILE [end_label]
```

The statement list within a **WHILE** statement is repeated as long as the *search_condition* is true. *statement_list* consists of one or more statements.

A **WHILE** statement can be labeled. *end_label* cannot be given unless *begin_label* also is present. If both are present, they must be the same.

Example:

```
CREATE PROCEDURE dowhile()
BEGIN
  DECLARE v1 INT DEFAULT 5;

  WHILE v1 > 0 DO
    SET v1 = v1 - 1;
  END WHILE;
END
```

19.3. Stored Procedures, Functions, Triggers, and `LAST_INSERT_ID()`

Within the body of a stored routine (procedure or function) or a trigger, the value of `LAST_INSERT_ID()` changes the same way as for statements executed outside the body of these kinds of objects (see [Section 11.11.3, “Information Functions”](#)). The effect of a stored routine or trigger upon the value of `LAST_INSERT_ID()` that is seen by following statements depends on the kind of routine:

- If a stored procedure executes statements that change the value of `LAST_INSERT_ID()`, the changed value will be seen by statements that follow the procedure call.
- For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so following statements will not see a changed value.

19.4. Binary Logging of Stored Routines and Triggers

The binary log contains information about SQL statements that modify database contents. This information is stored in the form of “events” that describe the modifications. The binary log has two important purposes:

- For replication, the master server sends the events contained in its binary log to its slaves, which execute those events to make the same data changes that were made on the master. See [Section 15.4, “Replication Implementation”](#).
- Certain data recovery operations require use of the binary log. After a backup file has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See [Section 5.9.2.2, “Using Backups for Recovery”](#).

This section describes how MySQL 5.1 handles binary logging for stored routines (procedures and functions) and triggers. It also states the current conditions that the implementation places on the use of stored routines, and then provides additional information about the reasons for these conditions.

In general, the issues described here result when binary logging occurs at the SQL statement level. If you use row-based binary logging, the log contains changes made to individual rows as a result of executing SQL statements. For general information about row-based logging, see [Section 15.1.2, “Replication Formats”](#).

When using row-based logging, definitions of stored routines and triggers are replicated as statements. When routines or triggers execute, row changes are logged, not the statements that execute them. For stored procedures, this means that the `CALL` statement is not logged. For stored functions, row changes made within the function are logged, not the function invocation. For triggers, row changes made by the trigger are logged. On the slave side, only the row changes are seen, not the routine or trigger invocation.

Unless noted otherwise, the remarks here assume that you have enabled binary logging by starting the server with the `--log-bin` option. (See [Section 5.11.4, “The Binary Log”](#).) If the binary log is not enabled, replication is not possible, nor is the binary log available for data recovery.

The current conditions on the use of stored functions in MySQL 5.1 can be summarized as follows. These conditions do not apply to stored procedures and they do not apply unless binary logging is enabled.

- To create or alter a stored function, you must have the `SUPER` privilege, in addition to the `CREATE ROUTINE` or `ALTER ROUTINE` privilege that is normally required.
- When you create a stored function, you must declare either that it is deterministic or that it does not modify data. Otherwise, it may be unsafe for data recovery or replication.
- To relax the preceding conditions on function creation (that you must have the `SUPER` privilege and that a function must be declared deterministic or to not modify data), set the global `log_bin_trust_function_creators` system variable to 1. By default, this variable has a value of 0, but you can change it like this:

```
mysql> SET GLOBAL log_bin_trust_function_creators = 1;
```

You can also set this variable by using the `--log-bin-trust-function-creators=1` option when starting the server.

If binary logging is not enabled, `log_bin_trust_function_creators` does not apply and `SUPER` is not required for function creation.

Triggers are similar to stored functions, so the preceding remarks regarding functions also apply to triggers with the following exception: **CREATE TRIGGER** does not have an optional **DETERMINISTIC** characteristic, so triggers are assumed to be always deterministic. However, this assumption might in some cases be invalid. For example, the **UUID()** function is non-deterministic (and does not replicate). You should be careful about using such functions in triggers.

Triggers can update tables, so error messages similar to those for stored functions occur with **CREATE TRIGGER** if you do not have the **TRIGGER** privilege (**SUPER** before MySQL 5.1.6) and **log_bin_trust_function_creators** is 0. (On the slave side, the slave uses the trigger **DEFINER** attribute to determine which user is considered to be the creator of the trigger.)

The following discussion provides additional detail about the logging implementation and its implications. This discussion applies only for statement-based logging, and not for row-based logging, with the exception of the first item: **CREATE** and **DROP** statements are logged as statements regardless of the logging mode.

- The server writes **CREATE PROCEDURE**, **CREATE FUNCTION**, **ALTER PROCEDURE**, **ALTER FUNCTION**, **DROP PROCEDURE**, and **DROP FUNCTION** statements to the binary log.
- A stored function invocation is logged as a **SELECT** statement if the function changes data and occurs within a statement that would not otherwise be logged. This prevents non-replication of data changes that result from use of stored functions in non-logged statements. For example, **SELECT** statements are not written to the binary log, but a **SELECT** might invoke a stored function that makes changes. To handle this, a **SELECT func_name()** statement is written to the binary log when the given function makes a change. Suppose that the following statements are executed on the master:

```
CREATE FUNCTION f1(a INT) RETURNS INT
BEGIN
  IF (a < 3) THEN
    INSERT INTO t2 VALUES (a);
  END IF;
END;

CREATE TABLE t1 (a INT);
INSERT INTO t1 VALUES (1),(2),(3);

SELECT f1(a) FROM t1;
```

When the **SELECT** statement executes, the function **f1()** is invoked three times. Two of those invocations insert a row, and MySQL logs a **SELECT** statement for each of them. That is, MySQL writes the following statements to the binary log:

```
SELECT f1(1);
SELECT f1(2);
```

The server also logs a **SELECT** statement for a stored function invocation when the function invokes a stored procedure that causes an error. In this case, the server writes the **SELECT** statement to the log along with the expected error code. On the slave, if the same error occurs, that is the expected result and replication continues. Otherwise, replication stops.

Note: Before MySQL 5.1.7, you will see these **SELECT func_name()** statements logged as **DO func_name()**. The change to **SELECT** was made because use of **DO** was found to yield insufficient control over error code checking.

- Logging stored function invocations rather than the statements executed by a function has a security implication for replication, which arises from two factors:
 - It is possible for a function to follow different execution paths on master and slave servers.
 - Statements executed on a slave are processed by the slave SQL thread which has full privileges.

The implication is that although a user must have the **CREATE ROUTINE** privilege to create a function, the user can write a function containing a dangerous statement that will execute only on the slave where the statement is processed by the SQL thread that has full privileges. For example, if the master and slave servers have server ID values of 1 and 2, respectively, a user on the master server could create and invoke an unsafe function **unsafe_func()** as follows:

```
mysql> delimiter //
mysql> CREATE FUNCTION unsafe_func () RETURNS INT
-> BEGIN
->   IF @@server_id=2 THEN dangerous_statement; END IF;
->   RETURN 1;
-> END;
-> //
mysql> delimiter ;
mysql> INSERT INTO t VALUES(unsafe_func());
```

The `CREATE FUNCTION` and `INSERT` statements are written to the binary log, so the slave will execute them. Because the slave SQL thread has full privileges, it will execute the dangerous statement. Thus, the function invocation has different effects on the master and slave and is not replication-safe.

To guard against this danger for servers that have binary logging enabled, stored function creators must have the `SUPER` privilege, in addition to the usual `CREATE ROUTINE` privilege that is required. Similarly, to use `ALTER FUNCTION`, you must have the `SUPER` privilege in addition to the `ALTER ROUTINE` privilege. Without the `SUPER` privilege, an error will occur:

```
ERROR 1419 (HY000): You do not have the SUPER privilege and
binary logging is enabled (you *might* want to use the less safe
log_bin_trust_function_creators variable)
```

If you do not want to require function creators to have the `SUPER` privilege (for example, if all users with the `CREATE ROUTINE` privilege on your system are experienced application developers), set the global `log_bin_trust_function_creators` system variable to 1. You can also set this variable by using the `--log-bin-trust-function-creators=1` option when starting the server. If binary logging is not enabled, `log_bin_trust_function_creators` does not apply and `SUPER` is not required for function creation.

- If a function that performs updates is non-deterministic, it is not repeatable. This can have two undesirable effects:
 - It will make a slave different from the master.
 - Restored data will be different from the original data.

To deal with these problems, MySQL enforces the following requirement: On a master server, creation and alteration of a function is refused unless you declare the function to be deterministic or to not modify data. Two sets of function characteristics apply here:

- The `DETERMINISTIC` and `NOT DETERMINISTIC` characteristics indicate whether a function always produces the same result for given inputs. The default is `NOT DETERMINISTIC` if neither characteristic is given. To declare that a function is deterministic, you must specify `DETERMINISTIC` explicitly.

Use of the `NOW()` function (or its synonyms) or `RAND()` does not necessarily make a function non-deterministic. For `NOW()`, the binary log includes the timestamp and replicates correctly. `RAND()` also replicates correctly as long as it is invoked only once within a function. (You can consider the function execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

`SYSDATE()` is not affected by the timestamps in the binary log, so it causes stored routines to be non-deterministic if statement-based logging is used. This does not occur if row-based logging is used, or if the server is started with the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`.

- The `CONTAINS SQL`, `NO SQL`, `READS SQL DATA`, and `MODIFIES SQL DATA` characteristics provide information about whether the function reads or writes data. Either `NO SQL` or `READS SQL DATA` indicates that a function does not change data, but you must specify one of these explicitly because the default is `CONTAINS SQL` if no characteristic is given.

By default, for a `CREATE FUNCTION` statement to be accepted, `DETERMINISTIC` or one of `NO SQL` and `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL,
or READS SQL DATA in its declaration and binary logging is enabled
(you *might* want to use the less safe log_bin_trust_function_creators
variable)
```

If you set `log_bin_trust_function_creators` to 1, the requirement that functions be deterministic or not modify data is dropped.

Assessment of the nature of a function is based on the “honesty” of the creator: MySQL does not check that a function declared `DETERMINISTIC` is free of statements that produce non-deterministic results.

- Stored procedure calls are logged at the statement level rather than at the `CALL` level. That is, the server does not log the `CALL` statement, it logs those statements within the procedure that actually execute. As a result, the same changes that occur on the master will be observed on slave servers. This prevents problems that could result from a procedure having different execution paths on different machines.

In general, statements executed within a stored procedure are written to the binary log using the same rules that would apply were the statements to be executed in standalone fashion. Some special care is taken when logging procedure statements because state-

ment execution within procedures is not quite the same as in non-procedure context:

- A statement to be logged might contain references to local procedure variables. These variables do not exist outside of stored procedure context, so a statement that refers to such a variable cannot be logged literally. Instead, each reference to a local variable is replaced by this construct for logging purposes:

```
NAME_CONST(var_name, var_value)
```

var_name is the local variable name, and *var_value* is a constant indicating the value that the variable has at the time the statement is logged. `NAME_CONST()` has a value of *var_value*, and a “name” of *var_name*. Thus, if you invoke this function directly, you get a result like this:

```
mysql> SELECT NAME_CONST('myname', 14);
+-----+
| myname |
+-----+
|      14 |
+-----+
```

`NAME_CONST()` allows a logged standalone statement to be executed on a slave with the same effect as the original statement that was executed on the master within a stored procedure.

- A statement to be logged might contain references to user-defined variables. To handle this, MySQL writes a `SET` statement to the binary log to make sure that the variable exists on the slave with the same value as on the master. For example, if a statement refers to a variable `@my_var`, that statement will be preceded in the binary log by the following statement, where *value* is the value of `@my_var` on the master:

```
SET @my_var = value;
```

- Procedure calls can occur within a committed or rolled-back transaction. Previously, `CALL` statements were logged even if they occurred within a rolled-back transaction. As of MySQL 5.0.12, transactional context is accounted for so that the transactional aspects of procedure execution are replicated correctly. That is, the server logs those statements within the procedure that actually execute and modify data, and also logs `BEGIN`, `COMMIT`, and `ROLLBACK` statements as necessary. For example, if a procedure updates only transactional tables and is executed within a transaction that is rolled back, those updates are not logged. If the procedure occurs within a committed transaction, `BEGIN` and `COMMIT` statements are logged with the updates. For a procedure that executes within a rolled-back transaction, its statements are logged using the same rules that would apply if the statements were executed in standalone fashion:
 - Updates to transactional tables are not logged.
 - Updates to non-transactional tables are logged because rollback does not cancel them.
 - Updates to a mix of transactional and non-transactional tables are logged surrounded by `BEGIN` and `ROLLBACK` so that slaves will make the same changes and rollbacks as on the master.
- A stored procedure call is *not* written to the binary log at the statement level if the procedure is invoked from within a stored function. In that case, the only thing logged is the statement that invokes the function (if it occurs within a statement that is logged) or a `DO` statement (if it occurs within a statement that is not logged). For this reason, care should be exercised in the use of stored functions that invoke a procedure, even if the procedure is otherwise safe in itself.

Chapter 20. Triggers

A trigger is a named database object that is associated with a table and that is activated when a particular event occurs for the table. For example, the following statements create a table and an `INSERT` trigger. The trigger sums the values inserted into one of the table's columns:

```
mysql> CREATE TABLE account (acct_num INT, amount DECIMAL(10,2));
Query OK, 0 rows affected (0.03 sec)

mysql> CREATE TRIGGER ins_sum BEFORE INSERT ON account
-> FOR EACH ROW SET @sum = @sum + NEW.amount;
Query OK, 0 rows affected (0.06 sec)
```

Important

MySQL triggers are activated by SQL statements *only*. They are not activated by changes in tables made by APIs that do not transmit SQL statements to the MySQL Server; in particular, they are not activated by updates made using the `NDB` API.

This chapter describes the syntax for creating and dropping triggers, and shows some examples of how to use them. Discussion of restrictions on use of triggers is given in [Section D.1, “Restrictions on Stored Routines and Triggers”](#). Remarks regarding binary logging as it applies to triggers are given in [Section 19.4, “Binary Logging of Stored Routines and Triggers”](#).

For answers to some common questions about triggers in MySQL 5.1, see [Section A.5, “MySQL 5.1 FAQ — Triggers”](#).

20.1. CREATE TRIGGER Syntax

```
CREATE
[DEFINER = { user | CURRENT_USER }]
TRIGGER trigger_name trigger_time trigger_event
ON tbl_name FOR EACH ROW trigger_stmt
```

This statement creates a new trigger. A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. Currently, `CREATE TRIGGER` requires the `TRIGGER` privilege for the table associated with the trigger. (This statement requires the `SUPER` privilege prior to MySQL 5.1.6.)

MySQL Enterprise

For expert advice on creating triggers subscribe to the MySQL Enterprise Monitor. For more information see <http://www.mysql.com/products/enterprise/advisors.html>.

The trigger becomes associated with the table named *tbl_name*, which must refer to a permanent table. You cannot associate a trigger with a `TEMPORARY` table or a view.

When the trigger is activated, the `DEFINER` clause determines the privileges that apply, as described later in this section.

trigger_time is the trigger action time. It can be `BEFORE` or `AFTER` to indicate that the trigger activates before or after the statement that activated it.

trigger_event indicates the kind of statement that activates the trigger. The *trigger_event* can be one of the following:

- **INSERT**: The trigger is activated whenever a new row is inserted into the table; for example, through `INSERT`, `LOAD DATA`, and `REPLACE` statements.
- **UPDATE**: The trigger is activated whenever a row is modified; for example, through `UPDATE` statements.
- **DELETE**: The trigger is activated whenever a row is deleted from the table; for example, through `DELETE` and `REPLACE` statements. However, `DROP TABLE` and `TRUNCATE` statements on the table do *not* activate this trigger, because they do not use `DELETE`. Dropping a partition does not activate `DELETE` triggers, either. See [Section 12.2.9, “TRUNCATE Syntax”](#).

It is important to understand that the *trigger_event* does not represent a literal type of SQL statement that activates the trigger so much as it represents a type of table operation. For example, an `INSERT` trigger is activated by not only `INSERT` statements but also `LOAD DATA` statements because both statements insert rows into a table.

A potentially confusing example of this is the `INSERT INTO ... ON DUPLICATE KEY UPDATE ...` syntax: a `BEFORE INSERT` trigger will activate for every row, followed by either an `AFTER INSERT` trigger or both the `BEFORE UPDATE` and `AFTER UPDATE` triggers, depending on whether there was a duplicate key for the row.

There cannot be two triggers for a given table that have the same trigger action time and event. For example, you cannot have two `BEFORE UPDATE` triggers for a table. But you can have a `BEFORE UPDATE` and a `BEFORE INSERT` trigger, or a `BEFORE UPDATE` and an `AFTER UPDATE` trigger.

`trigger_stmt` is the statement to execute when the trigger activates. If you want to execute multiple statements, use the `BEGIN ... END` compound statement construct. This also enables you to use the same statements that are allowable within stored routines. See [Section 19.2.5, “BEGIN ... END Compound Statement Syntax”](#). Some statements are not allowed in triggers; see [Section D.1, “Restrictions on Stored Routines and Triggers”](#).

MySQL stores the `sql_mode` system variable setting that is in effect at the time a trigger is created, and always executes the trigger with this setting in force, *regardless of the current server SQL mode*.

Note

Currently, triggers are not activated by cascaded foreign key actions. This limitation will be lifted as soon as possible.

In MySQL 5.1, you can write triggers containing direct references to tables by name, such as the trigger named `testref` shown in this example:

```
CREATE TABLE test1(a1 INT);
CREATE TABLE test2(a2 INT);
CREATE TABLE test3(a3 INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
CREATE TABLE test4(
  a4 INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  b4 INT DEFAULT 0
);
DELIMITER |

CREATE TRIGGER testref BEFORE INSERT ON test1
FOR EACH ROW BEGIN
  INSERT INTO test2 SET a2 = NEW.a1;
  DELETE FROM test3 WHERE a3 = NEW.a1;
  UPDATE test4 SET b4 = b4 + 1 WHERE a4 = NEW.a1;
END;
|
DELIMITER ;

INSERT INTO test3 (a3) VALUES
(NULL), (NULL), (NULL), (NULL), (NULL),
(NULL), (NULL), (NULL), (NULL), (NULL);

INSERT INTO test4 (a4) VALUES
(0), (0), (0), (0), (0), (0), (0), (0), (0), (0);
```

Suppose that you insert the following values into table `test1` as shown here:

```
mysql> INSERT INTO test1 VALUES
-> (1), (3), (1), (7), (1), (8), (4), (4);
Query OK, 8 rows affected (0.01 sec)
Records: 8 Duplicates: 0 Warnings: 0
```

As a result, the data in the four tables will be as follows:

```
mysql> SELECT * FROM test1;
+-----+
| a1    |
+-----+
| 1     |
| 3     |
| 1     |
| 7     |
| 1     |
| 8     |
| 4     |
| 4     |
+-----+
8 rows in set (0.00 sec)

mysql> SELECT * FROM test2;
+-----+
| a2    |
+-----+
```

```

+-----+
| 1 |
| 3 |
| 1 |
| 7 |
| 1 |
| 8 |
| 4 |
| 4 |
+-----+
8 rows in set (0.00 sec)

mysql> SELECT * FROM test3;
+-----+
| a3 |
+-----+
| 2 |
| 5 |
| 6 |
| 9 |
| 10 |
+-----+
5 rows in set (0.00 sec)

mysql> SELECT * FROM test4;
+-----+
| a4 | b4 |
+-----+
| 1 | 3 |
| 2 | 0 |
| 3 | 1 |
| 4 | 2 |
| 5 | 0 |
| 6 | 0 |
| 7 | 1 |
| 8 | 1 |
| 9 | 0 |
| 10 | 0 |
+-----+
10 rows in set (0.00 sec)

```

You can refer to columns in the subject table (the table associated with the trigger) by using the aliases `OLD` and `NEW`. `OLD.col_name` refers to a column of an existing row before it is updated or deleted. `NEW.col_name` refers to the column of a new row to be inserted or an existing row after it is updated.

The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at trigger activation time. If a `user` value is given, it should be a MySQL account in `'user_name'@'host_name'` format (the same format used in the `GRANT` statement). The `user_name` and `host_name` values both are required. `CURRENT_USER` also can be given as `CURRENT_USER()`. The default `DEFINER` value is the user who executes the `CREATE TRIGGER` statement. (This is the same as `DEFINER = CURRENT_USER`.)

If you specify the `DEFINER` clause, you cannot set the value to any account but your own unless you have the `SUPER` privilege. These rules determine the legal `DEFINER` user values:

- If you do not have the `SUPER` privilege, the only legal `user` value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.
- If you have the `SUPER` privilege, you can specify any syntactically legal account name. If the account does not actually exist, a warning is generated.

Although it is possible to create triggers with a non-existent `DEFINER` value, it is not a good idea for such triggers to be activated until the definer actually does exist. Otherwise, the behavior with respect to privilege checking is undefined.

Note: Prior to MySQL 5.1.6, MySQL requires the `SUPER` privilege for the use of `CREATE TRIGGER`, so only the second of the preceding rules applies. As of 5.1.6, `CREATE TRIGGER` requires the `TRIGGER` privilege and `SUPER` is required only to be able to set `DEFINER` to a value other than your own account.

MySQL checks trigger privileges like this:

- At `CREATE TRIGGER` time, the user that issues the statement must have the `TRIGGER` privilege. (`SUPER` prior to MySQL 5.1.6.)
- At trigger activation time, privileges are checked against the `DEFINER` user. This user must have these privileges:
 - The `TRIGGER` privilege. (`SUPER` prior to MySQL 5.1.6.)

- The **SELECT** privilege for the subject table if references to table columns occur via *OLD.col_name* or *NEW.col_name* in the trigger definition.
- The **UPDATE** privilege for the subject table if table columns are targets of **SET NEW.col_name = value** assignments in the trigger definition.
- Whatever other privileges normally are required for the statements executed by the trigger.

20.2. DROP TRIGGER Syntax

```
DROP TRIGGER [IF EXISTS] [schema_name.]trigger_name
```

This statement drops a trigger. The schema (database) name is optional. If the schema is omitted, the trigger is dropped from the default schema. **DROP TRIGGER** was added in MySQL 5.0.2. Its use requires the **TRIGGER** privilege for the table associated with the trigger. (This statement requires the **SUPER** privilege prior to MySQL 5.1.6.)

Use **IF EXISTS** to prevent an error from occurring for a trigger that does not exist. A **NOTE** is generated for a non-existent trigger when using **IF EXISTS**. See [Section 12.5.4.32, “SHOW WARNINGS Syntax”](#). The **IF EXISTS** clause was added in MySQL 5.1.14.

Note

When upgrading from a version of MySQL older than MySQL 5.0.10 to 5.0.10 or newer — including all MySQL 5.1 releases — you must drop all triggers *before upgrading* and re-create them afterward, or else **DROP TRIGGER** does not work after the upgrade. See [Section 2.11.1, “Upgrading from MySQL 5.0 to 5.1”](#), for a suggested upgrade procedure.

20.3. Using Triggers

This section discusses how to use triggers in MySQL 5.1 and some limitations regarding their use. Additional information about trigger limitations is given in [Section D.1, “Restrictions on Stored Routines and Triggers”](#).

A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. Some uses for triggers are to perform checks of values to be inserted into a table or to perform calculations on values involved in an update.

A trigger is associated with a table and is defined to activate when an **INSERT**, **DELETE**, or **UPDATE** statement for the table executes. A trigger can be set to activate either before or after the triggering statement. For example, you can have a trigger activate before each row that is deleted from a table or after each row that is updated.

Important

MySQL triggers are activated by SQL statements *only*. They are not activated by changes in tables made by APIs that do not transmit SQL statements to the MySQL Server; in particular, they are not activated by updates made using the **NDB** API.

To create a trigger or drop a trigger, use the **CREATE TRIGGER** or **DROP TRIGGER** statement. The syntax for these statements is described in [Section 20.1, “CREATE TRIGGER Syntax”](#), and [Section 20.2, “DROP TRIGGER Syntax”](#).

Here is a simple example that associates a trigger with a table for **INSERT** statements. It acts as an accumulator to sum the values inserted into one of the columns of the table.

The following statements create a table and a trigger for it:

```
mysql> CREATE TABLE account (acct_num INT, amount DECIMAL(10,2));
mysql> CREATE TRIGGER ins_sum BEFORE INSERT ON account
-> FOR EACH ROW SET @sum = @sum + NEW.amount;
```

The **CREATE TRIGGER** statement creates a trigger named *ins_sum* that is associated with the *account* table. It also includes clauses that specify the trigger activation time, the triggering event, and what to do with the trigger activates:

- The keyword **BEFORE** indicates the trigger action time. In this case, the trigger should activate before each row inserted into the table. The other allowable keyword here is **AFTER**.

- The keyword **INSERT** indicates the event that activates the trigger. In the example, **INSERT** statements cause trigger activation. You can also create triggers for **DELETE** and **UPDATE** statements.
- The statement following **FOR EACH ROW** defines the statement to execute each time the trigger activates, which occurs once for each row affected by the triggering statement. In the example, the triggered statement is a simple **SET** that accumulates the values inserted into the **amount** column. The statement refers to the column as **NEW.amount** which means “the value of the **amount** column to be inserted into the new row.”

To use the trigger, set the accumulator variable to zero, execute an **INSERT** statement, and then see what value the variable has afterward:

```
mysql> SET @sum = 0;
mysql> INSERT INTO account VALUES(137,14.98),(141,1937.50),(97,-100.00);
mysql> SELECT @sum AS 'Total amount inserted';
+-----+
| Total amount inserted |
+-----+
| 1852.48                |
+-----+
```

In this case, the value of **@sum** after the **INSERT** statement has executed is **14.98 + 1937.50 - 100**, or **1852.48**.

To destroy the trigger, use a **DROP TRIGGER** statement. You must specify the schema name if the trigger is not in the default schema:

```
mysql> DROP TRIGGER test.ins_sum;
```

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

In addition to the requirement that trigger names be unique for a schema, there are other limitations on the types of triggers you can create. In particular, you cannot have two triggers for a table that have the same activation time and activation event. For example, you cannot define two **BEFORE INSERT** triggers or two **AFTER UPDATE** triggers for a table. This should rarely be a significant limitation, because it is possible to define a trigger that executes multiple statements by using the **BEGIN . . . END** compound statement construct after **FOR EACH ROW**. (An example appears later in this section.)

The **OLD** and **NEW** keywords enable you to access columns in the rows affected by a trigger. (**OLD** and **NEW** are not case sensitive.) In an **INSERT** trigger, only **NEW.col_name** can be used; there is no old row. In a **DELETE** trigger, only **OLD.col_name** can be used; there is no new row. In an **UPDATE** trigger, you can use **OLD.col_name** to refer to the columns of a row before it is updated and **NEW.col_name** to refer to the columns of the row after it is updated.

A column named with **OLD** is read-only. You can refer to it (if you have the **SELECT** privilege), but not modify it. A column named with **NEW** can be referred to if you have the **SELECT** privilege for it. In a **BEFORE** trigger, you can also change its value with **SET NEW.col_name = value** if you have the **UPDATE** privilege for it. This means you can use a trigger to modify the values to be inserted into a new row or that are used to update a row.

In a **BEFORE** trigger, the **NEW** value for an **AUTO_INCREMENT** column is 0, not the automatically generated sequence number that will be generated when the new record actually is inserted.

OLD and **NEW** are MySQL extensions to triggers.

By using the **BEGIN . . . END** construct, you can define a trigger that executes multiple statements. Within the **BEGIN** block, you also can use other syntax that is allowed within stored routines such as conditionals and loops. However, just as for stored routines, if you use the **mysql** program to define a trigger that executes multiple statements, it is necessary to redefine the **mysql** statement delimiter so that you can use the **;** statement delimiter within the trigger definition. The following example illustrates these points. It defines an **UPDATE** trigger that checks the new value to be used for updating each row, and modifies the value to be within the range from 0 to 100. This must be a **BEFORE** trigger because the value needs to be checked before it is used to update the row:

```
mysql> delimiter //
mysql> CREATE TRIGGER upd_check BEFORE UPDATE ON account
-> FOR EACH ROW
-> BEGIN
-> IF NEW.amount < 0 THEN
-> SET NEW.amount = 0;
-> ELSEIF NEW.amount > 100 THEN
-> SET NEW.amount = 100;
-> END IF;
-> END; //
mysql> delimiter ;
```

It can be easier to define a stored procedure separately and then invoke it from the trigger using a simple `CALL` statement. This is also advantageous if you want to invoke the same routine from within several triggers.

There are some limitations on what can appear in statements that a trigger executes when activated:

- The trigger cannot use the `CALL` statement to invoke stored procedures that return data to the client or that use dynamic SQL. (Stored procedures are allowed to return data to the trigger through `OUT` or `INOUT` parameters.)
- The trigger cannot use statements that explicitly or implicitly begin or end a transaction such as `START TRANSACTION`, `COMMIT`, or `ROLLBACK`.

MySQL handles errors during trigger execution as follows:

- If a `BEFORE` trigger fails, the operation on the corresponding row is not performed.
- A `BEFORE` trigger is activated by the *attempt* to insert or modify the row, regardless of whether the attempt subsequently succeeds.
- An `AFTER` trigger is executed only if the `BEFORE` trigger (if any) and the row operation both execute successfully.
- An error during either a `BEFORE` or `AFTER` trigger results in failure of the entire statement that caused trigger invocation.
- For transactional tables, failure of a statement should cause rollback of all changes performed by the statement. Failure of a trigger causes the statement to fail, so trigger failure also causes rollback. For non-transactional tables, such rollback cannot be done, so although the statement fails, any changes performed prior to the point of the error remain in effect.

Chapter 21. Event Scheduler

This chapter describes the *MySQL Event Scheduler*, for which support was added in MySQL 5.1.6, and is divided into the following sections:

- [Section 21.1, “Event Scheduler Overview”](#), provides an introduction to and conceptual overview of MySQL Events.
- [Section 21.2, “Event Scheduler Syntax”](#), discusses the SQL commands introduced in MySQL 5.1.6 for creating, altering, and dropping MySQL Events.
- [Section 21.3, “Event Metadata”](#), shows how to obtain information about events and how this information is stored by the MySQL Server.
- [Section 21.5, “The Event Scheduler and MySQL Privileges”](#), discusses the privileges required to work with events and the ramifications that events have with regard to privileges when executing.
- [Section 21.6, “Event Scheduler Limitations and Restrictions”](#), describes the restrictions and limitations of MySQL's Event Scheduler implementation.

Additional Resources. You may find the [MySQL Event Scheduler User Forum](#) of use when working with scheduled events. Here you can discuss the MySQL Event Scheduler with other MySQL users and the MySQL developers.

21.1. Event Scheduler Overview

MySQL Events are tasks that run according to a schedule. Therefore, we sometimes refer to them as *scheduled* events. When you create an event, you are creating a named database object containing one or more SQL statements to be executed at one or more regular intervals, beginning and ending at a specific date and time. Conceptually, this is similar to the idea of the Unix [crontab](#) (also known as a “cron job”) or the Windows Task Scheduler.

Scheduled tasks of this type are also sometimes known as “temporal triggers”, implying that these are objects that are triggered by the passage of time. While this is essentially correct, we prefer to use the term *events* in order to avoid confusion with triggers of the type discussed in [Chapter 20, Triggers](#). Events should more specifically not be confused with “temporary triggers”. Whereas a trigger is a database object whose statements are executed in response to a specific type of event that occurs on a given table, a (scheduled) event is an object whose statements are executed in response to the passage of a specified time interval.

While there is no provision in the SQL Standard for event scheduling, there are precedents in other database systems, and you may notice some similarities between these implementations and that found in the MySQL Server.

MySQL Events have the following major features and properties:

- In MySQL 5.1.12 and later, an event is uniquely identified by its name and the schema to which it is assigned. (Previously, an event was also unique to its definer.)
- An event performs a specific action according to a schedule. This action consists of an SQL statement, which can be a compound statement in a [BEGIN . . . END](#) block if desired (see [Section 19.2.5, “BEGIN . . . END Compound Statement Syntax”](#)). An event's timing can be either *one-time* or *recurrent*. A one-time event executes one time only. A recurrent event repeats its action at a regular interval, and the schedule for a recurring event can be assigned a specific start day and time, end day and time, both, or neither. (By default, a recurring event's schedule begins as soon as it is created, and continues indefinitely, until it is disabled or dropped.)
- Users can create, modify, and drop scheduled events using SQL statements intended for these purposes. Syntactically invalid event creation and modification statements fail with an appropriate error message. *A user may include statements in an event's action which require privileges that the user does not actually have.* The event creation or modification statement succeeds but the event's action fails. See [Section 21.5, “The Event Scheduler and MySQL Privileges”](#) for details.
- Many of the properties of an event can be set or modified using SQL statements. These properties include the event's name, timing, persistence (that is, whether it is preserved following the expiration of its schedule), status (enabled or disabled), action to be performed, and the schema to which it is assigned. See [Section 21.2.1, “ALTER EVENT Syntax”](#).

The definer of an event is the user who created the event, unless the event has been altered, in which case the definer is the user who issued the last [ALTER EVENT](#) statement effecting that event. An event can be modified by any user having the [EVENT](#) privilege on

the database for which the event is defined. (Prior to MySQL 5.1.12, only an event's definer, or a user having privileges on the `mysql.event` table, could modify a given event.) See [Section 21.5, “The Event Scheduler and MySQL Privileges”](#).

- An event's action statement may include most SQL statements permitted within stored routines.

Events are executed by a special *event scheduler thread*; when we refer to the Event Scheduler, we actually refer to this thread. When running, the event scheduler thread and its current state can be seen by users having the `SUPER` privilege in the output of `SHOW PROCESSLIST`, as shown in the discussion that follows.

The global variable `event_scheduler` determines whether the Event Scheduler is enabled and running on the server. Beginning with MySQL 5.1.12, it has one of these 3 values, which affect event scheduling as described here:

- **OFF**: The Event Scheduler is stopped. The event scheduler thread does not run, is not shown in the output of `SHOW PROCESSLIST`, and no scheduled events are executed. **OFF** is the default value for `event_scheduler`.

When the Event Scheduler is stopped (`event_scheduler` is **OFF**), it can be started by setting the value of `event_scheduler` to **ON**. (See next item.)

- **ON**: The Event Scheduler is started; the event scheduler thread runs and executes all scheduled events.

When the Event Scheduler is **ON**, the event scheduler thread is listed in the output of `SHOW PROCESSLIST` as a daemon process, and its state is represented as shown here:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
  Id: 1
  User: root
  Host: localhost
  db: NULL
  Command: Query
  Time: 0
  State: NULL
  Info: show processlist
***** 2. row *****
  Id: 2
  User: event_scheduler
  Host: localhost
  db: NULL
  Command: Daemon
  Time: 3
  State: Waiting for next activation
  Info: NULL
2 rows in set (0.00 sec)
```

Event scheduling can be stopped by setting the value of `event_scheduler` to **OFF**.

- **DISABLED**: This value renders the Event Scheduler non-operational. When the Event Scheduler is **DISABLED**, the event scheduler thread does not run (and so does not appear in the output of `SHOW PROCESSLIST`).

When the server is running `event_scheduler` can be toggled between **ON** and **OFF** (using `SET`). It is also possible to use `0` for **OFF**, and `1` for **ON** when setting this variable. Thus, any of the following 4 statements can be used in the `mysql` client to turn on the Event Scheduler:

```
SET GLOBAL event_scheduler = ON;
SET @@global.event_scheduler = ON;
SET GLOBAL event_scheduler = 1;
SET @@global.event_scheduler = 1;
```

Similarly, any of these 4 statements can be used to turn off the Event Scheduler:

```
SET GLOBAL event_scheduler = OFF;
SET @@global.event_scheduler = OFF;
SET GLOBAL event_scheduler = 0;
SET @@global.event_scheduler = 0;
```

Although **ON** and **OFF** have numeric equivalents, the value displayed for `event_scheduler` by `SELECT` or `SHOW VARIABLES` is always one of **OFF**, **ON**, or **DISABLED**. **DISABLED** has no numeric equivalent. For this reason, **ON** and **OFF** are usually preferred over `1` and `0` when setting this variable.

Note that attempting to set `event_scheduler` without specifying it as a global variable causes an error:

```
mysql> SET @@event_scheduler = OFF;
ERROR 1229 (HY000): VARIABLE 'EVENT_SCHEDULER' IS A GLOBAL
VARIABLE AND SHOULD BE SET WITH SET GLOBAL
```

Important

It is not possible to enable or disable the Event Scheduler when the server is running. That is, you can change the value of `event_scheduler` to `DISABLED` — or from `DISABLED` to one of the other permitted values for this option — only when the server is stopped. Attempting to do so when the server is running fails with an error.

To disable the event scheduler, use one of the following two methods:

- As a command-line option when starting the server:

```
--event-scheduler=DISABLED
```

- In the server configuration file (`my.cnf`, or `my.ini` on Windows systems), include the line where it will be read by the server (for example, in a `[mysqld]` section):

```
event_scheduler=DISABLED
```

To enable the Event Scheduler, restart the server without the `--event-scheduler=DISABLED` command line option, or after removing or commenting out the line containing `event_scheduler=DISABLED` in the server configuration file, as appropriate. Alternatively, you can use `ON` (or `1`) or `OFF` (or `0`) in place of the `DISABLED` value when starting the server.

Note

You can issue event-manipulation statements when `event_scheduler` is set to `DISABLED`. No warnings or errors are generated in such cases (provided that the statements are themselves valid). However, scheduled events cannot execute until this variable is set to `ON` (or `1`). Once this has been done, the event scheduler thread executes all events whose scheduling conditions are satisfied.

In MySQL 5.1.11, `event_scheduler` behaved as follows: this variable could take one of the values `0` (or `OFF`), `1` (or `ON`), or `2`. Setting it to `0` turned event scheduling off, so that the event scheduler thread did not run; the `event_scheduler` variable could not be set to this value while the server was running. Setting it to `1` so that the event scheduler thread ran and executed scheduled events. In this state, the event scheduler thread appeared to be sleeping when viewed with `SHOW PROCESSLIST`. When `event_scheduler` was set to `2` (which was the default value), the Event Scheduler was considered to be “suspended”; the event scheduler thread ran and could be seen in the output of `SHOW PROCESSLIST` (where `Suspended` was displayed in the `State` column), but did not execute any scheduled events. The value of `event_scheduler` could be changed only between `1` (or `ON`) and `2` while the server was running. Setting it to `0` (or `OFF`) required a server restart, as did changing its value from `0` (or `OFF`) to `1` (or `ON`) or `2`.

Prior to MySQL 5.1.11, `event_scheduler` could take one of only the 2 values `0|OFF` or `1|ON`, and the default value was `0|OFF`. It was also possible to start and stop the event scheduler thread while the MySQL server was running.

For more information concerning the reasons for these changes in behaviour, see [Bug#17619](#).

Beginning with MySQL 5.1.17, starting the MySQL server with the `--skip-grant-tables` option causes `event_scheduler` to be set to `DISABLED`, overriding any other value set either on the command line or in the `my.cnf` or `my.ini` file ([Bug#26807](#)).

For SQL statements used to create, alter, and drop events, see [Section 21.2, “Event Scheduler Syntax”](#).

MySQL 5.1.6 and later provides an `EVENTS` table in the `INFORMATION_SCHEMA` database. This table can be queried to obtain information about scheduled events which have been defined on the server. See [Section 21.3, “Event Metadata”](#), and [Section 23.20, “The INFORMATION_SCHEMA EVENTS Table”](#), for more information.

For information regarding event scheduling and the MySQL privilege system, see [Section 21.5, “The Event Scheduler and MySQL Privileges”](#).

21.2. Event Scheduler Syntax

MySQL 5.1.6 and later provides several SQL statements for working with scheduled events:

- New events are defined using the `CREATE EVENT` statement. See [Section 21.2.2, “CREATE EVENT Syntax”](#).
- The definition of an existing event can be changed by means of the `ALTER EVENT` statement. See [Section 21.2.1, “ALTER EVENT Syntax”](#).
- When a scheduled event is no longer wanted or needed, it can be deleted from the server by its definer using the `DROP EVENT` statement. See [Section 21.2.3, “DROP EVENT Syntax”](#). (Whether an event persists past the end of its schedule also depends on its `ON COMPLETION` clause, if it has one. See [Section 21.2.2, “CREATE EVENT Syntax”](#).)

An event can be deleted by any user having the `EVENT` privilege for the database on which the event is defined. Prior to MySQL 5.1.2, a user other than the definer required privileges on the `mysql.event` table. See [Section 21.5, “The Event Scheduler and MySQL Privileges”](#).

21.2.1. ALTER EVENT Syntax

```
ALTER EVENT
[DEFINER = { user | CURRENT_USER }]
event_name
[ON SCHEDULE schedule]
[RENAME TO new_event_name]
[ON COMPLETION [NOT] PRESERVE]
[ENABLE | DISABLE] [DISABLE ON SLAVE]
[COMMENT 'comment']
[DO sql_statement]
```

The `ALTER EVENT` statement is used to change one or more of the characteristics of an existing event without the need to drop and re-create it. The syntax for each of the `DEFINER`, `ON SCHEDULE`, `ON COMPLETION`, `COMMENT`, `ENABLE / DISABLE`, and `DO` clauses is exactly the same as when used with `CREATE EVENT`. (See [Section 21.2.2, “CREATE EVENT Syntax”](#).)

Support for the `DEFINER` clause was added in MySQL 5.1.17.

Beginning with MySQL 5.1.12, any user can alter an event defined on a database for which that user has the `EVENT` privilege. When a user executes a successful `ALTER EVENT` statement, that user becomes the definer for the affected event.

(In MySQL 5.1.11 and earlier, an event could be altered only by its definer, or by a user having the `SUPER` privilege.)

`ALTER EVENT` works only with an existing event:

```
mysql> ALTER EVENT no_such_event
> ON SCHEDULE
> EVERY '2:3' DAY_HOUR;
ERROR 1517 (HY000): UNKNOWN EVENT 'NO_SUCH_EVENT'
```

In each of the following examples, assume that the event named `myevent` is defined as shown here:

```
CREATE EVENT myevent
ON SCHEDULE
EVERY 6 HOUR
COMMENT 'A sample comment.'
DO
UPDATE myschema.mytable SET mycol = mycol + 1;
```

The following statement changes the schedule for `myevent` from once every six hours starting immediately to once every twelve hours, starting four hours from the time the statement is run:

```
ALTER EVENT myevent
ON SCHEDULE
EVERY 12 HOUR
STARTS CURRENT_TIMESTAMP + 4 HOUR;
```

To disable `myevent`, use this `ALTER EVENT` statement:

```
ALTER EVENT myevent
DISABLE;
```

The **ON SCHEDULE** clause may use expressions involving built-in MySQL functions and user variables to obtain any of the *timestamp* or *interval* values which it contains. You may not use stored routines or user-defined functions in such expressions, nor may you use any table references; however, you may use **SELECT FROM DUAL**. This is true for both **ALTER EVENT** and **CREATE EVENT** statements. Beginning with MySQL 5.1.13, references to stored routines, user-defined functions, and tables in such cases are specifically disallowed, and fail with an error (see [Bug#22830](#)).

An **ALTER EVENT** statement that contains another **ALTER EVENT** statement in its **DO** clause appears to succeed; however, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

It is possible to change multiple characteristics of an event in a single statement. This example changes the SQL statement executed by *myevent* to one that deletes all records from *mytable*; it also changes the schedule for the event such that it executes once, one day after this **ALTER EVENT** statement is run.

```
ALTER TABLE myevent
ON SCHEDULE
  AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
DO
  TRUNCATE TABLE myschema.mytable;
```

To rename an event, use the **ALTER EVENT** statement's **RENAME TO** clause, as shown here:

```
ALTER EVENT myevent
RENAME TO yourevent;
```

The previous statement renames the event *myevent* to *yourevent*.

Note

There is no **RENAME EVENT** statement.

You can also move an event to a different database using **ALTER EVENT ... RENAME TO ...** and *db_name.table_name* notation, as shown here:

```
ALTER EVENT olddb.myevent
RENAME TO newdb.myevent;
```

In order to execute the previous statement, the user executing it must have the **EVENT** privilege on both the *olddb* and *newdb* databases.

Beginning with MySQL 5.1.18, a third value may also appear in place of **ENABLED** or **DISABLED**; **DISABLE ON SLAVE** is used on a replication slave to indicate an event which was created on the master and replicated to the slave, but which is not executed on the slave. Normally, **DISABLE ON SLAVE** is set automatically as required; however, there are some circumstances under which you may want or need to change it manually. See [Section 15.3.1.5, “Replication of Invoked Features”](#), for more information.

It is necessary to include only those options in an **ALTER EVENT** statement which correspond to characteristics that you actually wish to change; options which are omitted retain their existing values. This includes any default values for **CREATE EVENT** such as **ENABLE**.

21.2.2. CREATE EVENT Syntax

```
CREATE
  [DEFINER = { user | CURRENT_USER }]
  EVENT
  [IF NOT EXISTS]
  event_name
  ON SCHEDULE schedule
  [ON COMPLETION [NOT] PRESERVE]
  [ENABLE | DISABLE | DISABLE ON SLAVE]
  [COMMENT 'comment']
  DO sql_statement;

schedule:
  AT timestamp [+ INTERVAL interval]
  | EVERY interval
  [STARTS timestamp [+ INTERVAL interval]]
  [ENDS timestamp [+ INTERVAL interval]]

interval:
  quantity {YEAR | QUARTER | MONTH | DAY | HOUR | MINUTE |
             WEEK | SECOND | YEAR_MONTH | DAY_HOUR | DAY_MINUTE |
             DAY_SECOND | HOUR_MINUTE | HOUR_SECOND | MINUTE_SECOND}
```

This statement creates and schedules a new event. The minimum requirements for a valid **CREATE EVENT** statement are as follows:

- The keywords **CREATE EVENT** plus an event name, which uniquely identifies the event in the current schema.
(Prior to MySQL 5.1.12, the event name needed to be unique only among events created by the same user on a given database.)
- An **ON SCHEDULE** clause, which determines when and how often the event executes.
- A **DO** clause, which contains the SQL statement to be executed by an event.

This is an example of a minimal **CREATE EVENT** statement:

```
CREATE EVENT myevent
  ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
  DO
    UPDATE myschema.mytable SET mycol = mycol + 1;
```

The previous statement creates an event named **myevent**. This event executes once — one hour following its creation — by running an SQL statement that increments the value of the **myschema.mytable** table's **mycol** column by 1.

The *event_name* must be a valid MySQL identifier with a maximum length of 64 characters. It may be delimited using back ticks, and may be qualified with the name of a database schema. An event is associated with both a MySQL user (the definer) and a schema, and its name must be unique among names of events within that schema. In general, the rules governing event names are the same as those for names of stored routines. See [Section 8.2, “Identifiers”](#).

If no schema is indicated as part of *event_name*, then the default (current) schema is assumed. The definer is always the current MySQL user.

(Prior to MySQL 5.1.12, it was possible for two different users to create different events having the same name on the same database schema.)

Note

MySQL uses case-insensitive comparisons when checking for the uniqueness of event names. This means that, for example, you cannot have two events named **myevent** and **MyEvent** in the same database schema.

The **DEFINER** clause specifies the MySQL account to be used when checking access privileges at trigger execution time. If a *user* value is given, it should be a MySQL account in '*user_name*'@'*host_name*' format (the same format used in the **GRANT** statement). The *user_name* and *host_name* values both are required. **CURRENT_USER** also can be given as **CURRENT_USER()**. The default **DEFINER** value is the user who executes the **CREATE TRIGGER** statement. (This is the same as **DEFINER = CURRENT_USER**.)

The **DEFINER** clause was added in MySQL 5.1.17.

IF NOT EXISTS functions in the same fashion with **CREATE EVENT** as it does when used with a **CREATE TABLE** statement; if an event named *event_name* already exists in the same schema, no action is taken, and no error results. (However, a warning is generated in such cases.)

The **ON SCHEDULE** clause determines when, how often, and for how long the *sql_statement* defined for the event repeats. This clause takes one of two forms:

- **AT timestamp** is used for a one-time event. It specifies that the event executes one time only at the date and time, given as the *timestamp*, which must include both the date and time, or must be an expression that resolves to a datetime value. You may use a value which is of either the **DATETIME** or **TIMESTAMP** type for this purpose. The *timestamp* must also be in the future — you cannot schedule an event to take place in the past. Trying to do so fails with an error, as shown here:

```
mysql> SELECT NOW();
+-----+
| NOW() |
+-----+
| 2006-02-10 23:59:01 |
+-----+
1 row in set (0.04 sec)

mysql> CREATE EVENT e_totals
```

```
-> ON SCHEDULE AT '2006-02-10 23:59:00'  
-> DO INSERT INTO test.totals VALUES (NOW());  
ERROR 1522 (HY000): ACTIVATION (AT) TIME IS IN THE PAST
```

CREATE EVENT statements which are themselves invalid — for whatever reason — fail with an error.

You may use **CURRENT_TIMESTAMP** to specify the current date and time. In such a case, the event acts as soon as it is created.

In order to create an event which occurs at some point in the future relative to the current date and time — such as that expressed by the phrase “three weeks from now” — you can use the optional clause **+ INTERVAL interval**. The *interval* portion consists of two parts, a quantity and a unit of time, and follows the same syntax rules that govern intervals used in the **DATE_ADD()** function (see [Section 11.6, “Date and Time Functions”](#)). The units keywords are also the same, except that you cannot use any units involving microseconds when defining an event.

You can also combine intervals. For example, **AT CURRENT_TIMESTAMP + INTERVAL 3 WEEK + INTERVAL 2 DAY** is equivalent to “three weeks and two days from now”. Each portion of such a clause must begin with **+ INTERVAL**.

- For actions which are to be repeated at a regular interval, you can use an **EVERY** clause. The **EVERY** keyword is followed by an *interval* as described in the previous discussion of the **AT** keyword. (**+ INTERVAL** is *not* used with **EVERY**.) For example, **EVERY 6 WEEK** means “every six weeks”.

It is not possible to combine **+ INTERVAL** clauses in a single **EVERY** clause; however, you can use the same complex time units allowed in a **+ INTERVAL**. For example, “every two minutes and ten seconds” can be expressed as **EVERY '2:10' MINUTE_SECOND**.

An **EVERY** clause may also contain an optional **STARTS** clause. **STARTS** is followed by a *timestamp* value which indicates when the action should begin repeating, and may also use **+ INTERVAL interval** in order to specify an amount of time “from now”. For example, **EVERY 3 MONTH STARTS CURRENT_TIMESTAMP + 1 WEEK** means “every three months, beginning one week from now”. Similarly, you can express “every two weeks, beginning six hours and fifteen minutes from now” as **EVERY 2 WEEK STARTS CURRENT_TIMESTAMP + INTERVAL '6:15' HOUR_MINUTE**. Not specifying **STARTS** is the same as using **STARTS CURRENT_TIMESTAMP** — that is, the action specified for the event begins repeating immediately upon creation of the event.

An **EVERY** clause may also contain an optional **ENDS** clause. The **ENDS** keyword is followed by a *timestamp* value which tells MySQL when the event should stop repeating. You may also use **+ INTERVAL interval** with **ENDS**; for instance, **EVERY 12 HOUR STARTS CURRENT_TIMESTAMP + INTERVAL 30 MINUTE ENDS CURRENT_TIMESTAMP + INTERVAL 4 WEEK** is equivalent to “every twelve hours, beginning thirty minutes from now, and ending four weeks from now”. Not using **ENDS** means that the event continues executing indefinitely.

ENDS supports the same syntax for complex time units as **STARTS** does.

You may use **STARTS**, **ENDS**, both, or neither in an **EVERY** clause.

Note

Beginning with MySQL 5.1.17, **STARTS** or **ENDS** uses the MySQL server's local time zone, as shown in the **INFORMATION_SCHEMA.EVENTS** and **mysql.event** tables, as well as in the output of **SHOW EVENTS**. Previously, this information was stored using UTC ([Bug#16420](#)).

Due to this change, the **mysql.event** table must be updated before events created in earlier releases can be created, altered, viewed, or used in MySQL 5.1.17 or later.

See [Section 23.20, “The INFORMATION_SCHEMA EVENTS Table”](#), and [Section 12.5.4.16, “SHOW EVENTS”](#) for information about columns added in MySQL 5.1.17 to accommodate these changes.

The **ON SCHEDULE** clause may use expressions involving built-in MySQL functions and user variables to obtain any of the *timestamp* or *interval* values which it contains. You may not use stored routines or user-defined functions in such expressions, nor may you use any table references; however, you may use **SELECT FROM DUAL**. This is true for both **CREATE EVENT** and **ALTER EVENT** statements. Beginning with MySQL 5.1.13, references to stored routines, user-defined functions, and tables in such cases are specifically disallowed, and fail with an error (see [Bug#22830](#)).

Normally, once an event has expired, it is immediately dropped. You can override this behavior by specifying **ON COMPLETION PRESERVE**. Using **ON COMPLETION NOT PRESERVE** merely makes the default non-persistent behavior explicit.

You can create an event but keep it from being active using the `DISABLE` keyword. Alternatively, you may use `ENABLE` to make explicit the default status, which is active. This is most useful in conjunction with `ALTER EVENT` (see [Section 21.2.1, “ALTER EVENT Syntax”](#)).

Beginning with MySQL 5.1.18, a third value may also appear in place of `ENABLED` or `DISABLED`; `DISABLE ON SLAVE` is set for the status of an event on a replication slave to indicate that the event was created on the master and replicated to the slave, but is not executed on the slave. See [Section 15.3.1.5, “Replication of Invoked Features”](#).

You may supply a comment for an event using a `COMMENT` clause. *comment* may be any string of up to 64 characters that you wish to use for describing the event. The comment text, being a string literal, must be surrounded by quotation marks.

The `DO` clause specifies an action carried by the event, and consists of an SQL statement. Nearly any valid MySQL statement which can be used in a stored routine can also be used as the action statement for a scheduled event. (See [Section D.1, “Restrictions on Stored Routines and Triggers”](#).) For example, the following event `e_hourly` deletes all rows from the `sessions` table once per hour, where this table is part of the `site_activity` schema:

```
CREATE EVENT e_hourly
ON SCHEDULE
  EVERY 1 HOUR
COMMENT 'Clears out sessions table each hour.'
DO
  DELETE FROM site_activity.sessions;
```

MySQL stores the `sql_mode` system variable setting that is in effect at the time an event is created, and always executes the event with this setting in force, *regardless of the current server SQL mode*.

A `CREATE EVENT` statement that contains an `ALTER EVENT` statement in its `DO` clause appears to succeed; however, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

Note

The `SHOW` statement and `SELECT` statements that merely return a result set have no effect when used in an event; the output from these is not sent to the MySQL Monitor, nor is it stored anywhere. However, you can use statements such as `SELECT INTO` and `INSERT ... SELECT` that store a result. (See the next example in this section for an instance of the latter.)

Any reference in the `DO` clause to a table in other than the same database schema to which the event belongs must be qualified with the name of the schema in which the table occurs. (In MySQL 5.1.6, all tables referenced in event `DO` clauses had to include a reference to the database.)

As with stored routines, you can use multiple statements in the `DO` clause by bracketing them with the `BEGIN` and `END` keywords, as shown here:

```
DELIMITER |
CREATE EVENT e_daily
ON SCHEDULE
  EVERY 1 DAY
COMMENT 'Saves total number of sessions then clears the table each day.'
DO
  BEGIN
    INSERT INTO site_activity.totals (when, total)
      SELECT CURRENT_TIMESTAMP, COUNT(*)
        FROM site_activity.sessions;
    DELETE FROM site_activity.sessions;
  END |
DELIMITER ;
```

Note the use of the `DELIMITER` statement to change the statement delimiter, as with stored routines. See [Section 19.2.1, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#).

More complex compound statements, such as those used in stored routines, are possible in an event. This example uses local variables, an error handler, and a flow control construct:

```
DELIMITER |
CREATE EVENT e
ON SCHEDULE
  EVERY 5 SECOND
DO
  BEGIN
```

```
DECLARE v INTEGER;
DECLARE CONTINUE HANDLER FOR SQLEXCEPTION BEGIN END;

SET v = 0;

WHILE v < 5 DO
    INSERT INTO t1 VALUES (0);
    UPDATE t2 SET s1 = s1 + 1;
    SET v = v + 1;
END WHILE;
END |
DELIMITER ;
```

There is no way to pass parameters directly to or from events; however, it is possible to invoke a stored routine with parameters:

```
CREATE EVENT e_call_myproc
ON SCHEDULE
AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
DO CALL myproc(5, 27);
```

In addition, if the event's definer has the [SUPER](#) privilege, that event may read and write global variables. As granting this privilege entails a potential for abuse, extreme care must be taken in doing so.

Generally, any statements which are valid in stored routines may be used for action statements executed by events. For more information about statements allowable within stored routines, see [Section 19.2, “Stored Routine Syntax”](#). You can create an event as part of a stored routine, but an event cannot be created by another event.

21.2.3. DROP EVENT Syntax

```
DROP EVENT [IF EXISTS] event_name
```

This statement drops the event named *event_name*. The event immediately ceases being active, and is deleted completely from the server.

If the event does not exist, the error **ERROR 1517 (HY000): UNKNOWN EVENT 'EVENT_NAME'** results. You can override this and cause the statement to fail silently by using **IF EXISTS**.

Beginning with MySQL 5.1.12, an event can be dropped by any user having the [EVENT](#) privilege on the database schema to which the event to be dropped belongs. (In MySQL 5.1.11 and earlier, an event could be dropped only by its definer, or by a user having the [SUPER](#) privilege.)

21.3. Event Metadata

Information about events can be obtained as follows:

- Querying the [EVENTS](#) table of the [INFORMATION_SCHEMA](#) database. See [Section 23.20, “The INFORMATION_SCHEMA EVENTS Table”](#).
- Using the [SHOW EVENTS](#) statement. See [Section 12.5.4.16, “SHOW EVENTS”](#).
- Using the [SHOW CREATE EVENT](#) statement. See [Section 12.5.4.7, “SHOW CREATE EVENT”](#).
- A record of events executed on the server can be read from the MySQL Server's error log (see [Section 21.5, “The Event Scheduler and MySQL Privileges”](#) for an example).

21.4. Event Scheduler Status

Information about the state of the Event Scheduler for debugging and troubleshooting purposes can be obtained as follows:

- In MySQL 5.1.11 **-debug** builds, you can use the [SHOW SCHEDULER STATUS](#) statement; see [Section 12.5.4.26, “SHOW SCHEDULER STATUS Syntax”](#).

Important

This statement was removed in MySQL 5.1.12. We intend to implement an SQL statement providing similar functionality in a future MySQL release.

- Beginning with MySQL 5.1.12, event scheduler status information can be obtained by running `mysqladmin debug` (see [Section 7.10, “mysqladmin — Client for Administering a MySQL Server”](#)); after running this command, the error log contains output relating to the Event Scheduler, similar to what is shown here:

```
Events status:
LLA = Last Locked At   LUA = Last Unlocked At
WOC = Waiting On Condition  DL = Data Locked

Event scheduler status:
State      : INITIALIZED
Thread id  : 0
LLA        : init_scheduler:313
LUA        : init_scheduler:318
WOC        : NO
Workers    : 0
Executed   : 0
Data locked: NO

Event queue status:
Element count : 1
Data locked   : NO
Attempting lock : NO
LLA          : init_queue:148
LUA          : init_queue:168
WOC          : NO
Next activation : 0000-00-00 00:00:00
```

21.5. The Event Scheduler and MySQL Privileges

To enable or disable the execution of scheduled events, it is necessary to set the value of the global `event_scheduler` variable. This requires the `SUPER` privilege.

MySQL 5.1.6 introduces a privilege governing the creation, modification, and deletion of events, the `EVENT` privilege. This privilege can be bestowed using `GRANT`. For example, this `GRANT` statement confers the `EVENT` privilege for the schema named `myschema` on the user `jon@ghidora`:

```
GRANT EVENT ON myschema.* TO jon@ghidora;
```

(We assume that this user account already exists, and that we wish for it to remain unchanged otherwise.)

To grant this same user the `EVENT` privilege on all schemas would require the following statement:

```
GRANT EVENT ON *.* TO jon@ghidora;
```

The `EVENT` privilege has schema-level scope. Therefore, trying to grant it on a single table results in an error as shown:

```
mysql> GRANT EVENT ON myschema.mytable TO jon@ghidora;
ERROR 1144 (42000): ILLEGAL GRANT/REVOKE COMMAND; PLEASE
CONSULT THE MANUAL TO SEE WHICH PRIVILEGES CAN BE USED
```

It is important to understand that an event is executed with the privileges of its definer, and that it cannot perform any actions for which its definer does not have the requisite privileges. For example, suppose that `jon@ghidora` has the `EVENT` privilege for `myschema`. Suppose also that this user has the `SELECT` privilege for `myschema`, but no other privileges for this schema. It is possible for `jon@ghidora` to create a new event such as this one:

```
CREATE EVENT e_store_ts
ON SCHEDULE
EVERY 10 SECOND
DO
INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
```

The user waits for a minute or so, and then performs a `SELECT * FROM mytable;` query, expecting to see several new rows in the table. Instead, he finds that the table is empty. Since he does not have the `INSERT` privilege for the table in question, the event has no

effect.

If you inspect the MySQL error log (*hostname.err*), you can see that the event is executing, but the action it is attempting to perform fails, as indicated by `RetCode=0`:

```
060209 22:39:44 [Note] EVEX EXECUTING event newdb.e [EXPR:10]
060209 22:39:44 [Note] EVEX EXECUTED event newdb.e [EXPR:10]. RetCode=0
060209 22:39:54 [Note] EVEX EXECUTING event newdb.e [EXPR:10]
060209 22:39:54 [Note] EVEX EXECUTED event newdb.e [EXPR:10]. RetCode=0
060209 22:40:04 [Note] EVEX EXECUTING event newdb.e [EXPR:10]
060209 22:40:04 [Note] EVEX EXECUTED event newdb.e [EXPR:10]. RetCode=0
```

Since this user very likely does not have access to the error log, he can verify whether the event's action statement is valid by running it himself:

```
mysql> INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
ERROR 1142 (42000): INSERT COMMAND DENIED TO USER
'JON'@'GHIDORA' FOR TABLE 'MYTABLE'
```

Inspection of the `INFORMATION_SCHEMA.EVENTS` table shows that `e_store_ts` exists and is enabled, but its `LAST_EXECUTED` column is `NULL`:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
> WHERE EVENT_NAME='e_store_ts'
> AND EVENT_SCHEMA='myschema'\G
***** 1. row *****
EVENT_CATALOG: NULL
EVENT_SCHEMA: myschema
EVENT_NAME: e_store_ts
DEFINER: jon@ghidora
EVENT_BODY: SQL
EVENT_DEFINITION: INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP())
EVENT_TYPE: RECURRING
EXECUTE_AT: NULL
INTERVAL_VALUE: 5
INTERVAL_FIELD: INTERVAL_SECOND
SQL_MODE: NULL
STARTS: 0000-00-00 00:00:00
ENDS: 0000-00-00 00:00:00
STATUS: ENABLED
ON_COMPLETION: NOT PRESERVE
CREATED: 2006-02-09 22:36:06
LAST_ALTERED: 2006-02-09 22:36:06
LAST_EXECUTED: NULL
EVENT_COMMENT:
1 row in set (0.00 sec)
```

Note

Prior to MySQL 5.1.12, there was no `EVENT_DEFINITION` column, and `EVENT_BODY` contained the SQL statement or statements to be executed. See [Section 23.20, “The INFORMATION_SCHEMA EVENTS Table”](#), for more information.

To rescind the `EVENT` privilege, use the `REVOKE` statement. In this example, the `EVENT` privilege on the schema `myschema` is removed from the `jon@ghidora` user account:

```
REVOKE EVENT ON myschema.* FROM jon@ghidora;
```

Important

Revoking the `EVENT` privilege from a user does not delete or disable any events that may have been created by that user.

An event is not migrated or dropped as a result of the renaming or dropping of the user who created it.

For example, suppose that that user `jon@ghidora` has been granted the `EVENT` and `INSERT` privileges on the `myschema` schema. This user then creates the following event:

```
CREATE EVENT e_insert
ON SCHEDULE
EVERY 7 SECOND
DO
INSERT INTO myschema.mytable;
```

After this event has been created, `root` revokes the `EVENT` privilege for `jon@ghidora`. However, `e_insert` continues to execute,

inserting a new row into `mytable` each seven seconds. The same would be true if `root` had issued either of these statements:

- `DROP USER jon@ghidora;`
- `RENAME USER jon@ghidora TO someotherguy@ghidora;`

You can verify that this is true by examining the `mysql.event` table (discussed later in this section) or the `INFORMATION_SCHEMA.EVENTS` table (see [Section 23.20, “The INFORMATION_SCHEMA EVENTS Table”](#)) before and after issuing a `DROP USER` or `RENAME USER` statement.

Event definitions are stored in the `mysql.event` table, which was added in MySQL 5.1.6. To drop an event created by another user account, the MySQL `root` user (or another user with the necessary privileges) can delete rows from this table. For example, to remove the event `e_insert` shown previously, `root` can use the following statement:

```
DELETE FROM mysql.event
WHERE db = 'myschema'
  AND definer = 'jon@ghidora'
  AND name = 'e_insert';
```

It is very important to match the event name, database schema name, and user account when deleting rows from the `mysql.event` table. This is because the same user can create different events of the same name in different schemas.

Note

The namespace for scheduled events changed in MySQL 5.1.12. Prior to that MySQL version, different users could create different events having the same name in the same database; in MySQL 5.1.12 and later, that is no longer the case. When upgrading to MySQL 5.1.12 or later from MySQL 5.1.11 or earlier, it is extremely important to make sure that no events in the same database share the same name, *prior to performing the upgrade*.

Users' `EVENT` privileges are stored in the `Event_priv` columns of the `mysql.user` and `mysql.db` tables. In both cases, this column holds one of the values 'Y' or 'N'. 'N' is the default. `mysql.user.Event_priv` is set to 'Y' for a given user only if that user has the global `EVENT` privilege (that is, if the privilege was bestowed using `GRANT EVENT ON *.*`). For a schema-level `EVENT` privilege, `GRANT` creates a row in `mysql.db` and sets that row's `Db` column to the name of the schema, the `User` column to the name of the user, and the `Event_priv` column to 'Y'. There should never be any need to manipulate these tables directly, since the `GRANT EVENT` and `REVOKE EVENT` statement perform the required operations on them.

MySQL 5.1.6 introduces five status variables providing counts of event-related operations (but *not* of statements executed by events — see [Section 21.6, “Event Scheduler Limitations and Restrictions”](#)). These are:

- `Com_create_event`: The number of `CREATE EVENT` statements executed since the last server restart.
- `Com_alter_event`: The number of `ALTER EVENT` statements executed since the last server restart.
- `Com_drop_event`: The number of `DROP EVENT` statements executed since the last server restart.
- `Com_show_create_event`: The number of `SHOW CREATE EVENT` statements executed since the last server restart.
- `Com_show_events`: The number of `SHOW EVENTS` statements executed since the last server restart.

You can view current values for all of these at one time by running the statement `SHOW STATUS LIKE '%event%';`.

21.6. Event Scheduler Limitations and Restrictions

This section lists restrictions and limitations applying to event scheduling in MySQL 5.1.

Qualification of identifiers. In MySQL 5.1.6 only, any table referenced in an event's action statement must be fully qualified with the name of the schema in which it occurs (that is, as `schema_name.table_name`).

Case sensitivity of event identifiers. Beginning with MySQL 5.1.8, event names are handled in case-insensitive fashion. For example, this means that you cannot have two events in the same database (and — prior to MySQL 5.1.12 — with the same definer) with the names `anEvent` and `AnEvent`.

Important

If you have events created in MySQL 5.1.7 or earlier which are assigned to the same database and have the same definer, and whose names differ only with respect to lettercase, then you must rename these events to respect case-sensitive handling before upgrading to MySQL 5.1.8 or later.

Modification of events by stored routines and triggers. An event may not be created, altered, or dropped by a trigger, stored routine, or another event. An event also may not create, alter, or drop triggers or stored routines. ([Bug#16409](#), [Bug#18896](#))

Resolution of event timings. Event timings using the intervals [YEAR](#), [QUARTER](#), [MONTH](#), and [YEAR_MONTH](#) are resolved in months; those using any other interval are resolved in seconds. There is no way to cause events scheduled to occur at the same second to execute in a given order. In addition — due to rounding, the nature of threaded applications, and the fact that a non-zero length of time is required to create events and to signal their execution — events may be delayed by as much as 1 or 2 seconds. However, the time shown in the [INFORMATION_SCHEMA.EVENTS](#) table's [LAST_EXECUTED](#) column or the [mysql.event](#) table's [last_executed](#) column is always accurate to within one second of the time the event was actually executed. (See also [Bug#16522](#).)

Effects on statement counts. Each execution of the statements contained in the body of an event takes place in a new connection; thus, these statements has no effect in a given user session on the server's statement counts such as [Com_select](#) and [Com_insert](#) that are displayed by [SHOW STATUS](#). However, such counts are updated in the global scope. ([Bug#16422](#))

Visibility of events belonging to other users. Prior to MySQL 5.1.12, you could not view another user's events in the [INFORMATION_SCHEMA.EVENTS](#) table. In other words, any query made against this table was treated as though it contained the condition [DEFINER = CURRENT_USER\(\)](#) in the [WHERE](#) clause.

Start times. Events cannot be created with a start time that is in the past.

Latest time supported. Events do not support times later than the end of the Unix Epoch; this is approximately the end of the year 2038. Prior to MySQL 5.1.8, handling in scheduled events of dates later than this was buggy; starting with MySQL 5.1.8, such dates are specifically disallowed by the Event Scheduler. ([Bug#16396](#))

Server SQL mode. In MySQL 5.1.6, [INFORMATION_SCHEMA.EVENTS](#) shows [NULL](#) in the [SQL_MODE](#) column. Beginning with MySQL 5.1.7, the [SQL_MODE](#) displayed is that in effect when the event was created.

Dropping or altering events. In MySQL 5.1.6, the only way to drop or alter an event created by a user who was not the definer of that event was by manipulation of the [mysql.event](#) system table by the MySQL [root](#) user or by another user with privileges on this table. Beginning with MySQL 5.1.7, [DROP USER](#) drops all events for which that user was the definer; also beginning with MySQL 5.1.7 [DROP SCHEMA](#) drops all events associated with the dropped schema.

Schema migration not supported. As with stored routines, events are not migrated to the new schema by the [RENAME SCHEMA](#) (or [RENAME DATABASE](#)) statement. See [Section 12.1.18, “RENAME DATABASE Syntax”](#).

Database object references in ON SCHEDULE clauses. References to stored routines, user-defined functions, and tables in the [ON SCHEDULE](#) clauses of [CREATE EVENT](#) and [ALTER EVENT](#) statements are not supported. Beginning with MySQL 5.1.13, these sorts of references are disallowed. (See [Bug#22830](#) for more information.)

Disallowed statements. Generally speaking, statements which are not permitted in stored routines or in SQL prepared statements are also not allowed in the body of an event. See [Section D.1, “Restrictions on Stored Routines and Triggers”](#), and [Section 12.7, “SQL Syntax for Prepared Statements”](#), for more information.

Upgrading to MySQL 5.1.18 or later. When upgrading to MySQL 5.1.18 or later from a previous MySQL version where scheduled events were in use, the upgrade utilities [mysql_upgrade](#) and [mysql_fix_privilege_tables](#) do not accomodate changes in system tables relating to the Event Scheduler. As a workaround, you can dump events before the upgrade, then restore them from the dump afterwards. This issue was fixed in MySQL 5.1.20 (see [Bug#28521](#)).

Chapter 22. Views

Views (including updatable views) are available in MySQL Server 5.1.

Answers to some frequently asked questions concerning views in MySQL 5.1 can be found in [Section A.6, “MySQL 5.1 FAQ — Views”](#).

This chapter discusses the following topics:

- Creating or altering views with [CREATE VIEW](#) or [ALTER VIEW](#)
- Destroying views with [DROP VIEW](#)

Discussion of restrictions on use of views is given in [Section D.4, “Restrictions on Views”](#).

To use views if you have upgraded to MySQL 5.1 from an older release that did not support views, you should upgrade your grant tables so that they contain the view-related privileges. See [Section 5.5.7, “mysql_upgrade — Check Tables for MySQL Upgrade”](#).

Metadata about views can be obtained from the [INFORMATION_SCHEMA.VIEWS](#) table and by using the [SHOW CREATE VIEW](#) statement. See [Section 23.15, “The INFORMATION_SCHEMA VIEWS Table”](#), and [Section 12.5.4.11, “SHOW CREATE VIEW Syntax”](#).

22.1. ALTER VIEW Syntax

```
ALTER
[ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
[DEFINER = { user | CURRENT_USER }]
[SQL SECURITY { DEFINER | INVOKER }]
VIEW view_name [(column_list)]
AS select_statement
[WITH [CASCADED | LOCAL] CHECK OPTION]
```

This statement changes the definition of a view, which must exist. The syntax is similar to that for [CREATE VIEW](#) and the effect is the same as for [CREATE OR REPLACE VIEW](#). See [Section 22.2, “CREATE VIEW Syntax”](#). This statement requires the [CREATE VIEW](#) and [DROP](#) privileges for the view, and some privilege for each column referred to in the [SELECT](#) statement.

22.2. CREATE VIEW Syntax

```
CREATE
[OR REPLACE]
[ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
[DEFINER = { user | CURRENT_USER }]
[SQL SECURITY { DEFINER | INVOKER }]
VIEW view_name [(column_list)]
AS select_statement
[WITH [CASCADED | LOCAL] CHECK OPTION]
```

This statement creates a new view, or replaces an existing one if the [OR REPLACE](#) clause is given. If the view does not exist, [CREATE OR REPLACE VIEW](#) is the same as [CREATE VIEW](#). If the view does exist, [CREATE OR REPLACE VIEW](#) is the same as [ALTER VIEW](#). The *select_statement* is a [SELECT](#) statement that provides the definition of the view. The statement can select from base tables or other views.

This statement requires the [CREATE VIEW](#) privilege for the view, and some privilege for each column selected by the [SELECT](#) statement. For columns used elsewhere in the [SELECT](#) statement you must have the [SELECT](#) privilege. If the [OR REPLACE](#) clause is present, you must also have the [DROP](#) privilege for the view.

A view belongs to a database. By default, a new view is created in the default database. To create the view explicitly in a given database, specify the name as *db_name.view_name* when you create it.

```
mysql> CREATE VIEW test.v AS SELECT * FROM t;
```

Base tables and views share the same namespace within a database, so a database cannot contain a base table and a view that have the same name.

Views must have unique column names with no duplicates, just like base tables. By default, the names of the columns retrieved by the `SELECT` statement are used for the view column names. To define explicit names for the view columns, the optional `column_list` clause can be given as a list of comma-separated identifiers. The number of names in `column_list` must be the same as the number of columns retrieved by the `SELECT` statement.

Columns retrieved by the `SELECT` statement can be simple references to table columns. They can also be expressions that use functions, constant values, operators, and so forth.

Unqualified table or view names in the `SELECT` statement are interpreted with respect to the default database. A view can refer to tables or views in other databases by qualifying the table or view name with the proper database name.

A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables. The following example defines a view that selects two columns from another table, as well as an expression calculated from those columns:

```
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+-----+-----+-----+
| qty | price | value |
+-----+-----+-----+
| 3   | 50    | 150   |
+-----+-----+-----+
```

A view definition is subject to the following restrictions:

- The `SELECT` statement cannot contain a subquery in the `FROM` clause.
- The `SELECT` statement cannot refer to system or user variables.
- The `SELECT` statement cannot refer to prepared statement parameters.
- Within a stored routine, the definition cannot refer to routine parameters or local variables.
- Any table or view referred to in the definition must exist. However, after a view has been created, it is possible to drop a table or view that the definition refers to. In this case, use of the view results in an error. To check a view definition for problems of this kind, use the `CHECK TABLE` statement.
- The definition cannot refer to a `TEMPORARY` table, and you cannot create a `TEMPORARY` view.
- The tables named in the view definition must already exist.
- You cannot associate a trigger with a view.

`ORDER BY` is allowed in a view definition, but it is ignored if you select from a view using a statement that has its own `ORDER BY`.

For other options or clauses in the definition, they are added to the options or clauses of the statement that references the view, but the effect is undefined. For example, if a view definition includes a `LIMIT` clause, and you select from the view using a statement that has its own `LIMIT` clause, it is undefined which limit applies. This same principle applies to options such as `ALL`, `DISTINCT`, or `SQL_SMALL_RESULT` that follow the `SELECT` keyword, and to clauses such as `INTO`, `FOR UPDATE`, `LOCK IN SHARE MODE`, and `PROCEDURE`.

If you create a view and then change the query processing environment by changing system variables, that may affect the results that you get from the view:

```
mysql> CREATE VIEW v (mycol) AS SELECT 'abc';
Query OK, 0 rows affected (0.01 sec)

mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT "mycol" FROM v;
+-----+
| mycol |
+-----+
| mycol |
+-----+
1 row in set (0.01 sec)
```

```
mysql> SET sql_mode = 'ANSI_QUOTES';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT "mycol" FROM v;
+-----+
| mycol |
+-----+
| abc   |
+-----+
1 row in set (0.00 sec)
```

The **DEFINER** and **SQL SECURITY** clauses specify the security context to be used when checking access privileges at view invocation time. They were added in MySQL 5.1.2.

CURRENT_USER also can be given as **CURRENT_USER()**.

Within a stored routine that is defined with the **SQL SECURITY DEFINER** characteristic, **CURRENT_USER** returns the routine creator. This also affects a view defined within such a routine, if the view definition contains a **DEFINER** value of **CURRENT_USER**.

The default **DEFINER** value is the user who executes the **CREATE VIEW** statement. (This is the same as **DEFINER = CURRENT_USER**.) If a *user* value is given, it should be a MySQL account in '*user_name*'@'*host_name*' format (the same format used in the **GRANT** statement). The *user_name* and *host_name* values both are required.

If you specify the **DEFINER** clause, you cannot set the value to any user but your own unless you have the **SUPER** privilege. These rules determine the legal **DEFINER** user values:

- If you do not have the **SUPER** privilege, the only legal *user* value is your own account, either specified literally or by using **CURRENT_USER**. You cannot set the definer to some other account.
- If you have the **SUPER** privilege, you can specify any syntactically legal account name. If the account does not actually exist, a warning is generated.

The **SQL SECURITY** characteristic determines which MySQL account to use when checking access privileges for the view when the view is executed. The legal characteristic values are **DEFINER** and **INVOKER**. These indicate that the view must be executable by the user who defined it or invoked it, respectively. The default **SQL SECURITY** value is **DEFINER**.

As of MySQL 5.1.2 (when the **DEFINER** and **SQL SECURITY** clauses were implemented), view privileges are checked like this:

- At view definition time, the view creator must have the privileges needed to use the top-level objects accessed by the view. For example, if the view definition refers to a stored function, only the privileges needed to invoke the function can be checked. The privileges required when the function runs can be checked only as it executes: For different invocations of the function, different execution paths within the function might be taken.
- At view execution time, privileges for objects accessed by the view are checked against the privileges held by the view creator or invoker, depending on whether the **SQL SECURITY** characteristic is **DEFINER** or **INVOKER**, respectively.
- If view execution causes execution of a stored function, privilege checking for statements executed within the function depend on whether the function is defined with a **SQL SECURITY** characteristic of **DEFINER** or **INVOKER**. If the security characteristic is **DEFINER**, the function runs with the privileges of its creator. If the characteristic is **INVOKER**, the function runs with the privileges determined by the view's **SQL SECURITY** characteristic.

Prior to MySQL 5.1.2 (before the **DEFINER** and **SQL SECURITY** clauses were implemented), privileges required for objects used in a view are checked at view creation time.

Example: A view might depend on a stored function, and that function might invoke other stored routines. For example, the following view invokes a stored function **f()**:

```
CREATE VIEW v AS SELECT * FROM t WHERE t.id = f(t.name);
```

Suppose that **f()** contains a statement such as this:

```
IF name IS NULL then
  CALL p1();
ELSE
  CALL p2();
END IF;
```

The privileges required for executing statements within `f()` need to be checked when `f()` executes. This might mean that privileges are needed for `p1()` or `p2()`, depending on the execution path within `f()`. Those privileges need to be checked at runtime, and the user who must possess the privileges is determined by the `SQL SECURITY` values of the function `f()` and the view `v`.

The `DEFINER` and `SQL SECURITY` clauses for views are extensions to standard SQL. In standard SQL, views are handled using the rules for `SQL SECURITY INVOKER`.

If you invoke a view that was created before MySQL 5.0.13/5.1.2, it is treated as though it was created with a `SQL SECURITY DEFINER` clause and with a `DEFINER` value that is the same as your account. However, because the actual definer is unknown, MySQL issues a warning. To make the warning go away, it is sufficient to re-create the view so that the view definition includes a `DEFINER` clause.

The optional `ALGORITHM` clause is a MySQL extension to standard SQL. `ALGORITHM` takes three values: `MERGE`, `TEMPTABLE`, or `UNDEFINED`. The default algorithm is `UNDEFINED` if no `ALGORITHM` clause is present. The algorithm affects how MySQL processes the view.

For `MERGE`, the text of a statement that refers to the view and the view definition are merged such that parts of the view definition replace corresponding parts of the statement.

For `TEMPTABLE`, the results from the view are retrieved into a temporary table, which then is used to execute the statement.

For `UNDEFINED`, MySQL chooses which algorithm to use. It prefers `MERGE` over `TEMPTABLE` if possible, because `MERGE` is usually more efficient and because a view cannot be updatable if a temporary table is used.

A reason to choose `TEMPTABLE` explicitly is that locks can be released on underlying tables after the temporary table has been created and before it is used to finish processing the statement. This might result in quicker lock release than the `MERGE` algorithm so that other clients that use the view are not blocked as long.

A view algorithm can be `UNDEFINED` for three reasons:

- No `ALGORITHM` clause is present in the `CREATE VIEW` statement.
- The `CREATE VIEW` statement has an explicit `ALGORITHM = UNDEFINED` clause.
- `ALGORITHM = MERGE` is specified for a view that can be processed only with a temporary table. In this case, MySQL generates a warning and sets the algorithm to `UNDEFINED`.

As mentioned earlier, `MERGE` is handled by merging corresponding parts of a view definition into the statement that refers to the view. The following examples briefly illustrate how the `MERGE` algorithm works. The examples assume that there is a view `v_merge` that has this definition:

```
CREATE ALGORITHM = MERGE VIEW v_merge (vc1, vc2) AS
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 1: Suppose that we issue this statement:

```
SELECT * FROM v_merge;
```

MySQL handles the statement as follows:

- `v_merge` becomes `t`
- `*` becomes `vc1, vc2`, which corresponds to `c1, c2`
- The view `WHERE` clause is added

The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 2: Suppose that we issue this statement:

```
SELECT * FROM v_merge WHERE vc1 < 100;
```

This statement is handled similarly to the previous one, except that `vc1 < 100` becomes `c1 < 100` and the view `WHERE` clause is added to the statement `WHERE` clause using an `AND` connective (and parentheses are added to make sure the parts of the clause are executed with correct precedence). The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE (c3 > 100) AND (c1 < 100);
```

Effectively, the statement to be executed has a `WHERE` clause of this form:

```
WHERE (select WHERE) AND (view WHERE)
```

The `MERGE` algorithm requires a one-to-one relationship between the rows in the view and the rows in the underlying table. If this relationship does not hold, a temporary table must be used instead. Lack of a one-to-one relationship occurs if the view contains any of a number of constructs:

- Aggregate functions (`SUM()`, `MIN()`, `MAX()`, `COUNT()`, and so forth)
- `DISTINCT`
- `GROUP BY`
- `HAVING`
- `UNION` or `UNION ALL`
- Subquery in the select list
- Refers only to literal values (in this case, there is no underlying table)

Some views are updatable. That is, you can use them in statements such as `UPDATE`, `DELETE`, or `INSERT` to update the contents of the underlying table. For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view non-updatable. To be more specific, a view is not updatable if it contains any of the following:

- Aggregate functions (`SUM()`, `MIN()`, `MAX()`, `COUNT()`, and so forth)
- `DISTINCT`
- `GROUP BY`
- `HAVING`
- `UNION` or `UNION ALL`
- Subquery in the select list
- Certain joins (see additional join discussion later in this section)
- Non-updatable view in the `FROM` clause
- A subquery in the `WHERE` clause that refers to a table in the `FROM` clause
- Refers only to literal values (in this case, there is no underlying table to update)
- `ALGORITHM = TEMPTABLE` (use of a temporary table always makes a view non-updatable)

With respect to insertability (being updatable with `INSERT` statements), an updatable view is insertable if it also satisfies these additional requirements for the view columns:

- There must be no duplicate view column names.
- The view must contain all columns in the base table that do not have a default value.
- The view columns must be simple column references and not derived columns. A derived column is one that is not a simple column reference but is derived from an expression. These are examples of derived columns:

```
3.14159
col1 + 3
UPPER(col2)
col3 / col4
(subquery)
```

A view that has a mix of simple column references and derived columns is not insertable, but it can be updatable if you update only those columns that are not derived. Consider this view:

```
CREATE VIEW v AS SELECT col1, 1 AS col2 FROM t;
```

This view is not insertable because `col2` is derived from an expression. But it is updatable if the update does not try to update `col2`. This update is allowable:

```
UPDATE v SET col1 = 0;
```

This update is not allowable because it attempts to update a derived column:

```
UPDATE v SET col2 = 0;
```

It is sometimes possible for a multiple-table view to be updatable, assuming that it can be processed with the `MERGE` algorithm. For this to work, the view must use an inner join (not an outer join or a `UNION`). Also, only a single table in the view definition can be updated, so the `SET` clause must name only columns from one of the tables in the view. Views that use `UNION ALL` are disallowed even though they might be theoretically updatable, because the implementation uses temporary tables to process them.

For a multiple-table updatable view, `INSERT` can work if it inserts into a single table. `DELETE` is not supported.

`INSERT DELAYED` is not supported for views.

If a table contains an `AUTO_INCREMENT` column, inserting into an insertable view on the table that does not include the `AUTO_INCREMENT` column does not change the value of `LAST_INSERT_ID()`, because the side effects of inserting default values into columns not part of the view should not be visible.

The `WITH CHECK OPTION` clause can be given for an updatable view to prevent inserts or updates to rows except those for which the `WHERE` clause in the *select_statement* is true.

In a `WITH CHECK OPTION` clause for an updatable view, the `LOCAL` and `CASCADED` keywords determine the scope of check testing when the view is defined in terms of another view. The `LOCAL` keyword restricts the `CHECK OPTION` only to the view being defined. `CASCADED` causes the checks for underlying views to be evaluated as well. When neither keyword is given, the default is `CASCADED`. Consider the definitions for the following table and set of views:

```
mysql> CREATE TABLE t1 (a INT);
mysql> CREATE VIEW v1 AS SELECT * FROM t1 WHERE a < 2
-> WITH CHECK OPTION;
mysql> CREATE VIEW v2 AS SELECT * FROM v1 WHERE a > 0
-> WITH LOCAL CHECK OPTION;
mysql> CREATE VIEW v3 AS SELECT * FROM v1 WHERE a > 0
-> WITH CASCADED CHECK OPTION;
```

Here the `v2` and `v3` views are defined in terms of another view, `v1`. `v2` has a `LOCAL` check option, so inserts are tested only against the `v2` check. `v3` has a `CASCADED` check option, so inserts are tested not only against its own check, but against those of underlying views. The following statements illustrate these differences:

```
mysql> INSERT INTO v2 VALUES (2);
Query OK, 1 row affected (0.00 sec)
mysql> INSERT INTO v3 VALUES (2);
ERROR 1369 (HY000): CHECK OPTION failed 'test.v3'
```

MySQL sets a flag, called the view updatability flag, at `CREATE VIEW` time. The flag is set to `YES` (true) if `UPDATE` and `DELETE`

(and similar operations) are legal for the view. Otherwise, the flag is set to **NO** (false). The **IS_UPDATABLE** column in the **INFORMATION_SCHEMA.VIEWS** table displays the status of this flag. It means that the server always knows whether a view is updatable. If the view is not updatable, statements such **UPDATE**, **DELETE**, and **INSERT** are illegal and will be rejected. (Note that even if a view is updatable, it might not be possible to insert into it, as described elsewhere in this section.)

The updatability of views may be affected by the value of the **updatable_views_with_limit** system variable. See [Section 5.2.3, “System Variables”](#).

22.3. DROP VIEW Syntax

```
DROP VIEW [IF EXISTS]
  view_name [, view_name] ...
[RESTRICT | CASCADE]
```

DROP VIEW removes one or more views. You must have the **DROP** privilege for each view. If any of the views named in the argument list do not exist, MySQL returns an error indicating by name which non-existing views it was unable to drop, but it also drops all of the views in the list that do exist.

The **IF EXISTS** clause prevents an error from occurring for views that don't exist. When this clause is given, a **NOTE** is generated for each non-existent view. See [Section 12.5.4.32, “SHOW WARNINGS Syntax”](#).

RESTRICT and **CASCADE**, if given, are parsed and ignored.

Chapter 23. The `INFORMATION_SCHEMA` Database

`INFORMATION_SCHEMA` provides access to database metadata.

Metadata is data about the data, such as the name of a database or table, the data type of a column, or access privileges. Other terms that sometimes are used for this information are *data dictionary* and *system catalog*.

`INFORMATION_SCHEMA` is the information database, the place that stores information about all the other databases that the MySQL server maintains. Inside `INFORMATION_SCHEMA` there are several read-only tables. They are actually views, not base tables, so there are no files associated with them.

In effect, we have a database named `INFORMATION_SCHEMA`, although the server does not create a database directory with that name. It is possible to select `INFORMATION_SCHEMA` as the default database with a `USE` statement, but it is possible only to read the contents of tables. You cannot insert into them, update them, or delete from them.

Here is an example of a statement that retrieves information from `INFORMATION_SCHEMA`:

```
mysql> SELECT table_name, table_type, engine
-> FROM information_schema.tables
-> WHERE table_schema = 'db5'
-> ORDER BY table_name DESC;
```

table_name	table_type	engine
v56	VIEW	NULL
v3	VIEW	NULL
v2	VIEW	NULL
v	VIEW	NULL
tables	BASE TABLE	MyISAM
t7	BASE TABLE	MyISAM
t3	BASE TABLE	MyISAM
t2	BASE TABLE	MyISAM
t	BASE TABLE	MyISAM
pk	BASE TABLE	InnoDB
loop	BASE TABLE	MyISAM
kurs	BASE TABLE	MyISAM
k	BASE TABLE	MyISAM
into	BASE TABLE	MyISAM
goto	BASE TABLE	MyISAM
fk2	BASE TABLE	InnoDB
fk	BASE TABLE	InnoDB

17 rows in set (0.01 sec)

Explanation: The statement requests a list of all the tables in database `db5`, in reverse alphabetical order, showing just three pieces of information: the name of the table, its type, and its storage engine.

Each MySQL user has the right to access these tables, but can see only the rows in the tables that correspond to objects for which the user has the proper access privileges. In some cases (for example, the `ROUTINE_DEFINITION` column in the `INFORMATION_SCHEMA.ROUTINES` table), users who have insufficient privileges will see `NULL`.

The `SELECT ... FROM INFORMATION_SCHEMA` statement is intended as a more consistent way to provide access to the information provided by the various `SHOW` statements that MySQL supports (`SHOW DATABASES`, `SHOW TABLES`, and so forth). Using `SELECT` has these advantages, compared to `SHOW`:

- It conforms to Codd's rules. That is, all access is done on tables.
- Nobody needs to learn a new statement syntax. Because they already know how `SELECT` works, they only need to learn the object names.
- The implementor need not worry about adding keywords.
- There are millions of possible output variations, instead of just one. This provides more flexibility for applications that have varying requirements about what metadata they need.
- Migration is easier because every other DBMS does it this way.

However, because `SHOW` is popular with MySQL employees and users, and because it might be confusing were it to disappear, the advantages of conventional syntax are not a sufficient reason to eliminate `SHOW`. In fact, along with the implementation of `INFORMA-`

`INFORMATION_SCHEMA`, there are enhancements to `SHOW` as well. These are described in [Section 23.27, “Extensions to SHOW Statements”](#).

There is no difference between the privileges required for `SHOW` statements and those required to select information from `INFORMATION_SCHEMA`. In either case, you have to have some privilege on an object in order to see information about it.

The implementation for the `INFORMATION_SCHEMA` table structures in MySQL follows the ANSI/ISO SQL:2003 standard Part 11 *Schemata*. Our intent is approximate compliance with SQL:2003 core feature F021 *Basic information schema*.

Users of SQL Server 2000 (which also follows the standard) may notice a strong similarity. However, MySQL has omitted many columns that are not relevant for our implementation, and added columns that are MySQL-specific. One such column is the `ENGINE` column in the `INFORMATION_SCHEMA.TABLES` table.

Although other DBMSs use a variety of names, like `syscat` or `system`, the standard name is `INFORMATION_SCHEMA`.

The following sections describe each of the tables and columns that are in `INFORMATION_SCHEMA`. For each column, there are three pieces of information:

- “`INFORMATION_SCHEMA` Name” indicates the name for the column in the `INFORMATION_SCHEMA` table. This corresponds to the standard SQL name unless the “Remarks” field says “MySQL extension.”
- “`SHOW` Name” indicates the equivalent field name in the closest `SHOW` statement, if there is one.
- “Remarks” provides additional information where applicable. If this field is `NULL`, it means that the value of the column is always `NULL`. If this field says “MySQL extension,” the column is a MySQL extension to standard SQL.

To avoid using any name that is reserved in the standard or in DB2, SQL Server, or Oracle, we changed the names of some columns marked “MySQL extension”. (For example, we changed `COLLATION` to `TABLE_COLLATION` in the `TABLES` table.) See the list of reserved words near the end of this article: <http://web.archive.org/web/20030201202307/www.dbazine.com/gulutzan5.html>.

The definition for character columns (for example, `TABLES.TABLE_NAME`) is generally `VARCHAR(N) CHARACTER SET utf8` where `N` is at least 64. MySQL uses the default collation for this character set (`utf8_general_ci`) for all searches, sorts, comparisons, and other string operations on such columns. If the default collation is not correct for your needs, you can force a suitable collation with a `COLLATE` clause ([Section 9.5.1, “Using COLLATE in SQL Statements”](#)).

Each section indicates what `SHOW` statement is equivalent to a `SELECT` that retrieves information from `INFORMATION_SCHEMA`, if there is such a statement.

Note

At present, there are some missing columns and some columns out of order. We are working on this and updating the documentation as changes are made.

For answers to questions that are often asked concerning the `INFORMATION_SCHEMA` database, see [Section A.7, “MySQL 5.0 FAQ — INFORMATION_SCHEMA”](#).

23.1. The `INFORMATION_SCHEMA` `SCHEMATA` Table

A schema is a database, so the `SCHEMATA` table provides information about databases.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>CATALOG_NAME</code>		<code>NULL</code>
<code>SCHEMA_NAME</code>		Database
<code>DEFAULT_CHARACTER_SET_NAME</code>		
<code>DEFAULT_COLLATION_NAME</code>		
<code>SQL_PATH</code>		<code>NULL</code>

The following statements are equivalent:

```
SELECT SCHEMA_NAME AS `Database`
FROM INFORMATION_SCHEMA.SCHEMATA
[WHERE SCHEMA_NAME LIKE 'wild']
```

```
SHOW DATABASES
[LIKE 'wild']
```

23.2. The `INFORMATION_SCHEMA TABLES` Table

The `TABLES` table provides information about tables in databases.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>TABLE_CATALOG</code>		<code>NULL</code>
<code>TABLE_SCHEMA</code>	<code>Table_...</code>	
<code>TABLE_NAME</code>	<code>Table_...</code>	
<code>TABLE_TYPE</code>		
<code>ENGINE</code>	<code>Engine</code>	MySQL extension
<code>VERSION</code>	<code>Version</code>	MySQL extension
<code>ROW_FORMAT</code>	<code>Row_format</code>	MySQL extension
<code>TABLE_ROWS</code>	<code>Rows</code>	MySQL extension
<code>AVG_ROW_LENGTH</code>	<code>Avg_row_length</code>	MySQL extension
<code>DATA_LENGTH</code>	<code>Data_length</code>	MySQL extension
<code>MAX_DATA_LENGTH</code>	<code>Max_data_length</code>	MySQL extension
<code>INDEX_LENGTH</code>	<code>Index_length</code>	MySQL extension
<code>DATA_FREE</code>	<code>Data_free</code>	MySQL extension
<code>AUTO_INCREMENT</code>	<code>Auto_increment</code>	MySQL extension
<code>CREATE_TIME</code>	<code>Create_time</code>	MySQL extension
<code>UPDATE_TIME</code>	<code>Update_time</code>	MySQL extension
<code>CHECK_TIME</code>	<code>Check_time</code>	MySQL extension
<code>TABLE_COLLATION</code>	<code>Collation</code>	MySQL extension
<code>CHECKSUM</code>	<code>Checksum</code>	MySQL extension
<code>CREATE_OPTIONS</code>	<code>Create_options</code>	MySQL extension
<code>TABLE_COMMENT</code>	<code>Comment</code>	MySQL extension

Notes:

- `TABLE_SCHEMA` and `TABLE_NAME` are a single field in a `SHOW` display, for example `Table_in_db1`.
- `TABLE_TYPE` should be `BASE TABLE` or `VIEW`. If table is temporary, then `TABLE_TYPE` = `TEMPORARY`. (There are no temporary views, so this is not ambiguous.)
- For partitioned tables, beginning with MySQL 5.1.9, the `ENGINE` column shows the name of the storage engine used by all partitions. (Previously, this column showed `PARTITION` for such tables.)
- The `TABLE_ROWS` column is `NULL` if the table is in the `INFORMATION_SCHEMA` database. For `InnoDB` tables, the row count is only a rough estimate used in SQL optimization.
- For tables using the `NDBCLUSTER` storage engine, beginning with MySQL 5.1.12, the `DATA_LENGTH` column reflects the true amount of storage for variable-width columns. (See [Bug#18413](#).)

Note

Because MySQL Cluster allocates storage for variable-width columns in 10-page extents of 32 kilobytes each, space usage for such columns is reported in increments of 320 KB.

- We have nothing for the table's default character set. `TABLE_COLLATION` is close, because collation names begin with a character set name.

- Beginning with MySQL 5.1.9, the `CREATE_OPTIONS` column shows `partitioned` if the table is partitioned.

The following statements are equivalent:

```
SELECT table_name FROM INFORMATION_SCHEMA.TABLES
[WHERE table_schema = 'db_name']
[WHERE|AND table_name LIKE 'wild']

SHOW TABLES
[FROM db_name]
[LIKE 'wild']
```

23.3. The INFORMATION_SCHEMA COLUMNS Table

The `COLUMNS` table provides information about columns in tables.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA		
TABLE_NAME		
COLUMN_NAME	Field	
ORDINAL_POSITION		see notes
COLUMN_DEFAULT	Default	
IS_NULLABLE	Null	
DATA_TYPE	Type	
CHARACTER_MAXIMUM_LENGTH	Type	
CHARACTER_OCTET_LENGTH		
NUMERIC_PRECISION	Type	
NUMERIC_SCALE	Type	
CHARACTER_SET_NAME		
COLLATION_NAME	Collation	
COLUMN_TYPE	Type	MySQL extension
COLUMN_KEY	Key	MySQL extension
EXTRA	Extra	MySQL extension
COLUMN_COMMENT	Comment	MySQL extension

Notes:

- In `SHOW`, the `Type` display includes values from several different `COLUMNS` columns.
- `ORDINAL_POSITION` is necessary because you might want to say `ORDER BY ORDINAL_POSITION`. Unlike `SHOW`, `SELECT` does not have automatic ordering.
- `CHARACTER_OCTET_LENGTH` should be the same as `CHARACTER_MAXIMUM_LENGTH`, except for multi-byte character sets.
- `CHARACTER_SET_NAME` can be derived from `Collation`. For example, if you say `SHOW FULL COLUMNS FROM t`, and you see in the `Collation` column a value of `latin1_swedish_ci`, the character set is what's before the first underscore: `latin1`.

The following statements are nearly equivalent:

```
SELECT COLUMN_NAME, DATA_TYPE, IS_NULLABLE, COLUMN_DEFAULT
FROM INFORMATION_SCHEMA.COLUMNS
WHERE table_name = 'tbl_name'
[AND table_schema = 'db_name']
[AND column_name LIKE 'wild']
```

```
SHOW COLUMNS
FROM tbl_name
[FROM db_name]
[LIKE 'wild']
```

23.4. The INFORMATION_SCHEMA STATISTICS Table

The `STATISTICS` table provides information about table indexes.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA		= Database
TABLE_NAME	Table	
NON_UNIQUE	Non_unique	
INDEX_SCHEMA		= Database
INDEX_NAME	Key_name	
SEQ_IN_INDEX	Seq_in_index	
COLUMN_NAME	Column_name	
COLLATION	Collation	
CARDINALITY	Cardinality	
SUB_PART	Sub_part	MySQL extension
PACKED	Packed	MySQL extension
NULLABLE	Null	MySQL extension
INDEX_TYPE	Index_type	MySQL extension
COMMENT	Comment	MySQL extension

Notes:

- There is no standard table for indexes. The preceding list is similar to what SQL Server 2000 returns for `sp_statistics`, except that we replaced the name `QUALIFIER` with `CATALOG` and we replaced the name `OWNER` with `SCHEMA`.

Clearly, the preceding table and the output from `SHOW INDEX` are derived from the same parent. So the correlation is already close.

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.STATISTICS
WHERE table_name = 'tbl_name'
[AND table_schema = 'db_name']

SHOW INDEX
FROM tbl_name
[FROM db_name]
```

23.5. The INFORMATION_SCHEMA USER_PRIVILEGES Table

The `USER_PRIVILEGES` table provides information about global privileges. This information comes from the `mysql.user` grant table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
GRANTEE		' <i>user_name</i> '@' <i>host_name</i> ' value, MySQL extension
TABLE_CATALOG		NULL, MySQL extension
PRIVILEGE_TYPE		MySQL extension

<code>IS_GRANTABLE</code>		MySQL extension

Notes:

- This is a non-standard table. It takes its values from the `mysql.user` table.

23.6. The `INFORMATION_SCHEMA SCHEMA_PRIVILEGES` Table

The `SCHEMA_PRIVILEGES` table provides information about schema (database) privileges. This information comes from the `mysql.db` grant table.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>GRANTEE</code>		' <i>user_name</i> '@' <i>host_name</i> ' value, MySQL extension
<code>TABLE_CATALOG</code>		<code>NULL</code> , MySQL extension
<code>TABLE_SCHEMA</code>		MySQL extension
<code>PRIVILEGE_TYPE</code>		MySQL extension
<code>IS_GRANTABLE</code>		MySQL extension

Notes:

- This is a non-standard table. It takes its values from the `mysql.db` table.

23.7. The `INFORMATION_SCHEMA TABLE_PRIVILEGES` Table

The `TABLE_PRIVILEGES` table provides information about table privileges. This information comes from the `mysql.tables_priv` grant table.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>GRANTEE</code>		' <i>user_name</i> '@' <i>host_name</i> ' value
<code>TABLE_CATALOG</code>		<code>NULL</code>
<code>TABLE_SCHEMA</code>		
<code>TABLE_NAME</code>		
<code>PRIVILEGE_TYPE</code>		
<code>IS_GRANTABLE</code>		

Notes:

- `PRIVILEGE_TYPE` can contain one (and only one) of these values: `SELECT`, `INSERT`, `UPDATE`, `REFERENCES`, `ALTER`, `INDEX`, `DROP`, `CREATE VIEW`.

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.TABLE_PRIVILEGES
SHOW GRANTS ...
```

23.8. The `INFORMATION_SCHEMA COLUMN_PRIVILEGES` Table

The `COLUMN_PRIVILEGES` table provides information about column privileges. This information comes from the `mysql.columns_priv` grant table.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>GRANTEE</code>		' <i>user_name</i> '@' <i>host_name</i> ' value
<code>TABLE_CATALOG</code>		NULL
<code>TABLE_SCHEMA</code>		
<code>TABLE_NAME</code>		
<code>COLUMN_NAME</code>		
<code>PRIVILEGE_TYPE</code>		
<code>IS_GRANTABLE</code>		

Notes:

- In the output from `SHOW FULL COLUMNS`, the privileges are all in one field and in lowercase, for example, `select, insert, update, references`. In `COLUMN_PRIVILEGES`, there is one privilege per row, in uppercase.
- `PRIVILEGE_TYPE` can contain one (and only one) of these values: `SELECT`, `INSERT`, `UPDATE`, `REFERENCES`.
- If the user has `GRANT OPTION` privilege, `IS_GRANTABLE` should be `YES`. Otherwise, `IS_GRANTABLE` should be `NO`. The output does not list `GRANT OPTION` as a separate privilege.

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.COLUMN_PRIVILEGES
SHOW GRANTS ...
```

23.9. The `INFORMATION_SCHEMA CHARACTER_SETS` Table

The `CHARACTER_SETS` table provides information about available character sets.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>CHARACTER_SET_NAME</code>	Charset	
<code>DEFAULT_COLLATE_NAME</code>	Default collation	
<code>DESCRIPTION</code>	Description	MySQL extension
<code>MAXLEN</code>	Maxlen	MySQL extension

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.CHARACTER_SETS
[WHERE name LIKE 'wild']
SHOW CHARACTER SET
[LIKE 'wild']
```

23.10. The `INFORMATION_SCHEMA COLLATIONS` Table

The `COLLATIONS` table provides information about collations for each character set.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>COLLATION_NAME</code>	Collation	
<code>CHARACTER_SET_NAME</code>	Charset	MySQL extension

ID	Id	MySQL extension
IS_DEFAULT	Default	MySQL extension
IS_COMPILED	Compiled	MySQL extension
SORTLEN	Sortlen	MySQL extension

The following statements are equivalent:

```
SELECT COLLATION_NAME FROM INFORMATION_SCHEMA.COLLATIONS
[WHERE collation_name LIKE 'wild']

SHOW COLLATION
[LIKE 'wild']
```

23.11. The INFORMATION_SCHEMA COLLATION_CHARACTER_SET_APPLICABILITY Table

The `COLLATION_CHARACTER_SET_APPLICABILITY` table indicates what character set is applicable for what collation. The columns are equivalent to the first two display fields that we get from `SHOW COLLATION`.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
COLLATION_NAME	Collation	
CHARACTER_SET_NAME	Charset	

23.12. The INFORMATION_SCHEMA TABLE_CONSTRAINTS Table

The `TABLE_CONSTRAINTS` table describes which tables have constraints.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
CONSTRAINT_CATALOG		NULL
CONSTRAINT_SCHEMA		
CONSTRAINT_NAME		
TABLE_SCHEMA		
TABLE_NAME		
CONSTRAINT_TYPE		

Notes:

- The `CONSTRAINT_TYPE` value can be `UNIQUE`, `PRIMARY KEY`, or `FOREIGN KEY`.
- The `UNIQUE` and `PRIMARY KEY` information is about the same as what you get from the `key_name` field in the output from `SHOW INDEX` when the `Non_unique` field is 0.
- The `CONSTRAINT_TYPE` column can contain one of these values: `UNIQUE`, `PRIMARY KEY`, `FOREIGN KEY`, `CHECK`. This is a `CHAR` (not `ENUM`) column. The `CHECK` value is not available until we support `CHECK`.

23.13. The INFORMATION_SCHEMA KEY_COLUMN_USAGE Table

The `KEY_COLUMN_USAGE` table describes which key columns have constraints.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
CONSTRAINT_CATALOG		NULL

CONSTRAINT_SCHEMA		
CONSTRAINT_NAME		
TABLE_CATALOG		
TABLE_SCHEMA		
TABLE_NAME		
COLUMN_NAME		
ORDINAL_POSITION		
POSITION_IN_UNIQUE_CONSTRAINT		
REFERENCED_TABLE_SCHEMA		
REFERENCED_TABLE_NAME		
REFERENCED_COLUMN_NAME		

Notes:

- If the constraint is a foreign key, then this is the column of the foreign key, not the column that the foreign key references.
- The value of **ORDINAL_POSITION** is the column's position within the constraint, not the column's position within the table. Column positions are numbered beginning with 1.
- The value of **POSITION_IN_UNIQUE_CONSTRAINT** is **NULL** for unique and primary-key constraints. For foreign-key constraints, it is the ordinal position in key of the table that is being referenced.

For example, suppose that there are two tables name **t1** and **t3** that have the following definitions:

```
CREATE TABLE t1
(
  s1 INT,
  s2 INT,
  s3 INT,
  PRIMARY KEY(s3)
) ENGINE=InnoDB;

CREATE TABLE t3
(
  s1 INT,
  s2 INT,
  s3 INT,
  KEY(s1),
  CONSTRAINT CO FOREIGN KEY (s2) REFERENCES t1(s3)
) ENGINE=InnoDB;
```

For those two tables, the **KEY_COLUMN_USAGE** table has two rows:

- One row with **CONSTRAINT_NAME** = 'PRIMARY', **TABLE_NAME** = 't1', **COLUMN_NAME** = 's3', **ORDINAL_POSITION** = 1, **POSITION_IN_UNIQUE_CONSTRAINT** = **NULL**.
- One row with **CONSTRAINT_NAME** = 'CO', **TABLE_NAME** = 't3', **COLUMN_NAME** = 's2', **ORDINAL_POSITION** = 1, **POSITION_IN_UNIQUE_CONSTRAINT** = 1.

23.14. The INFORMATION_SCHEMA ROUTINES Table

The **ROUTINES** table provides information about stored routines (both procedures and functions). The **ROUTINES** table does not include user-defined functions (UDFs) at this time.

The column named “**mysql.proc name**” indicates the **mysql.proc** table column that corresponds to the **INFORMATION_SCHEMA.ROUTINES** table column, if any.

INFORMATION_SCHEMA Name	mysql.proc Name	Remarks
SPECIFIC_NAME	specific_name	
ROUTINE_CATALOG		NULL

ROUTINE_SCHEMA	db	
ROUTINE_NAME	name	
ROUTINE_TYPE	type	{PROCEDURE FUNCTION}
DTD_IDENTIFIER		(data type descriptor)
ROUTINE_BODY		SQL
ROUTINE_DEFINITION	body	
EXTERNAL_NAME		NULL
EXTERNAL_LANGUAGE	language	NULL
PARAMETER_STYLE		SQL
IS_DETERMINISTIC	is_deterministic	
SQL_DATA_ACCESS	sql_data_access	
SQL_PATH		NULL
SECURITY_TYPE	security_type	
CREATED	created	
LAST_ALTERED	modified	
SQL_MODE	sql_mode	MySQL extension
ROUTINE_COMMENT	comment	MySQL extension
DEFINER	definer	MySQL extension
CHARACTER_SET_CLIENT		MySQL extension
COLLATION_CONNECTION		MySQL extension
DATABASE_COLLATION		MySQL extension

Notes:

- MySQL calculates `EXTERNAL_LANGUAGE` thus:
 - If `mysql.proc.language='SQL'`, `EXTERNAL_LANGUAGE` is `NULL`
 - Otherwise, `EXTERNAL_LANGUAGE` is what is in `mysql.proc.language`. However, we do not have external languages yet, so it is always `NULL`.
- `CHARACTER_SET_CLIENT` is the session value of the `character_set_client` system variable when the routine was created. `COLLATION_CONNECTION` is the session value of the `collation_connection` system variable when the routine was created. `DATABASE_COLLATION` is the collation of the database with which the routine is associated. These columns were added in MySQL 5.1.21.

23.15. The INFORMATION_SCHEMA VIEWS Table

The `VIEWS` table provides information about views in databases. You must have the `SHOW VIEW` privilege to access this table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA		
TABLE_NAME		
VIEW_DEFINITION		
CHECK_OPTION		
IS_UPDATABLE		
DEFINER		
SECURITY_TYPE		

<code>CHARACTER_SET_CLIENT</code>		MySQL extension
<code>COLLATION_CONNECTION</code>		MySQL extension

Notes:

- The `VIEW_DEFINITION` column has most of what you see in the `Create Table` field that `SHOW CREATE VIEW` produces. Skip the words before `SELECT` and skip the words `WITH CHECK OPTION`. Suppose that the original statement was:

```
CREATE VIEW v AS
  SELECT s2,s1 FROM t
 WHERE s1 > 5
 ORDER BY s1
 WITH CHECK OPTION;
```

Then the view definition looks like this:

```
SELECT s2,s1 FROM t WHERE s1 > 5 ORDER BY s1
```

- The `CHECK_OPTION` column always has a value of `NONE`.
- MySQL sets a flag, called the view updatability flag, at `CREATE VIEW` time. The flag is set to `YES` (true) if `UPDATE` and `DELETE` (and similar operations) are legal for the view. Otherwise, the flag is set to `NO` (false). The `IS_UPDATABLE` column in the `VIEWS` table displays the status of this flag. It means that the server always knows whether a view is updatable. If the view is not updatable, statements such `UPDATE`, `DELETE`, and `INSERT` are illegal and will be rejected. (Note that even if a view is updatable, it might not be possible to insert into it; for details, refer to [Section 22.2, “CREATE VIEW Syntax”](#).)
- The `DEFINER` column indicates who defined the view. `SECURITY_TYPE` has a value of `DEFINER` or `INVOKER`.
- `CHARACTER_SET_CLIENT` is the session value of the `character_set_client` system variable when the view was created. `COLLATION_CONNECTION` is the session value of the `collation_connection` system variable when the view was created. These columns were added in MySQL 5.1.21.

23.16. The `INFORMATION_SCHEMA TRIGGERS` Table

The `TRIGGERS` table provides information about triggers. You must have the `SUPER` privilege to access this table.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>TRIGGER_CATALOG</code>		<code>NULL</code>
<code>TRIGGER_SCHEMA</code>		
<code>TRIGGER_NAME</code>	Trigger	
<code>EVENT_MANIPULATION</code>	Event	
<code>EVENT_OBJECT_CATALOG</code>		<code>NULL</code>
<code>EVENT_OBJECT_SCHEMA</code>		
<code>EVENT_OBJECT_TABLE</code>	Table	
<code>ACTION_ORDER</code>		0
<code>ACTION_CONDITION</code>		<code>NULL</code>
<code>ACTION_STATEMENT</code>	Statement	
<code>ACTION_ORIENTATION</code>		<code>ROW</code>
<code>ACTION_TIMING</code>	Timing	
<code>ACTION_REFERENCE_OLD_TABLE</code>		<code>NULL</code>
<code>ACTION_REFERENCE_NEW_TABLE</code>		<code>NULL</code>
<code>ACTION_REFERENCE_OLD_ROW</code>		<code>OLD</code>
<code>ACTION_REFERENCE_NEW_ROW</code>		<code>NEW</code>

CREATED		NULL (0)
SQL_MODE		MySQL extension
DEFINER		MySQL extension
CHARACTER_SET_CLIENT		MySQL extension
COLLATION_CONNECTION		MySQL extension
DATABASE_COLLATION		MySQL extension

Notes:

- The `TRIGGER_SCHEMA` and `TRIGGER_NAME` columns contain the name of the database in which the trigger occurs and the trigger name, respectively.
- The `EVENT_MANIPULATION` column contains one of the values 'INSERT', 'DELETE', or 'UPDATE'.
- As noted in [Chapter 20, Triggers](#), every trigger is associated with exactly one table. The `EVENT_OBJECT_SCHEMA` and `EVENT_OBJECT_TABLE` columns contain the database in which this table occurs, and the table's name.
- The `ACTION_ORDER` statement contains the ordinal position of the trigger's action within the list of all similar triggers on the same table. Currently, this value is always 0, because it is not possible to have more than one trigger with the same `EVENT_MANIPULATION` and `ACTION_TIMING` on the same table.
- The `ACTION_STATEMENT` column contains the statement to be executed when the trigger is invoked. This is the same as the text displayed in the `Statement` column of the output from `SHOW TRIGGERS`. Note that this text uses UTF-8 encoding.
- The `ACTION_ORIENTATION` column always contains the value 'ROW'.
- The `ACTION_TIMING` column contains one of the two values 'BEFORE' or 'AFTER'.
- The columns `ACTION_REFERENCE_OLD_ROW` and `ACTION_REFERENCE_NEW_ROW` contain the old and new column identifiers, respectively. This means that `ACTION_REFERENCE_OLD_ROW` always contains the value 'OLD' and `ACTION_REFERENCE_NEW_ROW` always contains the value 'NEW'.
- The `SQL_MODE` column shows the server SQL mode that was in effect at the time when the trigger was created (and thus which remains in effect for this trigger whenever it is invoked, *regardless of the current server SQL mode*). The possible range of values for this column is the same as that of the `sql_mode` system variable. See [Section 5.2.6, “SQL Modes”](#).
- The `DEFINER` column was added in MySQL 5.1.2. `DEFINER` indicates who defined the trigger.
- `CHARACTER_SET_CLIENT` is the session value of the `character_set_client` system variable when the trigger was created. `COLLATION_CONNECTION` is the session value of the `collation_connection` system variable when the trigger was created. `DATABASE_COLLATION` is the collation of the database with which the trigger is associated. These columns were added in MySQL 5.1.21.
- The following columns currently always contain NULL: `TRIGGER_CATALOG`, `EVENT_OBJECT_CATALOG`, `ACTION_CONDITION`, `ACTION_REFERENCE_OLD_TABLE`, `ACTION_REFERENCE_NEW_TABLE`, and `CREATED`.

Example, using the `ins_sum` trigger defined in [Section 20.3, “Using Triggers”](#):

```
mysql> SELECT * FROM INFORMATION_SCHEMA.TRIGGERS\G
***** 1. row *****
      TRIGGER_CATALOG: NULL
      TRIGGER_SCHEMA: test
      TRIGGER_NAME: ins_sum
      EVENT_MANIPULATION: INSERT
      EVENT_OBJECT_CATALOG: NULL
      EVENT_OBJECT_SCHEMA: test
      EVENT_OBJECT_TABLE: account
      ACTION_ORDER: 0
      ACTION_CONDITION: NULL
      ACTION_STATEMENT: SET @sum = @sum + NEW.amount
      ACTION_ORIENTATION: ROW
      ACTION_TIMING: BEFORE
      ACTION_REFERENCE_OLD_TABLE: NULL
      ACTION_REFERENCE_NEW_TABLE: NULL
      ACTION_REFERENCE_OLD_ROW: OLD
```

```

ACTION_REFERENCE_NEW_ROW: NEW
CREATED: NULL
SQL_MODE:
DEFINER: me@localhost

```

See also [Section 12.5.4.30, “SHOW TRIGGERS Syntax”](#).

23.17. The `INFORMATION_SCHEMA PLUGINS` Table

The `PLUGINS` table provides information about server plugins.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>PLUGIN_NAME</code>	Name	MySQL extension
<code>PLUGIN_VERSION</code>		MySQL extension
<code>PLUGIN_STATUS</code>	Status	MySQL extension
<code>PLUGIN_TYPE</code>	Type	MySQL extension
<code>PLUGIN_TYPE_VERSION</code>		MySQL extension
<code>PLUGIN_LIBRARY</code>	Library	MySQL extension
<code>PLUGIN_LIBRARY_VERSION</code>		MySQL extension
<code>PLUGIN_AUTHOR</code>		MySQL extension
<code>PLUGIN_DESCRIPTION</code>		MySQL extension
<code>PLUGIN_LICENSE</code>		MySQL extension

Notes:

- The `PLUGINS` table is a non-standard table. It was added in MySQL 5.1.5.
- The `PLUGIN_LICENSE` column was added in MySQL 5.1.12.

See also [Section 12.5.4.21, “SHOW PLUGINS Syntax”](#).

23.18. The `INFORMATION_SCHEMA ENGINES` Table

The `PLUGINS` table provides information about storage engines.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>ENGINE</code>	Engine	MySQL extension
<code>SUPPORT</code>	Support	MySQL extension
<code>COMMENT</code>	Comment	MySQL extension
<code>TRANSACTIONS</code>	Transactions	MySQL extension
<code>XA</code>	XA	MySQL extension
<code>SAVEPOINTS</code>	Savepoints	MySQL extension

Notes:

- The `ENGINES` table is a non-standard table. It was added in MySQL 5.1.5.

See also [Section 12.5.4.14, “SHOW ENGINES Syntax”](#).

23.19. The `INFORMATION_SCHEMA PARTITIONS` Table

The `PARTITIONS` table provides information about table partitions. See [Chapter 17, Partitioning](#), for more information about partitioning tables.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>TABLE_CATALOG</code>		MySQL extension
<code>TABLE_SCHEMA</code>		MySQL extension
<code>TABLE_NAME</code>		MySQL extension
<code>PARTITION_NAME</code>		MySQL extension
<code>SUBPARTITION_NAME</code>		MySQL extension
<code>PARTITION_ORDINAL_POSITION</code>		MySQL extension
<code>SUBPARTITION_ORDINAL_POSITION</code>		MySQL extension
<code>PARTITION_METHOD</code>		MySQL extension
<code>SUBPARTITION_METHOD</code>		MySQL extension
<code>PARTITION_EXPRESSION</code>		MySQL extension
<code>SUBPARTITION_EXPRESSION</code>		MySQL extension
<code>PARTITION_DESCRIPTION</code>		MySQL extension
<code>TABLE_ROWS</code>		MySQL extension
<code>AVG_ROW_LENGTH</code>		MySQL extension
<code>DATA_LENGTH</code>		MySQL extension
<code>MAX_DATA_LENGTH</code>		MySQL extension
<code>INDEX_LENGTH</code>		MySQL extension
<code>DATA_FREE</code>		MySQL extension
<code>CREATE_TIME</code>		MySQL extension
<code>UPDATE_TIME</code>		MySQL extension
<code>CHECK_TIME</code>		MySQL extension
<code>CHECKSUM</code>		MySQL extension
<code>PARTITION_COMMENT</code>		MySQL extension
<code>NODEGROUP</code>		MySQL extension
<code>TABLESPACE_NAME</code>		MySQL extension

Notes:

- The `PARTITIONS` table is a non-standard table. It was added in MySQL 5.1.6.
Each record in this table corresponds to an individual partition or subpartition of a partitioned table.
- `TABLE_CATALOG`: This column is always `NULL`.
- `TABLE_SCHEMA`: This column contains the name of the database to which the table belongs.
- `TABLE_NAME`: This column contains the name of the table containing the partition.
- `PARTITION_NAME`: The name of the partition.
- `SUBPARTITION_NAME`: If the `PARTITIONS` table record represents a subpartition, then this column contains the name of subpartition; otherwise it is `NULL`.
- `PARTITION_ORDINAL_POSITION`: All partitions are indexed in the same order as they are defined, with `1` being the number assigned to the first partition. The indexing can change as partitions are added, dropped, and reorganized; the number shown in this column reflects the current order, taking into account any indexing changes.
- `SUBPARTITION_ORDINAL_POSITION`: Subpartitions within a given partition are also indexed and reindexed in the same man-

ner as partitions are indexed within a table.

- **PARTITION_METHOD**: One of the values [RANGE](#), [LIST](#), [HASH](#), [LINEAR HASH](#), [KEY](#), or [LINEAR KEY](#); that is, one of the available partitioning types as discussed in [Section 17.2, “Partition Types”](#).
- **SUBPARTITION_METHOD**: One of the values [HASH](#), [LINEAR HASH](#), [KEY](#), or [LINEAR KEY](#); that is, one of the available subpartitioning types as discussed in [Section 17.2.5, “Subpartitioning”](#).
- **PARTITION_EXPRESSION**: This is the expression for the partitioning function used in the [CREATE TABLE](#) or [ALTER TABLE](#) statement that created the table's current partitioning scheme.

For example, consider a partitioned table created in the `test` database using this statement:

```
CREATE TABLE tp (
  c1 INT,
  c2 INT,
  c3 VARCHAR(25)
)
PARTITION BY HASH(c1 + c2)
PARTITIONS 4;
```

The **PARTITION_EXPRESSION** column in a **PARTITIONS** table record for a partition from this table displays `c1 + c2`, as shown here:

```
mysql> SELECT DISTINCT PARTITION_EXPRESSION
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_NAME='tp' AND TABLE_SCHEMA='test';
+-----+
| PARTITION_EXPRESSION |
+-----+
| c1 + c2              |
+-----+
1 row in set (0.09 sec)
```

- **SUBPARTITION_EXPRESSION**: This works in the same fashion for the subpartitioning expression that defines the subpartitioning for a table as **PARTITION_EXPRESSION** does for the partitioning expression used to define a table's partitioning.

If the table has no subpartitions, then this column is **NULL**.

- **PARTITION_DESCRIPTION**: This column is used for [RANGE](#) and [LIST](#) partitions. For a [RANGE](#) partition, it contains the value set in the partition's **VALUES LESS THAN** clause, which can be either an integer or [MAXVALUE](#). For a [LIST](#) partition, this column contains the values defined in the partition's **VALUES IN** clause, which is a comma-separated list of integer values.

For partitions whose **PARTITION_METHOD** is other than [RANGE](#) or [LIST](#), this column is always **NULL**.

- **TABLE_ROWS**: The number of table rows in the partition.
- **AVG_ROW_LENGTH**: The average length of the rows stored in this partition or subpartition, in bytes.

This is the same as **DATA_LENGTH** divided by **TABLE_ROWS**.

- **DATA_LENGTH**: The total length of all rows stored in this partition or subpartition, in bytes — that is, the total number of bytes stored in the partition or subpartition.
- **MAX_DATA_LENGTH**: The maximum number of bytes that can be stored in this partition or subpartition.
- **INDEX_LENGTH**: The length of the index file for this partition or subpartition, in bytes.
- **DATA_FREE**: The number of bytes allocated to the partition or subpartition but not used.
- **CREATE_TIME**: The time of the partition's or subpartition's creation.
- **UPDATE_TIME**: The time that the partition or subpartition was last modified.
- **CHECK_TIME**: The last time that the table to which this partition or subpartition belongs was checked.

Note

Some storage engines do not update this time; for tables using these storage engines, this value is always **NULL**.

- **CHECKSUM**: The checksum value, if any; otherwise, this column is `NULL`.
- **PARTITION_COMMENT**: This column contains the text of any comment made for the partition.

The default value for this column is an empty string.

- **NODEGROUP**: This is the nodegroup to which the partition belongs. This is relevant only to MySQL Cluster tables; otherwise the value of this column is always `0`.
- **TABLESPACE_NAME**: This column contains the name of tablespace to which the partition belongs. In MySQL 5.1, the value of this column is always `DEFAULT`.
-

Important

If any partitioned tables created in a MySQL version prior to MySQL 5.1.6 are present following an upgrade to MySQL 5.1.6 or later, it is not possible to `SELECT` from, `SHOW`, or `DESCRIBE` the `PARTITIONS` table. See [Section C.1.24, “Changes in release 5.1.6 \(01 February 2006\)”](#) before upgrading from MySQL 5.1.5 or earlier to MySQL 5.1.6 or later.

- A non-partitioned table has one record in `INFORMATION_SCHEMA.PARTITIONS`; however, the values of the `PARTITION_NAME`, `SUBPARTITION_NAME`, `PARTITION_ORDINAL_POSITION`, `SUBPARTITION_ORDINAL_POSITION`, `PARTITION_METHOD`, `SUBPARTITION_METHOD`, `PARTITION_EXPRESSION`, `SUBPARTITION_EXPRESSION`, and `PARTITION_DESCRIPTION` columns are all `NULL`. (The `PARTITION_COMMENT` column in this case is blank.)

In MySQL 5.1, there is also only one record in the `PARTITIONS` table for a table using the `NDBCluster` storage engine. The same columns are also `NULL` (or empty) as for a non-partitioned table.

23.20. The `INFORMATION_SCHEMA EVENTS` Table

The `EVENTS` table provides information about scheduled events, which are discussed in [Chapter 21, Event Scheduler](#).

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>EVENT_CATALOG</code>		<code>NULL</code> , MySQL extension
<code>EVENT_SCHEMA</code>	<code>Db</code>	MySQL extension
<code>EVENT_NAME</code>	<code>Name</code>	MySQL extension
<code>DEFINER</code>	<code>Definer</code>	MySQL extension
<code>TIME_ZONE</code>	<code>Time zone</code>	MySQL extension
<code>EVENT_BODY</code>		MySQL extension
<code>EVENT_DEFINITION</code>		MySQL extension
<code>EVENT_TYPE</code>	<code>Type</code>	MySQL extension
<code>EXECUTE_AT</code>	<code>Execute at</code>	MySQL extension
<code>INTERVAL_VALUE</code>	<code>Interval value</code>	MySQL extension
<code>INTERVAL_FIELD</code>	<code>Interval field</code>	MySQL extension
<code>SQL_MODE</code>		MySQL extension
<code>STARTS</code>	<code>Starts</code>	MySQL extension
<code>ENDS</code>	<code>Ends</code>	MySQL extension
<code>STATUS</code>	<code>Status</code>	MySQL extension
<code>ON_COMPLETION</code>		MySQL extension
<code>CREATED</code>		MySQL extension
<code>LAST_ALTERED</code>		MySQL extension
<code>LAST_EXECUTED</code>		MySQL extension
<code>EVENT_COMMENT</code>		MySQL extension
<code>ORIGINATOR</code>	<code>Originator</code>	MySQL extension
<code>CHARACTER_SET_CLIENT</code>		MySQL extension

COLLATION_CONNECTION		MySQL extension
DATABASE_COLLATION		MySQL extension

Notes:

- The **EVENTS** table is a non-standard table. It was added in MySQL 5.1.6.
- **EVENT_CATALOG**: The value of this column is always **NULL**.
- **EVENT_SCHEMA**: The name of the schema (database) to which this event belongs.
- **EVENT_NAME**: The name of the event.
- **DEFINER**: The user who created the event. Always displayed in '*user_name*'@'*host_name*' format.
- **TIME_ZONE**: The time zone in effect when schedule for the event was last modified. If the event's schedule has not been modified since the event was created, then this is the time zone that was in effect at the event's creation. The default value is **SYSTEM**.

This column was added in MySQL 5.1.17. See [Section C.1.10, “Changes in release 5.1.17 \(04 April 2007\)”](#), for important information if you are using the Event Scheduler and are upgrading from MySQL 5.1.16 (or earlier) to MySQL 5.1.17 (or later).

- **EVENT_BODY**: The language used for the statements in the event's **DO** clause; in MySQL 5.1, this is always **SQL**.

This column was added in MySQL 5.1.12. It is not to be confused with the column of the same name (now named **EVENT_DEFINITION**) that existed in earlier MySQL versions.

- **EVENT_DEFINITION**: The text of the SQL statement making up the event's **DO** clause; in other words, the statement executed by this event.

Note

Prior to MySQL 5.1.12, this column was named **EVENT_BODY**.

- **EVENT_TYPE**: One of the two values **ONE TIME** or **RECURRING**.
- **EXECUTE_AT**: For a one-time event, this is the **DATETIME** value specified in the **AT** clause of the **CREATE EVENT** statement used to create the event, or of the last **ALTER EVENT** statement that modified the event. The value shown in this column reflects the addition or subtraction of any **INTERVAL** value included in the event's **AT** clause. For example, if an event is created using **ON SCHEDULE AT CURRENT_TIMESTAMP + '1:6' DAY_HOUR**, and the event was created at 2006-02-09 14:05:30, the value shown in this column would be '**2006-02-10 20:05:30**'.

If the event's timing is determined by an **EVERY** clause instead of an **AT** clause (that is, if the event is recurring), the value of this column is **NULL**.

- **INTERVAL_VALUE**: For recurring events, this column contains the numeric portion of the event's **EVERY** clause.

For a one-time event (that is, an event whose timing is determined by an **AT** clause), this column's value is **NULL**.

- **INTERVAL_FIELD**: For recurring events, this column contains the units portion of the **EVERY** clause governing the timing of the event, prefixed with '**INTERVAL_**'. Thus, this column contains a value such as '**INTERVAL_YEAR**', '**INTERVAL_QUARTER**', '**INTERVAL_DAY**', and so on.

For a one-time event (that is, an event whose timing is determined by an **AT** clause), this column's value is **NULL**.

- **SQL_MODE**: The SQL mode in effect at the time the event was created or altered.
- **STARTS**: For a recurring event whose definition includes a **STARTS** clause, this column contains the corresponding **DATETIME** value. As with the **EXECUTE_AT** column, this value resolves any expressions used.

If there is no **STARTS** clause affecting the timing of the event, this column is empty. (Prior to MySQL 5.1.8, it contained **NULL** in such cases.)

- **ENDS**: For a recurring event whose definition includes a **ENDS** clause, this column contains the corresponding **DATETIME** value.

As with the `EXECUTE_AT` column (see previous example), this value resolves any expressions used.

If there is no `ENDS` clause affecting the timing of the event, this column contains `NULL`.

- **STATUS:** One of the three values `ENABLED`, `DISABLED`, or `SLAVESIDE_DISABLED`.

`SLAVESIDE_DISABLED` was added to the list of possible values for this column in MySQL 5.1.18. This value indicates that the creation of the event occurred on another MySQL server acting as a replication master and was replicated to the current MySQL server which is acting as a slave, but the event is not presently being executed on the slave. See [Section 15.3.1.5, “Replication of Invoked Features”](#), for more information.

- **ON_COMPLETION:** One of the two values `PRESERVE` or `NOT PRESERVE`.
- **CREATED:** The date and time when the event was created. This is a `DATETIME` value.
- **LAST_ALTERED:** The date and time when the event was last modified. This is a `DATETIME` value. If the event has not been modified since its creation, this column holds the same value as the `CREATED` column.
- **LAST_EXECUTED:** The date and time when the event last executed. A `DATETIME` value. If the event has never executed, this column's value is `NULL`.
- **EVENT_COMMENT:** The text of a comment, if the event has one. If there is no comment, the value of this column is an empty string.
- **ORIGINATOR:** The server ID of the MySQL server on which the event was created; used in replication. The default value is 0. This column was added in MySQL 5.1.18.
- **CHARACTER_SET_CLIENT** is the session value of the `character_set_client` system variable when the event was created. **COLLATION_CONNECTION** is the session value of the `collation_connection` system variable when the event was created. **DATABASE_COLLATION** is the collation of the database with which the event is associated. These columns were added in MySQL 5.1.21.

Example: Suppose the user `jon@ghidora` creates an event named `e_daily`, and then modifies it a few minutes later using an `ALTER EVENT` statement, as shown here:

```
DELIMITER |
CREATE EVENT e_daily
ON SCHEDULE EVERY 1 DAY
STARTS CURRENT_TIMESTAMP + INTERVAL 6 HOUR
DISABLE
COMMENT 'Saves total number of sessions and
        clears the table once per day.'
DO
BEGIN
    INSERT INTO site_activity.totals (when, total)
    SELECT CURRENT_TIMESTAMP, COUNT(*)
    FROM site_activity.sessions;
    DELETE FROM site_activity.sessions;
END |
DELIMITER ;
ALTER EVENT e_daily
ENABLED;
```

(Note that comments can span multiple lines.)

This user can then run the following `SELECT` statement, and obtain the output shown:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
> WHERE EVENT_NAME = 'e_daily'
> AND EVENT_SCHEMA = 'myschema'\G
***** 1. row *****
EVENT_CATALOG: NULL
EVENT_SCHEMA: myschema
EVENT_NAME: e_daily
DEFINER: jon@ghidora
EVENT_BODY: BEGIN
    INSERT INTO site_activity.totals (when, total)
    SELECT CURRENT_TIMESTAMP, COUNT(*)
    FROM site_activity.sessions;
    DELETE FROM site_activity.sessions;
END
```

```

EVENT_TYPE: RECURRING
EXECUTE_AT: NULL
INTERVAL_VALUE: 1
INTERVAL_FIELD: INTERVAL_DAY
SQL_MODE: NULL
STARTS: 2006-02-09 10:41:23
ENDS: NULL
STATUS: ENABLED
ON_COMPLETION: DROP
CREATED: 2006-02-09 14:35:35
LAST_ALTERED: 2006-02-09 14:41:23
LAST_EXECUTED: NULL
EVENT_COMMENT: Saves total number of sessions and
                clears the table once per day.
ORIGINATOR: 0
1 row in set (0.50 sec)

```

Prior to MySQL 5.1.17, the times displayed in the `STARTS`, `ENDS`, and `LAST_EXECUTED` columns were given in terms of Universal Time (GMT or UTC), regardless of the server's time zone setting ([Bug#16420](#)). Beginning with MySQL 5.1.17, these times are all given in terms of local time as determined by the MySQL server's `time_zone` setting. (The same was true of the `starts`, `ends`, and `last_executed` columns of the `mysql.event` table as well as the `Starts` and `Ends` columns in the output of `SHOW [FULL] EVENTS`.)

The `CREATED` and `LAST_ALTERED` columns use the server time zone (as do the `created` and `last_altered` columns of the `mysql.event` table).

See also [Section 12.5.4.16](#), “`SHOW EVENTS`”.

23.21. The `INFORMATION_SCHEMA FILES` Table

The `FILES` table provides information about the files in which MySQL `NDB` Disk Data tables are stored.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>FILE_ID</code>		MySQL extension
<code>FILE_NAME</code>		MySQL extension
<code>FILE_TYPE</code>		MySQL extension
<code>TABLESPACE_NAME</code>		MySQL extension
<code>TABLE_CATALOG</code>		MySQL extension
<code>TABLE_SCHEMA</code>		MySQL extension
<code>TABLE_NAME</code>		MySQL extension
<code>LOGFILE_GROUP_NAME</code>		MySQL extension
<code>LOGFILE_GROUP_NUMBER</code>		MySQL extension
<code>ENGINE</code>		MySQL extension
<code>FULLTEXT_KEYS</code>		MySQL extension
<code>DELETED_ROWS</code>		MySQL extension
<code>UPDATE_COUNT</code>		MySQL extension
<code>FREE_EXTENTS</code>		MySQL extension
<code>TOTAL_EXTENTS</code>		MySQL extension
<code>EXTENT_SIZE</code>		MySQL extension
<code>INITIAL_SIZE</code>		MySQL extension
<code>MAXIMUM_SIZE</code>		MySQL extension
<code>AUTOEXTEND_SIZE</code>		MySQL extension
<code>CREATION_TIME</code>		MySQL extension
<code>LAST_UPDATE_TIME</code>		MySQL extension
<code>LAST_ACCESS_TIME</code>		MySQL extension
<code>RECOVER_TIME</code>		MySQL extension
<code>TRANSACTION_COUNTER</code>		MySQL extension

VERSION		MySQL extension
ROW_FORMAT		MySQL extension
TABLE_ROWS		MySQL extension
AVG_ROW_LENGTH		MySQL extension
DATA_LENGTH		MySQL extension
MAX_DATA_LENGTH		MySQL extension
INDEX_LENGTH		MySQL extension
DATA_FREE		MySQL extension
CREATE_TIME		MySQL extension
UPDATE_TIME		MySQL extension
CHECK_TIME		MySQL extension
CHECKSUM		MySQL extension
STATUS		MySQL extension
EXTRA		MySQL extension

Notes:

- **FILE_ID** column values are auto-generated.
- **FILE_NAME** is the name of an **UNDO** log file created by **CREATE LOGFILE GROUP** or **ALTER LOGFILE GROUP**, or of a data file created by **CREATE TABLESPACE** or **ALTER TABLESPACE**.
- **FILE_TYPE** is one of the values **UNDOFILE** or **DATAFILE**.
- **TABLESPACE_NAME** is the name of the tablespace with which the file is associated.
- In MySQL 5.1, the value of the **TABLESPACE_CATALOG** column is always **NULL**.
- **TABLE_NAME** is the name of the Disk Data table with which the file is associated, if any.
- The **LOGFILE_GROUP_NAME** column gives the name of the log file group to which the log file or data file belongs.
- For an **UNDO** log file, the **LOGFILE_GROUP_NUMBER** contains the auto-generated ID number of the log file group to which the log file belongs.
- For a MySQL Cluster Disk Data log file or data file, the value of the **ENGINE** column is always **NDB** or **NDBCLUSTER**.
- For a MySQL Cluster Disk Data log file or data file, the value of the **FULLTEXT_KEYS** column is always empty.
- The **FREE_EXTENTS** column displays the number of extents which have not yet been used by the file. The **TOTAL_EXTENTS** column show the total number of extents allocated to the file.

The difference between these two columns is the number of extents currently in use by the file:

```
SELECT TOTAL_EXTENTS - FREE_EXTENTS AS extents_used
FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME = 'myfile.dat';
```

You can approximate the amount of disk space in use by the file by multiplying this difference by the value of the **EXTENT_SIZE** column, which gives the size of an extent for the file in bytes:

```
SELECT (TOTAL_EXTENTS - FREE_EXTENTS) * EXTENT_SIZE AS bytes_used
FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME = 'myfile.dat';
```

Similarly, you can estimate the amount of space that remains available in a given file by multiplying **FREE_EXTENTS** by **EXTENT_SIZE**:

```
SELECT FREE_EXTENTS * EXTENT_SIZE AS bytes_free
FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME = 'myfile.dat';
```

Important

The byte values produced by the preceding queries are approximations only, and their precision is inversely proportional to the value of `EXTENT_SIZE`. That is, the larger `EXTENT_SIZE` becomes, the less accurate the approximations are.

It is also important to remember that once an extent is used, it cannot be freed again without dropping the data file of which it is a part. This means that deletes from a Disk Data table do *not* release disk space.

The extent size can be set in a `CREATE TABLESPACE` statement. See [Section 12.1.11, “CREATE TABLESPACE Syntax”](#), for more information.

- The `INITIAL_SIZE` column shows the size in bytes of the file. This is the same value that was used in the `INITIAL_SIZE` clause of the `CREATE LOGFILE GROUP`, `ALTER LOGFILE GROUP`, `CREATE TABLESPACE`, or `ALTER TABLESPACE` statement used to create the file.

For MySQL 5.1 Cluster Disk Data files, the value of the `MAXIMUM_SIZE` column is always the same as `INITIAL_SIZE`, and the `AUTOEXTEND_SIZE` column is always empty.

- The `CREATION_TIME` column shows the date and time when the file was created. The `LAST_UPDATE_TIME` column displays the date and time when the file was last modified. The `LAST_ACCESSED` column provides the date and time when the file was last accessed by the server.

Currently, the values of these columns are as reported by the operating system, and are not supplied by the NDB storage engine. Where no value is provided by the operating system, these columns display `0000-00-00 00:00:00`.

- For MySQL Cluster Disk Data files, the value of the `RECOVER_TIME` and `TRANSACTION_COUNTER` columns is always 0.
- For MySQL 5.1 Cluster Disk Data files, the following columns are always `NULL`:
 - `VERSION`
 - `ROW_FORMAT`
 - `TABLE_ROWS`
 - `AVG_ROW_LENGTH`
 - `DATA_LENGTH`
 - `MAX_DATA_LENGTH`
 - `INDEX_LENGTH`
 - `DATA_FREE`
 - `CREATE_TIME`
 - `UPDATE_TIME`
 - `CHECK_TIME`
 - `CHECKSUM`
- For MySQL Cluster Disk Data files, the value of the `STATUS` column is always `NORMAL`.
- For MySQL Cluster Disk Data files, the `EXTRA` column shows which data node the file belongs to, as each data node has its own copy of the file. For example, suppose you use this statement on a MySQL Cluster with four data nodes:

```
CREATE LOGFILE GROUP mygroup
ADD UNDOFILE 'new_undo.dat'
INITIAL_SIZE 2G
ENGINE NDB;
```

After running the `CREATE LOGFILE GROUP` statement successfully, you should see a result similar to the one shown here for this query against the `FILES` table:

```
mysql> SELECT LOGFILE_GROUP_NAME, FILE_TYPE, EXTRA
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE FILE_NAME = 'new_undo.dat';
```

LOGFILE_GROUP_NAME	FILE_TYPE	EXTRA
mygroup	UNDO FILE	CLUSTER_NODE=3
mygroup	UNDO FILE	CLUSTER_NODE=4
mygroup	UNDO FILE	CLUSTER_NODE=5
mygroup	UNDO FILE	CLUSTER_NODE=6

4 rows in set (0.01 sec)

- The `FILES` table is a non-standard table. It was added in MySQL 5.1.6.
- Beginning with MySQL 5.1.14, an additional row is present in the `FILES` table following the creation of a logfile group. This row has `NULL` for the value of the `FILE_NAME` column. For this row, the value of the `FILE_ID` column is always `0`, that of the `FILE_TYPE` column is always `UNDO FILE`, and that of the `STATUS` column is always `NORMAL`. In MySQL 5.1 the value of the `ENGINE` column is always `ndbcluster`.

This row shows in the `FREE_EXTENTS` column the total number of free extents available to all undo files belonging to a given log file group whose name and number are shown in the `LOGFILE_GROUP_NAME` and `LOGFILE_GROUP_NUMBER` columns, respectively.

Suppose there are no existing log file groups on your MySQL Cluster, and you create one using the following statement:

```
mysql> CREATE LOGFILE GROUP lg1
-> ADD UNDOFILE 'undofile.dat'
-> INITIAL_SIZE = 16M
-> UNDO_BUFFER_SIZE = 1M
-> ENGINE = NDB;
```

Query OK, 0 rows affected (3.81 sec)

You can now see this `NULL` row when you query the `FILES` table:

```
mysql> SELECT DISTINCT
-> FILE_NAME AS File,
-> FREE_EXTENTS AS Free,
-> TOTAL_EXTENTS AS Total,
-> EXTENT_SIZE AS Size,
-> INITIAL_SIZE AS Initial
-> FROM INFORMATION_SCHEMA.FILES;
```

File	Free	Total	Size	Initial
undofile.dat	NULL	4194304	4	16777216
NULL	4184068	NULL	4	NULL

2 rows in set (0.01 sec)

The total number of free extents available for undo logging is always somewhat less than the sum of the `TOTAL_EXTENTS` column values for all undo files in the log file group due to overhead required for maintaining the undo files. This can be seen by adding a second undo file to the log file group, then repeating the previous query against the `FILES` table:

```
mysql> ALTER LOGFILE GROUP lg1
-> ADD UNDOFILE 'undofile02.dat'
-> INITIAL_SIZE = 4M
-> ENGINE = NDB;
```

Query OK, 0 rows affected (1.02 sec)

```
mysql> SELECT DISTINCT
-> FILE_NAME AS File,
-> FREE_EXTENTS AS Free,
-> TOTAL_EXTENTS AS Total,
-> EXTENT_SIZE AS Size,
-> INITIAL_SIZE AS Initial
-> FROM INFORMATION_SCHEMA.FILES;
```

File	Free	Total	Size	Initial
undofile.dat	NULL	4194304	4	16777216
undofile02.dat	NULL	1048576	4	4194304
NULL	5223944	NULL	4	NULL

```
3 rows in set (0.01 sec)
```

The amount of free space in bytes which is available for undo logging by Disk Data tables using this log file group can be approximated by multiplying the number of free extents by the initial size:

```
mysql> SELECT
->   FREE_EXTENTS AS 'Free Extents',
->   FREE_EXTENTS * EXTENT_SIZE AS 'Free Bytes'
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE LOGFILE_GROUP_NAME = 'lg1'
-> AND FILE_NAME IS NULL;
+-----+-----+
| Free Extents | Free Bytes |
+-----+-----+
|      5223944 |  20895776 |
+-----+-----+
1 row in set (0.02 sec)
```

If you create a Disk Data table and then insert some rows into it, you can see approximately how much space remains for undo logging afterwards, for example:

```
mysql> CREATE TABLESPACE ts1
->   ADD DATAFILE 'data1.dat'
->   USE LOGFILE GROUP lg1
->   INITIAL_SIZE 512M
->   ENGINE = NDB;
Query OK, 0 rows affected (8.71 sec)

mysql> CREATE TABLE dd (
->   c1 INT NOT NULL PRIMARY KEY,
->   c2 INT,
->   c3 DATE
-> )
-> TABLESPACE ts1 STORAGE DISK
-> ENGINE = NDB;
Query OK, 0 rows affected (2.11 sec)

mysql> INSERT INTO dd VALUES
->   (NULL, 1234567890, '2007-02-02'),
->   (NULL, 1126789005, '2007-02-03'),
->   (NULL, 1357924680, '2007-02-04'),
->   (NULL, 1642097531, '2007-02-05');
Query OK, 4 rows affected (0.01 sec)

mysql> SELECT
->   FREE_EXTENTS AS 'Free Extents',
->   FREE_EXTENTS * EXTENT_SIZE AS 'Free Bytes'
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE LOGFILE_GROUP_NAME = 'lg1'
-> AND FILE_NAME IS NULL;
+-----+-----+
| Free Extents | Free Bytes |
+-----+-----+
|      5207565 |  20830260 |
+-----+-----+
1 row in set (0.01 sec)
```

- There are no `SHOW` commands associated with the `FILES` table.
- For additional examples using the `FILES` table to obtain information about Cluster Disk Data tables, see [Section 16.11, “MySQL Cluster Disk Data Tables”](#).

23.22. The INFORMATION_SCHEMA PROCESSLIST Table

The `PROCESSLIST` table provides information about which threads are running.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
ID	Id	MySQL extension
USER	User	MySQL extension
HOST	Host	MySQL extension
DB	db	MySQL extension
COMMAND	Command	MySQL extension

<code>TIME</code>	<code>Time</code>	MySQL extension
<code>STATE</code>	<code>State</code>	MySQL extension
<code>INFO</code>	<code>Info</code>	MySQL extension

For an extensive description of the table columns, see [Section 12.5.4.25, “SHOW PROCESSLIST Syntax”](#).

Notes:

- The `PROCESSLIST` table is a non-standard table. It was added in MySQL 5.1.7.
- Like the output from the corresponding `SHOW` statement, the `PROCESSLIST` table will only show information about your own threads, unless you have the `PROCESS` privilege, in which case you will see information about other threads, too. As an anonymous user, you cannot see any rows at all.
- If an SQL statement refers to `INFORMATION_SCHEMA.PROCESSLIST`, then MySQL will populate the entire table once, when statement execution begins, so there is read consistency during the statement. There is no read consistency for a multi-statement transaction, though.

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST
SHOW FULL PROCESSLIST
```

23.23. The `INFORMATION_SCHEMA REFERENTIAL_CONSTRAINTS` Table

The `REFERENTIAL_CONSTRAINTS` table provides information about foreign keys.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>CONSTRAINT_CATALOG</code>		NULL
<code>CONSTRAINT_SCHEMA</code>		
<code>CONSTRAINT_NAME</code>		
<code>UNIQUE_CONSTRAINT_CATALOG</code>		NULL
<code>UNIQUE_CONSTRAINT_SCHEMA</code>		
<code>UNIQUE_CONSTRAINT_NAME</code>		
<code>MATCH_OPTION</code>		
<code>UPDATE_RULE</code>		
<code>DELETE_RULE</code>		
<code>TABLE_NAME</code>		
<code>REFERENCED_TABLE_NAME</code>		

Notes:

- The `REFERENTIAL_CONSTRAINTS` table was added in MySQL 5.1.10. The `REFERENCED_TABLE_NAME` column was added in MySQL 5.1.16.
- `TABLE_NAME` has the same value as `TABLE_NAME` in `INFORMATION_SCHEMA.TABLE_CONSTRAINTS`.
- `CONSTRAINT_SCHEMA` and `CONSTRAINT_NAME` identify the foreign key.
- `UNIQUE_CONSTRAINT_SCHEMA`, `UNIQUE_CONSTRAINT_NAME`, and `REFERENCED_TABLE_NAME` identify the referenced key. (Note: Before MySQL 5.1.16, `UNIQUE_CONSTRAINT_NAME` incorrectly named the referenced table, not the constraint.)
- The only valid value at this time for `MATCH_OPTION` is `NONE`.

- The possible values for `UPDATE_RULE` or `DELETE_RULE` are `CASCADE`, `SET NULL`, `SET DEFAULT`, `RESTRICT`, `NO ACTION`.

23.24. The `INFORMATION_SCHEMA GLOBAL_STATUS` and `SESSION_STATUS` Tables

The `GLOBAL_STATUS` and `SESSION_STATUS` tables provide information about server status variables. Their contents correspond to the information produced by the `SHOW GLOBAL STATUS` and `SHOW SESSION STATUS` statements (see [Section 12.5.4.27](#), “`SHOW STATUS Syntax`”).

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>VARIABLE_NAME</code>	<code>Variable_name</code>	
<code>VARIABLE_VALUE</code>	Value	

Notes:

- The `GLOBAL_STATUS` and `SESSION_STATUS` tables were added in MySQL 5.1.12.
- Beginning with MySQL 5.1.19, the `VARIABLE_VALUE` column for each of these tables is defined as `VARCHAR(20480)`. Previously, this column had the data type `DECIMAL(22, 7)`, but was changed to avoid loss of data when working with status variables whose values were strings ([Bug#26994](#)).

23.25. The `INFORMATION_SCHEMA GLOBAL_VARIABLES` and `SESSION_VARIABLES` Tables

The `GLOBAL_VARIABLES` and `SESSION_VARIABLES` tables provide information about server status variables. Their contents correspond to the information produced by the `SHOW GLOBAL VARIABLES` and `SHOW SESSION VARIABLES` statements (see [Section 12.5.4.31](#), “`SHOW VARIABLES Syntax`”).

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>VARIABLE_NAME</code>	<code>Variable_name</code>	
<code>VARIABLE_VALUE</code>	Value	

Notes:

- The `GLOBAL_VARIABLES` and `SESSION_VARIABLES` tables were added in MySQL 5.1.12.
- Beginning with MySQL 5.1.19, the `VARIABLE_VALUE` column for each of these tables is defined as `VARCHAR(20480)`. Previously, this column had the data type `LONGTEXT`; this was changed in order to make these tables consistent with the `GLOBAL_STATUS` and `SESSION_STATUS` tables, whose definitions had been changed in that version (see [Section 23.24](#), “[The INFORMATION_SCHEMA GLOBAL_STATUS and SESSION_STATUS Tables](#)”).

23.26. Other `INFORMATION_SCHEMA` Tables

We intend to implement additional `INFORMATION_SCHEMA` tables. In particular, we acknowledge the need for the `PARAMETERS` table.

23.27. Extensions to `SHOW` Statements

Some extensions to `SHOW` statements accompany the implementation of `INFORMATION_SCHEMA`:

- **SHOW** can be used to get information about the structure of **INFORMATION_SCHEMA** itself.
- Several **SHOW** statements accept a **WHERE** clause that provides more flexibility in specifying which rows to display.

INFORMATION_SCHEMA is an information database, so its name is included in the output from **SHOW DATABASES**. Similarly, **SHOW TABLES** can be used with **INFORMATION_SCHEMA** to obtain a list of its tables:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA;
+-----+
| Tables_in_INFORMATION_SCHEMA |
+-----+
| CHARACTER_SETS                |
| COLLATIONS                    |
| COLLATION_CHARACTER_SET_APPLICABILITY |
| COLUMNS                      |
| COLUMN_PRIVILEGES             |
| ENGINES                       |
| EVENTS                       |
| FILES                         |
| GLOBAL_STATUS                 |
| GLOBAL_VARIABLES              |
| KEY_COLUMN_USAGE              |
| PARTITIONS                    |
| PLUGINS                       |
| PROCESSLIST                   |
| REFERENTIAL_CONSTRAINTS       |
| ROUTINES                      |
| SCHEMATA                      |
| SCHEMA_PRIVILEGES             |
| SESSION_STATUS                |
| SESSION_VARIABLES             |
| STATISTICS                    |
| TABLES                       |
| TABLE_CONSTRAINTS            |
| TABLE_PRIVILEGES             |
| TRIGGERS                      |
| USER_PRIVILEGES               |
| VIEWS                         |
+-----+
27 rows in set (0.00 sec)
```

SHOW COLUMNS and **DESCRIBE** can display information about the columns in individual **INFORMATION_SCHEMA** tables.

SHOW statements that accept a **LIKE** clause to limit the rows displayed also allow a **WHERE** clause that enables specification of more general conditions that selected rows must satisfy:

```
SHOW CHARACTER SET
SHOW COLLATION
SHOW COLUMNS
SHOW DATABASES
SHOW FUNCTION STATUS
SHOW INDEX
SHOW OPEN TABLES
SHOW PROCEDURE STATUS
SHOW STATUS
SHOW TABLE STATUS
SHOW TABLES
SHOW TRIGGERS
SHOW VARIABLES
```

The **WHERE** clause, if present, is evaluated against the column names displayed by the **SHOW** statement. For example, the **SHOW CHARACTER SET** statement produces these output columns:

```
mysql> SHOW CHARACTER SET;
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
| big5    | Big5 Traditional Chinese | big5_chinese_ci | 2 |
| dec8    | DEC West European | dec8_swedish_ci | 1 |
| cp850   | DOS West European | cp850_general_ci | 1 |
| hp8     | HP West European | hp8_english_ci | 1 |
| koi8r   | KOI8-R Relcom Russian | koi8r_general_ci | 1 |
| latin1  | cp1252 West European | latin1_swedish_ci | 1 |
| latin2  | ISO 8859-2 Central European | latin2_general_ci | 1 |
| ...     | ... | ... | ... |
```

To use a **WHERE** clause with **SHOW CHARACTER SET**, you would refer to those column names. As an example, the following statement displays information about character sets for which the default collation contains the string **'japanese'**:

```
mysql> SHOW CHARACTER SET WHERE `Default collation` LIKE '%japanese%';
```

Charset	Description	Default collation	Maxlen
ujis	EUC-JP Japanese	ujis_japanese_ci	3
sjis	Shift-JIS Japanese	sjis_japanese_ci	2
cp932	SJIS for Windows Japanese	cp932_japanese_ci	2

Chapter 24. Precision Math

MySQL 5.1 provides support for precision math: numeric value handling that results in extremely accurate results and a high degree control over invalid values. Precision math is based on these two features:

- SQL modes that control how strict the server is about accepting or rejecting invalid data.
- The MySQL library for fixed-point arithmetic.

These features have several implications for numeric operations:

- **Precise calculations:** For exact-value numbers, calculations do not introduce floating-point errors. Instead, exact precision is used. For example, a number such as `.0001` is treated as an exact value rather than as an approximation, and summing it 10,000 times produces a result of exactly `1`, not a value that merely “close” to 1.
- **Well-defined rounding behavior:** For exact-value numbers, the result of `ROUND()` depends on its argument, not on environmental factors such as how the underlying C library works.
- **Platform independence:** Operations on exact numeric values are the same across different platforms such as Windows and Unix.
- **Control over handling of invalid values:** Overflow and division by zero are detectable and can be treated as errors. For example, you can treat a value that is too large for a column as an error rather than having the value truncated to lie within the range of the column's data type. Similarly, you can treat division by zero as an error rather than as an operation that produces a result of `NULL`. The choice of which approach to take is determined by the setting of the `sql_mode` system variable.

An important result of these features is that MySQL 5.1 provides a high degree of compliance with standard SQL.

The following discussion covers several aspects of how precision math works (including possible incompatibilities with older applications). At the end, some examples are given that demonstrate how MySQL 5.1 handles numeric operations precisely. For information about using the `sql_mode` system variable to control the SQL mode, see [Section 5.2.6, “SQL Modes”](#).

24.1. Types of Numeric Values

The scope of precision math for exact-value operations includes the exact-value data types (`DECIMAL` and integer types) and exact-value numeric literals. Approximate-value data types and numeric literals still are handled as floating-point numbers.

Exact-value numeric literals have an integer part or fractional part, or both. They may be signed. Examples: `1`, `.2`, `3.4`, `-5`, `-6.78`, `+9.10`.

Approximate-value numeric literals are represented in scientific notation with a mantissa and exponent. Either or both parts may be signed. Examples: `1.2E3`, `1.2E-3`, `-1.2E3`, `-1.2E-3`.

Two numbers that look similar need not be both exact-value or both approximate-value. For example, `2.34` is an exact-value (fixed-point) number, whereas `2.34E0` is an approximate-value (floating-point) number.

The `DECIMAL` data type is a fixed-point type and calculations are exact. In MySQL, the `DECIMAL` type has several synonyms: `NUMERIC`, `DEC`, `FIXED`. The integer types also are exact-value types.

The `FLOAT` and `DOUBLE` data types are floating-point types and calculations are approximate. In MySQL, types that are synonymous with `FLOAT` or `DOUBLE` are `DOUBLE PRECISION` and `REAL`.

24.2. `DECIMAL` Data Type Changes

This section discusses the characteristics of the `DECIMAL` data type (and its synonyms) in MySQL 5.1, with particular regard to the following topics:

- Maximum number of digits
- Storage format

- Storage requirements
- The non-standard MySQL extension to the upper range of **DECIMAL** columns

Possible incompatibilities with applications that are written for older versions of MySQL are noted throughout this section.

The declaration syntax for a **DECIMAL** column is **DECIMAL**(*M*, *D*). The ranges of values for the arguments in MySQL 5.1 are as follows:

- *M* is the maximum number of digits (the precision). It has a range of 1 to 65. (Older versions of MySQL allowed a range of 1 to 254.)
- *D* is the number of digits to the right of the decimal point (the scale). It has a range of 0 to 30 and must be no larger than *M*.

The maximum value of 65 for *M* means that calculations on **DECIMAL** values are accurate up to 65 digits. This limit of 65 digits of precision also applies to exact-value numeric literals, so the maximum range of such literals is different from before. (In older versions of MySQL, decimal values could have up to 254 digits. However, calculations were done using floating-point and thus were approximate, not exact.)

Values for **DECIMAL** columns in MySQL 5.1 are stored using a binary format that packs nine decimal digits into four bytes. The storage requirements for the integer and fractional parts of each value are determined separately. Each multiple of nine digits requires four bytes, and any digits left over require some fraction of four bytes. For example, a **DECIMAL**(18, 9) column has nine digits on either side of the decimal point, so the integer part and the fractional part each require four bytes. A **DECIMAL**(20, 10) column has ten digits on either side of the decimal point. Each part requires four bytes for nine of the digits, and one byte for the remaining digit.

The storage required for leftover digits is given by the following table:

Leftover Digits	Number of Bytes
0	0
1	1
2	1
3	2
4	2
5	3
6	3
7	4
8	4
9	4

Unlike some older versions of MySQL (prior to 5.0.3), **DECIMAL** columns in MySQL 5.1 do not store a leading + character or leading 0 digits. If you insert +0003.1 into a **DECIMAL**(5, 1) column, it is stored as 3.1. Applications that rely on the older behavior must be modified to account for this change.

DECIMAL columns in MySQL 5.1 do not allow values larger than the range implied by the column definition. For example, a **DECIMAL**(3, 0) column supports a range of -999 to 999. A **DECIMAL**(*M*, *D*) column allows at most *M* - *D* digits to the left of the decimal point. This is not compatible with applications relying on older versions of MySQL that allowed storing an extra digit in lieu of a + sign.

The SQL standard requires that the precision of **NUMERIC**(*M*, *D*) be exactly *M* digits. For **DECIMAL**(*M*, *D*), the standard requires a precision of at least *M* digits but allows more. In MySQL, **DECIMAL**(*M*, *D*) and **NUMERIC**(*M*, *D*) are the same, and both have a precision of exactly *M* digits.

For more detailed information about porting applications that rely on the old treatment of the **DECIMAL** data type, see the *MySQL 5.0 Reference Manual*.

24.3. Expression Handling

With precision math, exact-value numbers are used as given whenever possible. For example, numbers in comparisons are used exactly as given without a change in value. In strict SQL mode, for [INSERT](#) into a column with an exact data type ([DECIMAL](#) or integer), a number is inserted with its exact value if it is within the column range. When retrieved, the value should be the same as what was inserted. (Without strict mode, truncation for [INSERT](#) is allowable.)

Handling of a numeric expression depends on what kind of values the expression contains:

- If any approximate values are present, the expression is approximate and is evaluated using floating-point arithmetic.
- If no approximate values are present, the expression contains only exact values. If any exact value contains a fractional part (a value following the decimal point), the expression is evaluated using [DECIMAL](#) exact arithmetic and has a precision of 65 digits. (The term “exact” is subject to the limits of what can be represented in binary. For example, $1.0/3.0$ can be approximated in decimal notation as $.333\dots$, but not written as an exact number, so $(1.0/3.0)*3.0$ does not evaluate to exactly 1.0 .)
- Otherwise, the expression contains only integer values. The expression is exact and is evaluated using integer arithmetic and has a precision the same as [BIGINT](#) (64 bits).

If a numeric expression contains any strings, they are converted to double-precision floating-point values and the expression is approximate.

Inserts into numeric columns are affected by the SQL mode, which is controlled by the `sql_mode` system variable. (See [Section 5.2.6, “SQL Modes”](#).) The following discussion mentions strict mode (selected by the `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` mode values) and `ERROR_FOR_DIVISION_BY_ZERO`. To turn on all restrictions, you can simply use `TRADITIONAL` mode, which includes both strict mode values and `ERROR_FOR_DIVISION_BY_ZERO`:

```
mysql> SET sql_mode='TRADITIONAL';
```

If a number is inserted into an exact type column ([DECIMAL](#) or integer), it is inserted with its exact value if it is within the column range.

If the value has too many digits in the fractional part, rounding occurs and a warning is generated. Rounding is done as described in [Section 24.4, “Rounding Behavior”](#).

If the value has too many digits in the integer part, it is too large and is handled as follows:

- If strict mode is not enabled, the value is truncated to the nearest legal value and a warning is generated.
- If strict mode is enabled, an overflow error occurs.

Underflow is not detected, so underflow handling is undefined.

By default, division by zero produces a result of [NULL](#) and no warning. With the `ERROR_FOR_DIVISION_BY_ZERO` SQL mode enabled, MySQL handles division by zero differently:

- If strict mode is not enabled, a warning occurs.
- If strict mode is enabled, inserts and updates involving division by zero are prohibited, and an error occurs.

In other words, inserts and updates involving expressions that perform division by zero can be treated as errors, but this requires `ERROR_FOR_DIVISION_BY_ZERO` in addition to strict mode.

Suppose that we have this statement:

```
INSERT INTO t SET i = 1/0;
```

This is what happens for combinations of strict and `ERROR_FOR_DIVISION_BY_ZERO` modes:

<code>sql_mode</code> Value	Result
' ' (Default)	No warning, no error; <code>i</code> is set to NULL .

strict	No warning, no error; <code>i</code> is set to <code>NULL</code> .
<code>ERROR_FOR_DIVISION_BY_ZERO</code>	Warning, no error; <code>i</code> is set to <code>NULL</code> .
strict, <code>ERROR_FOR_DIVISION_BY_ZERO</code>	Error condition; no row is inserted.

For inserts of strings into numeric columns, conversion from string to number is handled as follows if the string has non-numeric contents:

- A string that does not begin with a number cannot be used as a number and produces an error in strict mode, or a warning otherwise. *This includes the empty string.*
- A string that begins with a number can be converted, but the trailing non-numeric portion is truncated. If the truncated portion contains anything other than spaces, this produces an error in strict mode, or a warning otherwise.

24.4. Rounding Behavior

This section discusses precision math rounding for the `ROUND()` function and for inserts into columns with exact-value types (`DECIMAL` and integer).

The `ROUND()` function rounds differently depending on whether its argument is exact or approximate:

- For exact-value numbers, `ROUND()` uses the “round half up” rule: A value with a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negative. (In other words, it is rounded away from zero.) A value with a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative.
- For approximate-value numbers, the result depends on the C library. On many systems, this means that `ROUND()` uses the “round to nearest even” rule: A value with any fractional part is rounded to the nearest even integer.

The following example shows how rounding differs for exact and approximate values:

```
mysql> SELECT ROUND(2.5), ROUND(25E-1);
+-----+-----+
| ROUND(2.5) | ROUND(25E-1) |
+-----+-----+
| 3          | 2            |
+-----+-----+
```

For inserts into a `DECIMAL` or integer column, the target is an exact data type, so rounding uses “round half up,” regardless of whether the value to be inserted is exact or approximate:

```
mysql> CREATE TABLE t (d DECIMAL(10,0));
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t VALUES(2.5),(2.5E0);
Query OK, 2 rows affected, 2 warnings (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 2

mysql> SELECT d FROM t;
+-----+
| d    |
+-----+
| 3    |
| 3    |
+-----+
```

24.5. Precision Math Examples

This section provides some examples that show precision math query results in MySQL 5.1.

Example 1. Numbers are used with their exact value as given when possible:

```
mysql> SELECT .1 + .2 = .3;
+-----+
| .1 + .2 = .3 |
+-----+
```

```
+-----+
|          1 |
+-----+
```

For floating-point values, results are inexact:

```
mysql> SELECT .1E0 + .2E0 = .3E0;
+-----+
| .1E0 + .2E0 = .3E0 |
+-----+
|                      0 |
+-----+
```

Another way to see the difference in exact and approximate value handling is to add a small number to a sum many times. Consider the following stored procedure, which adds `.0001` to a variable 1,000 times.

```
CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 0;
  DECLARE d DECIMAL(10,4) DEFAULT 0;
  DECLARE f FLOAT DEFAULT 0;
  WHILE i < 10000 DO
    SET d = d + .0001;
    SET f = f + .0001E0;
    SET i = i + 1;
  END WHILE;
  SELECT d, f;
END;
```

The sum for both `d` and `f` logically should be 1, but that is true only for the decimal calculation. The floating-point calculation introduces small errors:

```
+-----+-----+
| d       | f       |
+-----+-----+
| 1.0000  | 0.999999999999991 |
+-----+-----+
```

Example 2. Multiplication is performed with the scale required by standard SQL. That is, for two numbers `X1` and `X2` that have scale `S1` and `S2`, the scale of the result is `S1 + S2`:

```
mysql> SELECT .01 * .01;
+-----+
| .01 * .01 |
+-----+
| 0.0001    |
+-----+
```

Example 3. Rounding behavior is well-defined:

Rounding behavior (for example, with the `ROUND()` function) is independent of the implementation of the underlying C library, which means that results are consistent from platform to platform.

Rounding for exact-value columns (`DECIMAL` and integer) and exact-valued numbers uses the “round half up” rule. Values with a fractional part of .5 or greater are rounded away from zero to the nearest integer, as shown here:

```
mysql> SELECT ROUND(2.5), ROUND(-2.5);
+-----+-----+
| ROUND(2.5) | ROUND(-2.5) |
+-----+-----+
| 3          | -3          |
+-----+-----+
```

However, rounding for floating-point values uses the C library, which on many systems uses the “round to nearest even” rule. Values with any fractional part on such systems are rounded to the nearest even integer:

```
mysql> SELECT ROUND(2.5E0), ROUND(-2.5E0);
+-----+-----+
| ROUND(2.5E0) | ROUND(-2.5E0) |
+-----+-----+
| 2            | -2            |
+-----+-----+
```

Example 4. In strict mode, inserting a value that is too large results in overflow and causes an error, rather than truncation to a legal value.

When MySQL is not running in strict mode, truncation to a legal value occurs:

```
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t SET i = 128;
Query OK, 1 row affected, 1 warning (0.00 sec)

mysql> SELECT i FROM t;
+-----+
| i     |
+-----+
| 127   |
+-----+
1 row in set (0.00 sec)
```

However, an overflow condition occurs if strict mode is in effect:

```
mysql> SET sql_mode='STRICT_ALL_TABLES';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 128;
ERROR 1264 (22003): Out of range value adjusted for column 'i' at row 1

mysql> SELECT i FROM t;
Empty set (0.00 sec)
```

Example 5: In strict mode and with `ERROR_FOR_DIVISION_BY_ZERO` set, division by zero causes an error, and not a result of `NULL`.

In non-strict mode, division by zero has a result of `NULL`:

```
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 1 / 0;
Query OK, 1 row affected (0.00 sec)

mysql> SELECT i FROM t;
+-----+
| i     |
+-----+
| NULL  |
+-----+
1 row in set (0.03 sec)
```

However, division by zero is an error if the proper SQL modes are in effect:

```
mysql> SET sql_mode='STRICT_ALL_TABLES,ERROR_FOR_DIVISION_BY_ZERO';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 1 / 0;
ERROR 1365 (22012): Division by 0

mysql> SELECT i FROM t;
Empty set (0.01 sec)
```

Example 6. Prior to MySQL 5.0.3 (before precision math was introduced), exact-value and approximate-value literals both are converted to double-precision floating-point values:

```
mysql> SELECT VERSION();
+-----+
| VERSION() |
```

```
+-----+
| 4.1.18-log |
+-----+
1 row in set (0.01 sec)

mysql> CREATE TABLE t SELECT 2.5 AS a, 25E-1 AS b;
Query OK, 1 row affected (0.07 sec)
Records: 1 Duplicates: 0 Warnings: 0

mysql> DESCRIBE t;
+-----+
| Field | Type          | Null | Key | Default | Extra |
+-----+
| a      | double(3,1)   |      |     | 0.0     |       |
| b      | double        |      |     | 0       |       |
+-----+
2 rows in set (0.04 sec)
```

As of MySQL 5.0.3, the approximate-value literal still is converted to floating-point, but the exact-value literal is handled as **DECIMAL**:

```
mysql> SELECT VERSION();
+-----+
| VERSION() |
+-----+
| 5.1.6-alpha-log |
+-----+
1 row in set (0.11 sec)

mysql> CREATE TABLE t SELECT 2.5 AS a, 25E-1 AS b;
Query OK, 1 row affected (0.01 sec)
Records: 1 Duplicates: 0 Warnings: 0

mysql> DESCRIBE t;
+-----+
| Field | Type          | Null | Key | Default | Extra |
+-----+
| a      | decimal(2,1) unsigned | NO   |     | 0.0     |       |
| b      | double        | NO   |     | 0       |       |
+-----+
2 rows in set (0.01 sec)
```

Example 7. If the argument to an aggregate function is an exact numeric type, the result is also an exact numeric type, with a scale at least that of the argument.

Consider these statements:

```
mysql> CREATE TABLE t (i INT, d DECIMAL, f FLOAT);
mysql> INSERT INTO t VALUES(1,1,1);
mysql> CREATE TABLE y SELECT AVG(i), AVG(d), AVG(f) FROM t;
```

Result before MySQL 5.0.3 (prior to the introduction of precision math in MySQL):

```
mysql> DESCRIBE y;
+-----+
| Field | Type          | Null | Key | Default | Extra |
+-----+
| AVG(i) | double(17,4)  | YES  |     | NULL    |       |
| AVG(d) | double(17,4)  | YES  |     | NULL    |       |
| AVG(f) | double        | YES  |     | NULL    |       |
+-----+
```

The result is a double no matter the argument type.

Result as of MySQL 5.0.3:

```
mysql> DESCRIBE y;
+-----+
| Field | Type          | Null | Key | Default | Extra |
+-----+
| AVG(i) | decimal(14,4) | YES  |     | NULL    |       |
| AVG(d) | decimal(14,4) | YES  |     | NULL    |       |
| AVG(f) | double        | YES  |     | NULL    |       |
+-----+
```

The result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type.

Chapter 25. APIs and Libraries

This chapter describes the APIs available for MySQL, where to get them, and how to use them. The C API is the most extensively covered, because it was developed by the MySQL team, and is the basis for most of the other APIs. This chapter also covers the `libmysqld` library (the embedded server), as well as some programs that are useful for application developers.

25.1. libmysqld, the Embedded MySQL Server Library

25.1.1. Overview of the Embedded MySQL Server Library

The embedded MySQL server library makes it possible to run a full-featured MySQL server inside a client application. The main benefits are increased speed and more simple management for embedded applications.

The embedded server library is based on the client/server version of MySQL, which is written in C/C++. Consequently, the embedded server also is written in C/C++. There is no embedded server available in other languages.

The API is identical for the embedded MySQL version and the client/server version. To change an old threaded application to use the embedded library, you normally only have to add calls to the following functions:

Function	When to Call
<code>mysql_library_init()</code>	Should be called before any other MySQL function is called, preferably early in the <code>main()</code> function.
<code>mysql_library_end()</code>	Should be called before your program exits.
<code>mysql_thread_init()</code>	Should be called in each thread you create that accesses MySQL.
<code>mysql_thread_end()</code>	Should be called before calling <code>pthread_exit()</code>

Then you must link your code with `libmysqld.a` instead of `libmysqlclient.a`. To ensure binary compatibility between your application and the server library, be sure to compile your application against headers for the same series of MySQL that was used to compile the server library. For example, if `libmysqld` was compiled against MySQL 4.1 headers, do not compile your application against MySQL 5.1 headers, or vice versa.

The `mysql_library_xxx()` functions are also included in `libmysqlclient.a` to allow you to change between the embedded and the client/server version by just linking your application with the right library. See [Section 25.2.3.40](#), “`mysql_library_init()`”.

One difference between the embedded server and the standalone server is that for the embedded server, authentication for connections is disabled by default. To use authentication for the embedded server, specify the `--with-embedded-privilege-control` option when you invoke `configure` to configure your MySQL distribution.

25.1.2. Compiling Programs with `libmysqld`

To get a `libmysqld` library you should configure MySQL with the `--with-embedded-server` option. See [Section 2.9.2](#), “Typical configure Options”.

When you link your program with `libmysqld`, you must also include the system-specific `pthread` libraries and some libraries that the MySQL server uses. You can get the full list of libraries by executing `mysql_config --libmysqld-libs`.

The correct flags for compiling and linking a threaded program must be used, even if you do not directly call any thread functions in your code.

To compile a C program to include the necessary files to embed the MySQL server library into a compiled version of a program, use the GNU C compiler (`gcc`). The compiler will need to know where to find various files and need instructions on how to compile the program. The following example shows how a program could be compiled from the command line:

```
gcc mysql_test.c -o mysql_test -lz \
/usr/local/mysql/bin/mysql_config --include --libmysqld-libs`
```

Immediately following the `gcc` command is the name of the uncompiled C program file. After it, the `-o` option is given to indicate that the file name that follows is the name that the compiler is to give to the output file, the compiled program. The next line of code tells the

compiler to obtain the location of the include files and libraries and other settings for the system on which it's compiled. Because of a problem with `mysql_config`, the option `-lz` (for compression) is added here. The `mysql_config` piece is contained in backticks, not single quotes.

25.1.3. Restrictions When Using the Embedded MySQL Server

The embedded server has the following limitations:

- No user-defined functions (UDFs).
- No stack trace on core dump.
- You cannot set this up as a master or a slave (no replication).
- Very large result sets may be unusable on low memory systems.
- You cannot connect to an embedded server from an outside process with sockets or TCP/IP. However, you can connect to an intermediate application, which in turn can connect to an embedded server on the behalf of a remote client or outside process.
- **InnoDB** is not reentrant in the embedded server and cannot be used for multiple connections, either successively or simultaneously.

Some of these limitations can be changed by editing the `mysql_embed.h` include file and recompiling MySQL.

25.1.4. Options with the Embedded Server

Any options that may be given with the `mysqld` server daemon, may be used with an embedded server library. Server options may be given in an array as an argument to the `mysql_library_init()`, which initializes the server. They also may be given in an option file like `my.cnf`. To specify an option file for a C program, use the `--defaults-file` option as one of the elements of the second argument of the `mysql_library_init()` function. See [Section 25.2.3.40](#), “`mysql_library_init()`”, for more information on the `mysql_library_init()` function.

Using option files can make it easier to switch between a client/server application and one where MySQL is embedded. Put common options under the `[server]` group. These are read by both MySQL versions. Client/server-specific options should go under the `[mysqld]` section. Put options specific to the embedded MySQL server library in the `[embedded]` section. Options specific to applications go under section labeled `[ApplicationName_SERVER]`. See [Section 4.3.2](#), “Using Option Files”.

25.1.5. Embedded Server Examples

These two example programs should work without any changes on a Linux or FreeBSD system. For other operating systems, minor changes are needed, mostly with file paths. These examples are designed to give enough details for you to understand the problem, without the clutter that is a necessary part of a real application. The first example is very straightforward. The second example is a little more advanced with some error checking. The first is followed by a command-line entry for compiling the program. The second is followed by a GNUmake file that may be used for compiling instead.

Example 1

`test1_libmysqld.c`

```
#include <stdio.h>
#include <stdlib.h>
#include <stdarg.h>
#include "mysql.h"

MYSQL *mysql;
MYSQL_RES *results;
MYSQL_ROW record;

static char *server_options[] = \
    { "mysql_test", "--defaults-file=my.cnf", NULL };
int num_elements = (sizeof(server_options) / sizeof(char *)) - 1;

static char *server_groups[] = { "libmysqld_server",
    "libmysqld_client", NULL };

int main(void)
{
    mysql_library_init(num_elements, server_options, server_groups);
    mysql = mysql_init(NULL);
    mysql_options(mysql, MYSQL_READ_DEFAULT_GROUP, "libmysqld_client");
```

```

mysql_options(mysql, MYSQL_OPT_USE_EMBEDDED_CONNECTION, NULL);
mysql_real_connect(mysql, NULL, NULL, NULL, "database1", 0, NULL, 0);
mysql_query(mysql, "SELECT column1, column2 FROM table1");
results = mysql_store_result(mysql);
while((record = mysql_fetch_row(results))) {
    printf("%s - %s \n", record[0], record[1]);
}
mysql_free_result(results);
mysql_close(mysql);
mysql_library_end();

return 0;
}

```

Here is the command line for compiling the above program:

```

gcc test1_libmysqld.c -o test1_libmysqld -lz \
/usr/local/mysql/bin/mysql_config --include --libmysqld-libs`

```

Example 2

To try out the example, create an `test2_libmysqld` directory at the same level as the MySQL source directory. Save the `test2_libmysqld.c` source and the `GNUmakefile` in the directory, and run GNU `make` from inside the `test2_libmysqld` directory.

test2_libmysqld.c

```

/*
 * A simple example client, using the embedded MySQL server library
 */

#include <mysql.h>
#include <stdarg.h>
#include <stdio.h>
#include <stdlib.h>

MYSQL *db_connect(const char *dbname);
void db_disconnect(MYSQL *db);
void db_do_query(MYSQL *db, const char *query);

const char *server_groups[] = {
    "test2_libmysqld_SERVER", "embedded", "server", NULL
};

int
main(int argc, char **argv)
{
    MYSQL *one, *two;

    /* mysql_library_init() must be called before any other mysql
     * functions.
     * You can use mysql_library_init(0, NULL, NULL), and it
     * initializes the server using groups = {
     *   "server", "embedded", NULL
     * }.
     * In your $HOME/.my.cnf file, you probably want to put:
     [test2_libmysqld_SERVER]
     language = /path/to/source/of/mysql/sql/share/english
     * You could, of course, modify argc and argv before passing
     * them to this function. Or you could create new ones in any
     * way you like. But all of the arguments in argv (except for
     * argv[0], which is the program name) should be valid options
     * for the MySQL server.
     * If you link this client against the normal mysqlclient
     * library, this function is just a stub that does nothing.
     */
    mysql_library_init(argc, argv, (char **)server_groups);

    one = db_connect("test");
    two = db_connect(NULL);

    db_do_query(one, "SHOW TABLE STATUS");
    db_do_query(two, "SHOW DATABASES");

```

```

mysql_close(two);
mysql_close(one);

/* This must be called after all other mysql functions */
mysql_library_end();

exit(EXIT_SUCCESS);
}

static void
die(MYSQL *db, char *fmt, ...)
{
    va_list ap;
    va_start(ap, fmt);
    vfprintf(stderr, fmt, ap);
    va_end(ap);
    (void)putc('\n', stderr);
    if (db)
        db_disconnect(db);
    exit(EXIT_FAILURE);
}

MYSQL *
db_connect(const char *dbname)
{
    MYSQL *db = mysql_init(NULL);
    if (!db)
        die(db, "mysql_init failed: no memory");
    /*
     * Notice that the client and server use separate group names.
     * This is critical, because the server does not accept the
     * client's options, and vice versa.
     */
    mysql_options(db, MYSQL_READ_DEFAULT_GROUP, "test2_libmysqld_CLIENT");
    if (!mysql_real_connect(db, NULL, NULL, NULL, dbname, 0, NULL, 0))
        die(db, "mysql_real_connect failed: %s", mysql_error(db));

    return db;
}

    rm -f $(targets) $(objects) *.core
```

25.1.6. Licensing the Embedded Server

We encourage everyone to promote free software by releasing code under the GPL or a compatible license. For those who are not able to do this, another option is to purchase a commercial license for the MySQL code from MySQL AB. For details, please see <http://www.mysql.com/company/legal/licensing/>.

25.2. MySQL C API

The C API code is distributed with MySQL. It is included in the `mysqlclient` library and allows C programs to access a database.

Many of the clients in the MySQL source distribution are written in C. If you are looking for examples that demonstrate how to use the C API, take a look at these clients. You can find these in the `clients` directory in the MySQL source distribution.

Most of the other client APIs (all except Connector/J and Connector/NET) use the `mysqlclient` library to communicate with the MySQL server. This means that, for example, you can take advantage of many of the same environment variables that are used by other client programs, because they are referenced from the library. See [Chapter 7, Client and Utility Programs](#), for a list of these variables.

The client has a maximum communication buffer size. The size of the buffer that is allocated initially (16KB) is automatically increased up to the maximum size (the maximum is 16MB). Because buffer sizes are increased only as demand warrants, simply increasing the default maximum limit does not in itself cause more resources to be used. This size check is mostly a check for erroneous statements and communication packets.

The communication buffer must be large enough to contain a single SQL statement (for client-to-server traffic) and one row of returned data (for server-to-client traffic). Each thread's communication buffer is dynamically enlarged to handle any query or row up to the maximum limit. For example, if you have `BLOB` values that contain up to 16MB of data, you must have a communication buffer limit of at least 16MB (in both server and client). The client's default maximum is 16MB, but the default maximum in the server is 1MB. You can increase this by changing the value of the `max_allowed_packet` parameter when the server is started. See [Section 6.5.2, "Tuning Server Parameters"](#).

The MySQL server shrinks each communication buffer to `net_buffer_length` bytes after each query. For clients, the size of the buffer associated with a connection is not decreased until the connection is closed, at which time client memory is reclaimed.

For programming with threads, see [Section 25.2.16, "How to Make a Threaded Client"](#). For creating a standalone application which includes the "server" and "client" in the same program (and does not communicate with an external MySQL server), see [Section 25.1, "libmysqld, the Embedded MySQL Server Library"](#).

MySQL Enterprise

MySQL Enterprise subscribers will find more information about using the C API in the Knowledge Base articles, [The C API](#). Access to the MySQL Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information see <http://www.mysql.com/products/enterprise/advisors.html>.

25.2.1. C API Data types

- `MYSQL`

This structure represents a handle to one database connection. It is used for almost all MySQL functions. You should not try to make a copy of a `MYSQL` structure. There is no guarantee that such a copy will be usable.

- `MYSQL_RES`

This structure represents the result of a query that returns rows (`SELECT`, `SHOW`, `DESCRIBE`, `EXPLAIN`). The information returned from a query is called the *result set* in the remainder of this section.

- `MYSQL_ROW`

This is a type-safe representation of one row of data. It is currently implemented as an array of counted byte strings. (You cannot treat these as null-terminated strings if field values may contain binary data, because such values may contain null bytes internally.) Rows are obtained by calling `mysql_fetch_row()`.

- `MYSQL_FIELD`

This structure contains information about a field, such as the field's name, type, and size. Its members are described in more detail here. You may obtain the `MYSQL_FIELD` structures for each field by calling `mysql_fetch_field()` repeatedly. Field values are not part of this structure; they are contained in a `MYSQL_ROW` structure.

- `MYSQL_FIELD_OFFSET`

This is a type-safe representation of an offset into a MySQL field list. (Used by `mysql_field_seek()`.) Offsets are field numbers within a row, beginning at zero.

- `my_ulonglong`

The type used for the number of rows and for `mysql_affected_rows()`, `mysql_num_rows()`, and `mysql_insert_id()`. This type provides a range of 0 to 1.84e19.

On some systems, attempting to print a value of type `my_ulonglong` does not work. To print such a value, convert it to `unsigned long` and use a `%lu` print format. Example:

```
printf ("Number of rows: %lu\n",
        (unsigned long) mysql_num_rows(result));
```

- `my_bool`

A boolean type, for values that are true (non-zero) or false (zero).

The `MYSQL_FIELD` structure contains the members listed here:

- `char * name`

The name of the field, as a null-terminated string. If the field was given an alias with an `AS` clause, the value of `name` is the alias.

- `char * org_name`

The name of the field, as a null-terminated string. Aliases are ignored.

- `char * table`

The name of the table containing this field, if it isn't a calculated field. For calculated fields, the `table` value is an empty string. If the column is selected from a view, `table` names the view. If the table or view was given an alias with an `AS` clause, the value of `table` is the alias.

- `char * org_table`

The name of the table, as a null-terminated string. Aliases are ignored. If the column is selected from a view, `org_table` names the underlying table.

- `char * db`

The name of the database that the field comes from, as a null-terminated string. If the field is a calculated field, `db` is an empty string.

- `char * catalog`

The catalog name. This value is always `"def"`.

- `char * def`

The default value of this field, as a null-terminated string. This is set only if you use `mysql_list_fields()`.

- `unsigned long length`

The width of the field. This corresponds to the display length, in bytes.

- `unsigned long max_length`

The maximum width of the field for the result set (the length in bytes of the longest field value for the rows actually in the result set). If you use `mysql_store_result()` or `mysql_list_fields()`, this contains the maximum length for the field. If you use `mysql_use_result()`, the value of this variable is zero.

The value of `max_length` is the length of the string representation of the values in the result set. For example, if you retrieve a `FLOAT` column and the “widest” value is `-12.345`, `max_length` is 7 (the length of `'-12.345'`).

If you are using prepared statements, `max_length` is not set by default because for the binary protocol the lengths of the values depend on the types of the values in the result set. (See [Section 25.2.5, “C API Prepared Statement Data types”](#).) If you want the `max_length` values anyway, enable the `STMT_ATTR_UPDATE_MAX_LENGTH` option with `mysql_stmt_attr_set()` and the lengths will be set when you call `mysql_stmt_store_result()`. (See [Section 25.2.7.3, “mysql_stmt_attr_set\(\)”](#), and [Section 25.2.7.27, “mysql_stmt_store_result\(\)”](#).)

- `unsigned int name_length`

The length of `name`.

- `unsigned int org_name_length`

The length of `org_name`.

- `unsigned int table_length`

The length of `table`.

- `unsigned int org_table_length`

The length of `org_table`.

- `unsigned int db_length`

The length of `db`.

- `unsigned int catalog_length`

The length of `catalog`.

- `unsigned int def_length`

The length of `def`.

- `unsigned int flags`

Different bit-flags for the field. The `flags` value may have zero or more of the following bits set:

Flag Value	Flag Description
<code>NOT_NULL_FLAG</code>	Field can't be <code>NULL</code>
<code>PRI_KEY_FLAG</code>	Field is part of a primary key

<code>UNIQUE_KEY_FLAG</code>	Field is part of a unique key
<code>MULTIPLE_KEY_FLAG</code>	Field is part of a non-unique key
<code>UNSIGNED_FLAG</code>	Field has the <code>UNSIGNED</code> attribute
<code>ZEROFILL_FLAG</code>	Field has the <code>ZEROFILL</code> attribute
<code>BINARY_FLAG</code>	Field has the <code>BINARY</code> attribute
<code>AUTO_INCREMENT_FLAG</code>	Field has the <code>AUTO_INCREMENT</code> attribute
<code>ENUM_FLAG</code>	Field is an <code>ENUM</code> (deprecated)
<code>SET_FLAG</code>	Field is a <code>SET</code> (deprecated)
<code>BLOB_FLAG</code>	Field is a <code>BLOB</code> or <code>TEXT</code> (deprecated)
<code>TIMESTAMP_FLAG</code>	Field is a <code>TIMESTAMP</code> (deprecated)
<code>NO_DEFAULT_VALUE_FLAG</code>	Field has no default value; see additional notes following table

Use of the `BLOB_FLAG`, `ENUM_FLAG`, `SET_FLAG`, and `TIMESTAMP_FLAG` flags is deprecated because they indicate the type of a field rather than an attribute of its type. It is preferable to test `field->type` against `MYSQL_TYPE_BLOB`, `MYSQL_TYPE_ENUM`, `MYSQL_TYPE_SET`, or `MYSQL_TYPE_TIMESTAMP` instead.

`NUM_FLAG` indicates that a column is numeric. This includes columns with a type of `MYSQL_TYPE_DECIMAL`, `MYSQL_TYPE_TINY`, `MYSQL_TYPE_SHORT`, `MYSQL_TYPE_LONG`, `MYSQL_TYPE_FLOAT`, `MYSQL_TYPE_DOUBLE`, `MYSQL_TYPE_NULL`, `MYSQL_TYPE_TIMESTAMP`, `MYSQL_TYPE_LONGLONG`, `MYSQL_TYPE_INT24`, and `MYSQL_TYPE_YEAR`.

`NO_DEFAULT_VALUE_FLAG` indicates that a column has no `DEFAULT` clause in its definition. This does not apply to `NULL` columns (because such columns have a default of `NULL`), or to `AUTO_INCREMENT` columns (which have an implied default value).

The following example illustrates a typical use of the `flags` value:

```
if (field->flags & NOT_NULL_FLAG)
    printf("Field can't be null\n");
```

You may use the following convenience macros to determine the boolean status of the `flags` value:

Flag Status	Description
<code>IS_NOT_NULL(flags)</code>	True if this field is defined as <code>NOT NULL</code>
<code>IS_PRI_KEY(flags)</code>	True if this field is a primary key
<code>IS_BLOB(flags)</code>	True if this field is a <code>BLOB</code> or <code>TEXT</code> (deprecated; test <code>field->type</code> instead)

- `unsigned int decimals`

The number of decimals for numeric fields.

- `unsigned int charsetnr`

The character set number for the field.

- `enum enum_field_types type`

The type of the field. The `type` value may be one of the `MYSQL_TYPE_` symbols shown in the following table.

Type Value	Type Description
<code>MYSQL_TYPE_TINY</code>	<code>TINYINT</code> field
<code>MYSQL_TYPE_SHORT</code>	<code>SMALLINT</code> field
<code>MYSQL_TYPE_LONG</code>	<code>INTEGER</code> field
<code>MYSQL_TYPE_INT24</code>	<code>MEDIUMINT</code> field
<code>MYSQL_TYPE_LONGLONG</code>	<code>BIGINT</code> field

<code>MYSQL_TYPE_DECIMAL</code>	<code>DECIMAL</code> or <code>NUMERIC</code> field
<code>MYSQL_TYPE_NEWDECIMAL</code>	Precision math <code>DECIMAL</code> or <code>NUMERIC</code>
<code>MYSQL_TYPE_FLOAT</code>	<code>FLOAT</code> field
<code>MYSQL_TYPE_DOUBLE</code>	<code>DOUBLE</code> or <code>REAL</code> field
<code>MYSQL_TYPE_BIT</code>	<code>BIT</code> field
<code>MYSQL_TYPE_TIMESTAMP</code>	<code>TIMESTAMP</code> field
<code>MYSQL_TYPE_DATE</code>	<code>DATE</code> field
<code>MYSQL_TYPE_TIME</code>	<code>TIME</code> field
<code>MYSQL_TYPE_DATETIME</code>	<code>DATETIME</code> field
<code>MYSQL_TYPE_YEAR</code>	<code>YEAR</code> field
<code>MYSQL_TYPE_STRING</code>	<code>CHAR</code> or <code>BINARY</code> field
<code>MYSQL_TYPE_VAR_STRING</code>	<code>VARCHAR</code> or <code>VARBINARY</code> field
<code>MYSQL_TYPE_BLOB</code>	<code>BLOB</code> or <code>TEXT</code> field (use <code>max_length</code> to determine the maximum length)
<code>MYSQL_TYPE_SET</code>	<code>SET</code> field
<code>MYSQL_TYPE_ENUM</code>	<code>ENUM</code> field
<code>MYSQL_TYPE_GEOMETRY</code>	Spatial field
<code>MYSQL_TYPE_NULL</code>	<code>NULL</code> -type field

You can use the `IS_NUM()` macro to test whether a field has a numeric type. Pass the `type` value to `IS_NUM()` and it evaluates to TRUE if the field is numeric:

```
if (IS_NUM(field->type))
    printf("Field is numeric\n");
```

To distinguish between binary and non-binary data for string data types, check whether the `charsetnr` value is 63. If so, the character set is `binary`, which indicates binary rather than non-binary data. This is how to distinguish between `BINARY` and `CHAR`, `VARBINARY` and `VARCHAR`, and `BLOB` and `TEXT`.

25.2.2. C API Function Overview

The functions available in the C API are summarized here and described in greater detail in a later section. See [Section 25.2.3, “C API Function Descriptions”](#).

Function	Description
<code>my_init()</code>	Initialize global variables, and thread handler in thread-safe programs.
<code>mysql_affected_rows()</code>	Returns the number of rows changed/deleted/inserted by the last <code>UPDATE</code> , <code>DELETE</code> , or <code>INSERT</code> query.
<code>mysql_autocommit()</code>	Toggles autocommit mode on/off.
<code>mysql_change_user()</code>	Changes user and database on an open connection.
<code>mysql_close()</code>	Closes a server connection.
<code>mysql_commit()</code>	Commits the transaction.
<code>mysql_connect()</code>	Connects to a MySQL server. This function is deprecated; use <code>mysql_real_connect()</code> instead.
<code>mysql_create_db()</code>	Creates a database. This function is deprecated; use the SQL statement <code>CREATE DATABASE</code> instead.
<code>mysql_data_seek()</code>	Seeks to an arbitrary row number in a query result set.
<code>mysql_debug()</code>	Does a <code>DEBUG_PUSH</code> with the given string.
<code>mysql_drop_db()</code>	Drops a database. This function is deprecated; use the SQL statement <code>DROP DATABASE</code> instead.

mysql_dump_debug_info()	Makes the server write debug information to the log.
mysql_eof()	Determines whether the last row of a result set has been read. This function is deprecated; mysql_errno() or mysql_error() may be used instead.
mysql_errno()	Returns the error number for the most recently invoked MySQL function.
mysql_error()	Returns the error message for the most recently invoked MySQL function.
mysql_escape_string()	Escapes special characters in a string for use in an SQL statement.
mysql_fetch_field()	Returns the type of the next table field.
mysql_fetch_field_direct()	Returns the type of a table field, given a field number.
mysql_fetch_fields()	Returns an array of all field structures.
mysql_fetch_lengths()	Returns the lengths of all columns in the current row.
mysql_fetch_row()	Fetches the next row from the result set.
mysql_field_seek()	Puts the column cursor on a specified column.
mysql_field_count()	Returns the number of result columns for the most recent statement.
mysql_field_tell()	Returns the position of the field cursor used for the last mysql_fetch_field() .
mysql_free_result()	Frees memory used by a result set.
mysql_get_client_info()	Returns client version information as a string.
mysql_get_client_version()	Returns client version information as an integer.
mysql_get_host_info()	Returns a string describing the connection.
mysql_get_server_version()	Returns version number of server as an integer.
mysql_get_proto_info()	Returns the protocol version used by the connection.
mysql_get_server_info()	Returns the server version number.
mysql_info()	Returns information about the most recently executed query.
mysql_init()	Gets or initializes a MYSQL structure.
mysql_insert_id()	Returns the ID generated for an AUTO_INCREMENT column by the previous query.
mysql_kill()	Kills a given thread.
mysql_library_end()	Finalize the MySQL C API library.
mysql_library_init()	Initialize the MySQL C API library.
mysql_list_dbs()	Returns database names matching a simple regular expression.
mysql_list_fields()	Returns field names matching a simple regular expression.
mysql_list_processes()	Returns a list of the current server threads.
mysql_list_tables()	Returns table names matching a simple regular expression.
mysql_more_results()	Checks whether any more results exist.
mysql_next_result()	Returns/initiates the next result in multiple-statement executions.
mysql_num_fields()	Returns the number of columns in a result set.
mysql_num_rows()	Returns the number of rows in a result set.
mysql_options()	Sets connect options for mysql_connect() .
mysql_ping()	Checks whether the connection to the server is working, reconnecting as necessary.
mysql_query()	Executes an SQL query specified as a null-terminated string.
mysql_real_connect()	Connects to a MySQL server.
mysql_real_escape_string()	Escapes special characters in a string for use in an SQL statement, taking into account the current character set of the connection.
mysql_real_query()	Executes an SQL query specified as a counted string.
mysql_refresh()	Flush or reset tables and caches.
mysql_reload()	Tells the server to reload the grant tables.
mysql_rollback()	Rolls back the transaction.

mysql_row_seek()	Seeks to a row offset in a result set, using value returned from mysql_row_tell() .
mysql_row_tell()	Returns the row cursor position.
mysql_select_db()	Selects a database.
mysql_server_end()	Finalize the MySQL C API library.
mysql_server_init()	Initialize the MySQL C API library.
mysql_set_local_infile_default()	Set the LOAD DATA LOCAL INFILE handler callbacks to their default values.
mysql_set_local_infile_handler()	Install application-specific LOAD DATA LOCAL INFILE handler callbacks.
mysql_set_server_option()	Sets an option for the connection (like multi-statements).
mysql_sqlstate()	Returns the SQLSTATE error code for the last error.
mysql_shutdown()	Shuts down the database server.
mysql_stat()	Returns the server status as a string.
mysql_store_result()	Retrieves a complete result set to the client.
mysql_thread_end()	Finalize thread handler.
mysql_thread_id()	Returns the current thread ID.
mysql_thread_init()	Initialize thread handler.
mysql_thread_safe()	Returns 1 if the clients are compiled as thread-safe.
mysql_use_result()	Initiates a row-by-row result set retrieval.
mysql_warning_count()	Returns the warning count for the previous SQL statement.

Application programs should use this general outline for interacting with MySQL:

1. Initialize the MySQL library by calling [mysql_library_init\(\)](#). This function exists in both the [mysqlclient](#) C client library and the [mysqld](#) embedded server library, so it is used whether you build a regular client program by linking with the [-libmysqlclient](#) flag, or an embedded server application by linking with the [-libmysqld](#) flag.
2. Initialize a connection handler by calling [mysql_init\(\)](#) and connect to the server by calling [mysql_real_connect\(\)](#).
3. Issue SQL statements and process their results. (The following discussion provides more information about how to do this.)
4. Close the connection to the MySQL server by calling [mysql_close\(\)](#).
5. End use of the MySQL library by calling [mysql_library_end\(\)](#).

The purpose of calling [mysql_library_init\(\)](#) and [mysql_library_end\(\)](#) is to provide proper initialization and finalization of the MySQL library. For applications that are linked with the client library, they provide improved memory management. If you don't call [mysql_library_end\(\)](#), a block of memory remains allocated. (This does not increase the amount of memory used by the application, but some memory leak detectors will complain about it.) For applications that are linked with the embedded server, these calls start and stop the server.

In a non-multi-threaded environment, the call to [mysql_library_init\(\)](#) may be omitted, because [mysql_init\(\)](#) will invoke it automatically as necessary. However, [mysql_library_init\(\)](#) is not thread-safe in a multi-threaded environment, and thus neither is [mysql_init\(\)](#), which calls [mysql_library_init\(\)](#). You must either call [mysql_library_init\(\)](#) prior to spawning any threads, or else use a mutex to protect the call, whether you invoke [mysql_library_init\(\)](#) or indirectly via [mysql_init\(\)](#). This should be done prior to any other client library call.

To connect to the server, call [mysql_init\(\)](#) to initialize a connection handler, then call [mysql_real_connect\(\)](#) with that handler (along with other information such as the hostname, username, and password). Upon connection, [mysql_real_connect\(\)](#) sets the [reconnect](#) flag (part of the [MYSQL](#) structure) to a value of [1](#) in versions of the API older than 5.0.3, or [0](#) in newer versions. A value of [1](#) for this flag indicates that if a statement cannot be performed because of a lost connection, to try reconnecting to the server before giving up. You can use the [MYSQL_OPT_RECONNECT](#) option to [mysql_options\(\)](#) to control reconnection behavior. When you are done with the connection, call [mysql_close\(\)](#) to terminate it.

While a connection is active, the client may send SQL statements to the server using [mysql_query\(\)](#) or [mysql_real_query\(\)](#). The difference between the two is that [mysql_query\(\)](#) expects the query to be specified as a null-terminated string whereas

`mysql_real_query()` expects a counted string. If the string contains binary data (which may include null bytes), you must use `mysql_real_query()`.

For each non-**SELECT** query (for example, **INSERT**, **UPDATE**, **DELETE**), you can find out how many rows were changed (affected) by calling `mysql_affected_rows()`.

For **SELECT** queries, you retrieve the selected rows as a result set. (Note that some statements are **SELECT**-like in that they return rows. These include **SHOW**, **DESCRIBE**, and **EXPLAIN**. They should be treated the same way as **SELECT** statements.)

There are two ways for a client to process result sets. One way is to retrieve the entire result set all at once by calling `mysql_store_result()`. This function acquires from the server all the rows returned by the query and stores them in the client. The second way is for the client to initiate a row-by-row result set retrieval by calling `mysql_use_result()`. This function initializes the retrieval, but does not actually get any rows from the server.

In both cases, you access rows by calling `mysql_fetch_row()`. With `mysql_store_result()`, `mysql_fetch_row()` accesses rows that have previously been fetched from the server. With `mysql_use_result()`, `mysql_fetch_row()` actually retrieves the row from the server. Information about the size of the data in each row is available by calling `mysql_fetch_lengths()`.

After you are done with a result set, call `mysql_free_result()` to free the memory used for it.

The two retrieval mechanisms are complementary. Client programs should choose the approach that is most appropriate for their requirements. In practice, clients tend to use `mysql_store_result()` more commonly.

An advantage of `mysql_store_result()` is that because the rows have all been fetched to the client, you not only can access rows sequentially, you can move back and forth in the result set using `mysql_data_seek()` or `mysql_row_seek()` to change the current row position within the result set. You can also find out how many rows there are by calling `mysql_num_rows()`. On the other hand, the memory requirements for `mysql_store_result()` may be very high for large result sets and you are more likely to encounter out-of-memory conditions.

An advantage of `mysql_use_result()` is that the client requires less memory for the result set because it maintains only one row at a time (and because there is less allocation overhead, `mysql_use_result()` can be faster). Disadvantages are that you must process each row quickly to avoid tying up the server, you don't have random access to rows within the result set (you can only access rows sequentially), and you don't know how many rows are in the result set until you have retrieved them all. Furthermore, you **must** retrieve all the rows even if you determine in mid-retrieval that you've found the information you were looking for.

The API makes it possible for clients to respond appropriately to statements (retrieving rows only as necessary) without knowing whether the statement is a **SELECT**. You can do this by calling `mysql_store_result()` after each `mysql_query()` (or `mysql_real_query()`). If the result set call succeeds, the statement was a **SELECT** and you can read the rows. If the result set call fails, call `mysql_field_count()` to determine whether a result was actually to be expected. If `mysql_field_count()` returns zero, the statement returned no data (indicating that it was an **INSERT**, **UPDATE**, **DELETE**, and so forth), and was not expected to return rows. If `mysql_field_count()` is non-zero, the statement should have returned rows, but didn't. This indicates that the statement was a **SELECT** that failed. See the description for `mysql_field_count()` for an example of how this can be done.

Both `mysql_store_result()` and `mysql_use_result()` allow you to obtain information about the fields that make up the result set (the number of fields, their names and types, and so forth). You can access field information sequentially within the row by calling `mysql_fetch_field()` repeatedly, or by field number within the row by calling `mysql_fetch_field_direct()`. The current field cursor position may be changed by calling `mysql_field_seek()`. Setting the field cursor affects subsequent calls to `mysql_fetch_field()`. You can also get information for fields all at once by calling `mysql_fetch_fields()`.

For detecting and reporting errors, MySQL provides access to error information by means of the `mysql_errno()` and `mysql_error()` functions. These return the error code or error message for the most recently invoked function that can succeed or fail, allowing you to determine when an error occurred and what it was.

25.2.3. C API Function Descriptions

In the descriptions here, a parameter or return value of **NULL** means **NULL** in the sense of the C programming language, not a MySQL **NULL** value.

Functions that return a value generally return a pointer or an integer. Unless specified otherwise, functions returning a pointer return a non-**NULL** value to indicate success or a **NULL** value to indicate an error, and functions returning an integer return zero to indicate success or non-zero to indicate an error. Note that “non-zero” means just that. Unless the function description says otherwise, do not test against a value other than zero:

```
if (result)                /* correct */
    ... error ...
```

```
if (result < 0)           /* incorrect */
    ... error ...

if (result == -1)        /* incorrect */
    ... error ...
```

When a function returns an error, the **Errors** subsection of the function description lists the possible types of errors. You can find out which of these occurred by calling `mysql_errno()`. A string representation of the error may be obtained by calling `mysql_error()`.

MySQL Enterprise

MySQL Enterprise subscribers will find more information about the C API functions in the Knowledge Base articles, [The C API](#). Access to the MySQL Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information see <http://www.mysql.com/products/enterprise/advisors.html>.

25.2.3.1. `mysql_affected_rows()`

```
my_ulonglong mysql_affected_rows(MYSQL *mysql)
```

Description

After executing a statement with `mysql_query()` or `mysql_real_query()`, returns the number of rows changed (for `UPDATE`), deleted (for `DELETE`, or inserted (for `INSERT`. For `SELECT` statements, `mysql_affected_rows()` works like `mysql_num_rows()`.

Return Values

An integer greater than zero indicates the number of rows affected or retrieved. Zero indicates that no records were updated for an `UPDATE` statement, no rows matched the `WHERE` clause in the query or that no query has yet been executed. -1 indicates that the query returned an error or that, for a `SELECT` query, `mysql_affected_rows()` was called prior to calling `mysql_store_result()`. Because `mysql_affected_rows()` returns an unsigned value, you can check for -1 by comparing the return value to `(my_ulonglong)-1` (or to `(my_ulonglong)~0`, which is equivalent).

Errors

None.

Example

```
char *stmt = "UPDATE products SET cost=cost*1.25 WHERE group=10";
mysql_query(&mysql, stmt);
printf("%ld products updated",
       (long) mysql_affected_rows(&mysql));
```

For `UPDATE` statements, if you specify the `CLIENT_FOUND_ROWS` flag when connecting to `mysqld`, `mysql_affected_rows()` returns the number of rows matched by the `WHERE` clause. Otherwise, the default behavior is to return the number of rows actually changed.

Note that when you use a `REPLACE` command, `mysql_affected_rows()` returns 2 if the new row replaced an old row, because in this case, one row was inserted after the duplicate was deleted.

If you use `INSERT ... ON DUPLICATE KEY UPDATE` to insert a row, `mysql_affected_rows()` returns 1 if the row is inserted as a new row and 2 if an existing row is updated.

25.2.3.2. `mysql_autocommit()`

```
my_bool mysql_autocommit(MYSQL *mysql, my_bool mode)
```

Description

Sets autocommit mode on if `mode` is 1, off if `mode` is 0.

Return Values

Zero if successful. Non-zero if an error occurred.

Errors

None.

25.2.3.3. `mysql_change_user()`

```
my_bool mysql_change_user(MYSQL *mysql, const char *user, const char *password, const char *db)
```

Description

Changes the user and causes the database specified by `db` to become the default (current) database on the connection specified by `mysql`. In subsequent queries, this database is the default for table references that do not include an explicit database specifier.

`mysql_change_user()` fails if the connected user cannot be authenticated or doesn't have permission to use the database. In this case, the user and database are not changed

The `db` parameter may be set to `NULL` if you don't want to have a default database.

This command resets the state as if one had done a new connect. (See [Section 25.2.13, “Controlling Automatic Reconnect Behavior”](#).) It always performs a `ROLLBACK` of any active transactions, closes and drops all temporary tables, and unlocks all locked tables. Session system variables are reset to the values of the corresponding global system variables. Prepared statements are released and `HANDLER` variables are closed. Locks acquired with `GET_LOCK()` are released. These effects occur even if the user didn't change.

Return Values

Zero for success. Non-zero if an error occurred.

Errors

The same that you can get from `mysql_real_connect()`.

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_SERVER_LOST`
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.
- `ER_UNKNOWN_COM_ERROR`
The MySQL server doesn't implement this command (probably an old server).
- `ER_ACCESS_DENIED_ERROR`
The user or password was wrong.
- `ER_BAD_DB_ERROR`
The database didn't exist.
- `ER_DBACCESS_DENIED_ERROR`
The user did not have access rights to the database.
- `ER_WRONG_DB_NAME`

The database name was too long.

Example

```
if (mysql_change_user(&mysql, "user", "password", "new_database"))
{
    fprintf(stderr, "Failed to change user.  Error: %s\n",
        mysql_error(&mysql));
}
```

25.2.3.4. `mysql_character_set_name()`

```
const char *mysql_character_set_name(MYSQL *mysql)
```

Description

Returns the default character set for the current connection.

Return Values

The default character set

Errors

None.

25.2.3.5. `mysql_close()`

```
void mysql_close(MYSQL *mysql)
```

Description

Closes a previously opened connection. `mysql_close()` also deallocates the connection handle pointed to by `mysql` if the handle was allocated automatically by `mysql_init()` or `mysql_connect()`.

Return Values

None.

Errors

None.

25.2.3.6. `mysql_commit()`

```
my_bool mysql_commit(MYSQL *mysql)
```

Description

Commits the current transaction.

The action of this function is subject to the value of the `completion_type` system variable. In particular, if the value of `completion_type` is 2, the server performs a release after terminating a transaction and closes the client connection. The client program should call `mysql_close()` to close the connection from the client side.

Return Values

Zero if successful. Non-zero if an error occurred.

Errors

None.

25.2.3.7. `mysql_connect()`

```
MYSQL *mysql_connect(MYSQL *mysql, const char *host, const char *user, const char *passwd)
```

Description

This function is deprecated. It is preferable to use `mysql_real_connect()` instead.

`mysql_connect()` attempts to establish a connection to a MySQL database engine running on `host`. `mysql_connect()` must complete successfully before you can execute any of the other API functions, with the exception of `mysql_get_client_info()`.

The meanings of the parameters are the same as for the corresponding parameters for `mysql_real_connect()` with the difference that the connection parameter may be `NULL`. In this case, the C API allocates memory for the connection structure automatically and frees it when you call `mysql_close()`. The disadvantage of this approach is that you can't retrieve an error message if the connection fails. (To get error information from `mysql_errno()` or `mysql_error()`, you must provide a valid `MYSQL` pointer.)

Return Values

Same as for `mysql_real_connect()`.

Errors

Same as for `mysql_real_connect()`.

25.2.3.8. `mysql_create_db()`

```
int mysql_create_db(MYSQL *mysql, const char *db)
```

Description

Creates the database named by the `db` parameter.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL `CREATE DATABASE` statement instead.

Return Values

Zero if the database was created successfully. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_SERVER_LOST`
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.

Example

```
if(mysql_create_db(&mysql, "my_database"))
{
    fprintf(stderr, "Failed to create new database. Error: %s\n",
            mysql_error(&mysql));
}
```

25.2.3.9. `mysql_data_seek()`

```
void mysql_data_seek(MYSQL_RES *result, my_ulonglong offset)
```

Description

Seeks to an arbitrary row in a query result set. The `offset` value is a row number and should be in the range from `0` to `mysql_num_rows(result)-1`.

This function requires that the result set structure contains the entire result of the query, so `mysql_data_seek()` may be used only in conjunction with `mysql_store_result()`, not with `mysql_use_result()`.

Return Values

None.

Errors

None.

25.2.3.10. `mysql_debug()`

```
void mysql_debug(const char *debug)
```

Description

Does a `DEBUG_PUSH` with the given string. `mysql_debug()` uses the Fred Fish debug library. To use this function, you must compile the client library to support debugging. See [MySQL Internals: Porting](#).

Return Values

None.

Errors

None.

Example

The call shown here causes the client library to generate a trace file in `/tmp/client.trace` on the client machine:

```
mysql_debug("d:t:0,/tmp/client.trace");
```

25.2.3.11. `mysql_drop_db()`

```
int mysql_drop_db(MYSQL *mysql, const char *db)
```

Description

Drops the database named by the `db` parameter.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL `DROP DATABASE` statement instead.

Return Values

Zero if the database was dropped successfully. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- [CR_UNKNOWN_ERROR](#)

An unknown error occurred.

Example

```
if(mysql_drop_db(&mysql, "my_database"))
    fprintf(stderr, "Failed to drop the database: Error: %s\n",
            mysql_error(&mysql));
```

25.2.3.12. [mysql_dump_debug_info\(\)](#)

```
int mysql_dump_debug_info(MYSQL *mysql)
```

Description

Instructs the server to write some debug information to the log. For this to work, the connected user must have the [SUPER](#) privilege.

Return Values

Zero if the command was successful. Non-zero if an error occurred.

Errors

- [CR_COMMANDS_OUT_OF_SYNC](#)

Commands were executed in an improper order.

- [CR_SERVER_GONE_ERROR](#)

The MySQL server has gone away.

- [CR_SERVER_LOST](#)

The connection to the server was lost during the query.

- [CR_UNKNOWN_ERROR](#)

An unknown error occurred.

25.2.3.13. [mysql_eof\(\)](#)

```
my_bool mysql_eof(MYSQL_RES *result)
```

Description

This function is deprecated. [mysql_errno\(\)](#) or [mysql_error\(\)](#) may be used instead.

[mysql_eof\(\)](#) determines whether the last row of a result set has been read.

If you acquire a result set from a successful call to [mysql_store_result\(\)](#), the client receives the entire set in one operation. In this case, a [NULL](#) return from [mysql_fetch_row\(\)](#) always means the end of the result set has been reached and it is unnecessary to call [mysql_eof\(\)](#). When used with [mysql_store_result\(\)](#), [mysql_eof\(\)](#) always returns true.

On the other hand, if you use [mysql_use_result\(\)](#) to initiate a result set retrieval, the rows of the set are obtained from the server one by one as you call [mysql_fetch_row\(\)](#) repeatedly. Because an error may occur on the connection during this process, a [NULL](#) return value from [mysql_fetch_row\(\)](#) does not necessarily mean the end of the result set was reached normally. In this case, you can use [mysql_eof\(\)](#) to determine what happened. [mysql_eof\(\)](#) returns a non-zero value if the end of the result set was reached and zero if an error occurred.

Historically, `mysql_eof()` predates the standard MySQL error functions `mysql_errno()` and `mysql_error()`. Because those error functions provide the same information, their use is preferred over `mysql_eof()`, which is deprecated. (In fact, they provide more information, because `mysql_eof()` returns only a boolean value whereas the error functions indicate a reason for the error when one occurs.)

Return Values

Zero if no error occurred. Non-zero if the end of the result set has been reached.

Errors

None.

Example

The following example shows how you might use `mysql_eof()`:

```
mysql_query(&mysql, "SELECT * FROM some_table");
result = mysql_use_result(&mysql);
while((row = mysql_fetch_row(result)))
{
    // do something with data
}
if(!mysql_eof(result)) // mysql_fetch_row() failed due to an error
{
    fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
}
```

However, you can achieve the same effect with the standard MySQL error functions:

```
mysql_query(&mysql, "SELECT * FROM some_table");
result = mysql_use_result(&mysql);
while((row = mysql_fetch_row(result)))
{
    // do something with data
}
if(mysql_errno(&mysql)) // mysql_fetch_row() failed due to an error
{
    fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
}
```

25.2.3.14. `mysql_errno()`

```
unsigned int mysql_errno(MYSQL *mysql)
```

Description

For the connection specified by `mysql`, `mysql_errno()` returns the error code for the most recently invoked API function that can succeed or fail. A return value of zero means that no error occurred. Client error message numbers are listed in the MySQL `errmsg.h` header file. Server error message numbers are listed in `mysqld_error.h`. Errors also are listed at [Appendix B, Errors, Error Codes, and Common Problems](#).

Note that some functions like `mysql_fetch_row()` don't set `mysql_errno()` if they succeed.

A rule of thumb is that all functions that have to ask the server for information reset `mysql_errno()` if they succeed.

MySQL-specific error numbers returned by `mysql_errno()` differ from SQLSTATE values returned by `mysql_sqlstate()`. For example, the `mysql` client program displays errors using the following format, where `1146` is the `mysql_errno()` value and `'42S02'` is the corresponding `mysql_sqlstate()` value:

```
shell> SELECT * FROM no_such_table;
ERROR 1146 (42S02): Table 'test.no_such_table' doesn't exist
```

Return Values

An error code value for the last `mysql_xxx()` call, if it failed. zero means no error occurred.

Errors

None.

25.2.3.15. `mysql_error()`

```
const char *mysql_error(MYSQL *mysql)
```

Description

For the connection specified by `mysql`, `mysql_error()` returns a null-terminated string containing the error message for the most recently invoked API function that failed. If a function didn't fail, the return value of `mysql_error()` may be the previous error or an empty string to indicate no error.

A rule of thumb is that all functions that have to ask the server for information reset `mysql_error()` if they succeed.

For functions that reset `mysql_error()`, the following two tests are equivalent:

```
if(*mysql_error(&mysql))
{
    // an error occurred
}

if(mysql_error(&mysql)[0])
{
    // an error occurred
}
```

The language of the client error messages may be changed by recompiling the MySQL client library. Currently, you can choose error messages in several different languages. See [Section 5.10.2, “Setting the Error Message Language”](#).

Return Values

A null-terminated character string that describes the error. An empty string if no error occurred.

Errors

None.

25.2.3.16. `mysql_escape_string()`

You should use `mysql_real_escape_string()` instead!
